PUBLICATION ETHICS AND MALPRACTICE STATEMENT

The conference Globalization and its socio-economic consequences fulfils the requirements of the publishing process, it recognizes the ethical responsibilities of all parties of the publication process. Thus, we take our duties of guardianship over all stages of publishing very seriously and we recognize our ethical duties and other responsibilities.

Editorial Board

The editor and the guarantees of the conference are recognized experts in their fields, their full names and affiliations are provided on the conference website in the section Home on the conference website. The contact information for the editorial team is on the conference website, section Contact on the conference website.

Authors and Authors responsibilities

The paper must be an original unpublished work written English, Slovak or Czech languages. The submitted paper should neither be published before nor be under consideration for publication in another conference proceedings or journal. Authors, whose names appear on the paper have contributed sufficiently to the scientific work and therefore share collective responsibility and accountability for the results. The content of the paper must correspond to the publishing strategy of the conference and the article must meet the other conditions given in the author's guidelines (section Important dates/ Author guidelines/ Forms on the conference website). There is a publication fee for the paper processing (section Conference fee on the conference website).

All papers are subjected to a double-blind, peer-review process. Firstly, each submission is reviewed by the conference editors, who may reject it, if it is not dealing with the subject matter of the conference and does not meet the conference requirements or if it is of a low quality. In the second stage of the review process, the paper is sent to two independent reviewers. Reviewers are asked to evaluate the paper and they may recommend to: (i) accept the paper in the current form, (ii) accept the paper with minor correction, (iii) accept the paper with major corrections, (iv) accept the paper only after corrections and repeated review, and (v) reject the paper. Reviewers include the recommendations and comments, which are then sent to the author(s). The editors should not reverse decisions on publication unless serious problems are identified.

Each paper must be submitted by e-mail to: globalizacia@fpedas.uniza.sk. The paper is successfully submitted if the author receives a confirmation e-mail.

Peer-review process

All submitted papers received by the editorial office are firstly checked by the editors to determine if they are properly prepared and follow the ethical policies of the conference. The editors are responsible for deciding which of the submitted papers should be published. The editors are guided by the policies of the conference editorial team and constrained by such legal requirements as copyright infringement and plagiarism. Papers that do not fit the ethics policy or do not meet the requirements of the conference will be rejected before the peer-review process. Papers that are not properly prepared will be returned to the authors for revision and resubmission.

Once a paper passes the editorial checks, it will be assigned to two independent experts for a double-blind peer-review. Judgements should be objective; reviewers should have no conflict of interest and should point out relevant published work which is not yet cited. Reviewed articles should be treated confidentially. Reviewers are asked to evaluate the paper and they may recommend to: (i) accept the paper in the current form, (ii) accept the paper

with minor correction, (iii) accept the paper with major corrections, (iv) accept the paper only after corrections and repeated review, and (v) reject the paper. The final decision to accept or reject the manuscript will also be sent to the corresponding author along with any recommendations made by the reviewers.

All reviewer comments should be responded to in a point-by-point fashion.

The editors and reviewers should evaluate manuscripts for their intellectual content without regard to race, gender, sexual orientation, religious belief, ethnic origin, citizenship, or political philosophy of the authors. The editors´ decision to accept or reject a paper for publication should be based only on the paper´s importance, originality and clarity, and the study´s relevance to the aim of the conference.

Publication ethics

The editors of the conference proceedings enforce a peer-review process together with ethical policies and standards to ensure to add high-quality scientific works to the field of scholarly publication.

Authors wishing to publish their papers in the conference proceedings must abide by the following:

- Any facts that might be perceived as a possible conflict of interest of the author(s) must be disclosed in the paper prior to submission.
- Authors should accurately present their research findings and include an objective discussion of the significance of their findings.
- Data and methods used in the research need to be presented in sufficient detail in the paper.
- Simultaneous submission of manuscripts to more than one conference proceedings or journal is not tolerated.
- Republishing content that is not novel is not tolerated.
- If errors and inaccuracies are found by the authors after publication of their paper or some corrections are to be made, they need to be promptly communicated to the editors of this conference so that appropriate actions can be taken.
- Plagiarism, data fabrication and image manipulation are not tolerated and the following measures will be taken accordingly. First, the manuscript that has been proven to be involved in plagiarism will be immediately rejected along with the immediate rejection of any other manuscript submitted by the same authors. Second, each author involved in the violating manuscript will be banned from submitting any new manuscript to the conference in a period of two years.

For any complaints or concerns with regard to any publishing article, please contact us at **globalizacia@fpedas.uniza.sk**. We will acknowledge your e-mail and provide an estimated time to study and solve your complaints or concerns.

Retraction and correction policy

The editors are committed to upholding the integrity of the literature and publishes editorially significant correction dependent on the situation. In all cases, the original articles will be removed and replaced with a note stating the reason of retraction and with the corrected version. If plagiarism is found, a whole article will be removed from the conference proceedings.

When an author discovers a significant error or inaccuracy in their own published work, it is the author´s obligation to promptly notify the conference editors or publisher and cooperate with the editors to retract or correct the paper. If the editors or the publisher learns

from a third party that a published work contains a significant error, it is the obligation of the author to promptly retract or correct the paper or provide evidence to the editor of the correctness of the original paper.

Originality and plagiarism

The authors should ensure that they have written entirely original works, and if the authors have used the work and/or words of others, then this has been appropriately cited or quoted. Plagiarism takes many forms, from rewriting another´s paper as the author´s own paper to copying or paraphrasing substantial parts of another paper (without attribution and citation), to claiming results from research conducted by others. Plagiarism in all its forms constitutes unethical publishing behaviour and is unacceptable.

Authorship of the paper

Authorship should be limited to those who have made a significant contribution to the conception, design, execution, or interpretation of the reported study. All those who have made significant contributions should be listed as co-authors. Where there are others who have participated in certain substantive aspects of the research project, they should be acknowledged or listed as contributors. The corresponding author should ensure that all appropriate co-authors and no inappropriate co-authors are included on the paper and that all co-authors have seen and approved the final version of the paper and have agreed to its submission for publication.

Copyright and Access

The author(s) must agree that the published version of the paper will be placed on the website of the conference (in pdf format) in the conference proceedings. Before an article goes to print, the author(s) must sign and return the copyright agreement (a scanned signed copy in pdf).

Archiving

The editors ensure digital preservation of access to the conference proceedings content on the conference website. All the printed issues of the conference proceedings are available in the registry and library of the Department of Economics, Faculty of Operation and Economics of Transport and Communications at the University of Zilina.

Website

The editors ensure that the conference website, including the text that it contains, demonstrates that care has been taken to ensure high ethical and professional standards.

Publishing schedule

Conference Globalization and its socio-economic consequences is a peer-reviewed scientific conference published by the University of Zilina.

Name of the conference

Conference Globalization and its socio-economic consequences is unique, and it cannot be easily confused with other conferences or misled potential authors and readers about the conference origin or association with other conferences.

TOPICS

GLOBAL IMPACT OF COVID 19 ON ECONOMY AND SOCIETY
- Impact of the coronavirus pandemic on individual economies
- Social and economic impacts of the pandemic on national economies
- Impact of COVID 19 on the operation and SMEs
- Consequences of COVID 19 on financial markets

BEHAVIORAL ECONOMICS AND DECISION-MAKING
- Accounting and taxes in global economy
- Business economics and finance
- Information systems
- Strategic management
- Marketing research and strategy

INDUSTRY 4.0
- Industry 4.0 Implication for Economy and Society
- Sectoral and intra-sectoral changes
- Business Information System

INNOVATION, COLLABORATIVE, AND CIRCULAR ECONOMY
- Collaborative Economy, main attributes and challenges
- Sharing economy business models
- Circular economy – benefits and barriers
- Innovation, Innovation management
- Technology & Innovation
- Industrial and Manufacturing Engineering

DIGITAL PLATFORMS AND MULTIMEDIA
- Digital Economy, main attributes and challenges
- Digital environment and social networks
- Digitization
- Big data
- Internet of things

CORPORATE SOCIAL RESPONSIBILITY AND CONSUMER CLAIMS
- Corporate Social Responsibility
- Public Responsibility and Ethics
- Public Relations
- Organizational Behaviour & Theory
- Consumer Behaviour

REGIONAL ECONOMICS, ECONOMIC AND HUMAN GEOGRAPHY
- Regional economic growth
- Entrepreneurship in small and medium-sized enterprises
- Labour economics
- Economic development of regions and international studies
- Economic impact of migration

ECONOMIC SUSTAINABILITY AND ECONOMIC RESILIENCE
- Bio-based economy
- Economic geography
- Economic progress in emerging countries

- Macroeconomic framework of emerging countries
- Corporate finance and governance

INTERNATIONAL RELATIONS AND GLOBALIZATION
- Standards and paradox of international relations
- Impact of economic and social changes on international relations
- Sustainable cooperation in international scale
- Impact of globalization on international relations

TRANSPORT AND LOGISTICS
- Smart city
- Autonomous vehicles
- Supply chain logistics
- Transport economics and management

FINANCIAL MANAGEMENT AND FINANCIAL MARKETS
- Global perspective of financial markets
- Global trends in financial transactions
- Impact of sustainability on corporate performance
- Financial structure and systematic risks of enterprises

MATHEMATICAL MODELLING IN ECONOMICS AND MANAGEMENT
- Risk analysis and modelling in economics and finance
- Financial econometrics
- Longitudinal research
- Structural credit risk modelling

TABLE OF CONTENT

Problems of sustainable development in the global economy: green economy and economic security

Abstract

Research background: Sustainable development is one of the main priorities of the global economy, which is especially important in a geopolitically complex. One of the key points of sustainable development is green economy. Although the application of green technologies has a basis from the perspective of ecology, biology and other earth sciences and has its own economic efficiency, it can create problems in such areas of the economy as food and energy security. In particular, the examples of Ghana and Sri Lanka clearly demonstrate that even quite successful countries can lead to an economic crisis due to the non-competitive introduction of green technologies. Otoh, green technologies make it possible to develop export-oriented import substitution within the framework of proactive industrial policy.
Purpose of the article: The purpose of the research is to analyse the economic policies of several countries and identify the success factors of economic policies aimed at achieving sustainable development.
Methods: Such methods as building a matrix of competitiveness of territories and the Balassa index for analysing the prospects for export orientation are used.
Findings & Value added: Conclusions are drawn that the implementation of green technologies should be based on an adequate economic policy, otherwise the country's economy may not withstand this transition. Using the example of Russia, the article shows how to apply the Balassa index in assessing sectoral prospects for the implementation of an export-oriented industrial policy strategy and how such a strategy allows achieving a high level of food and energy security.

Keywords: *sustainable development; green economy; economic security; industrial policy*

JEL Classification: *Q01; Q18; Q43*

1 Introduction

Sustainable development is one of the main priorities of the global economy, which is especially important to promote in a difficult geopolitical environment. One of the pillars of sustainable development is the "green" economy. The "green" economy is understood as a dynamic process of transforming the economy towards low-carbon development, increasing resource efficiency and the well-being of the population through the use of technologies and innovations that create new jobs and reduce environmental risks in the long term (Zomonova, 2016). Note that in order to achieve its goals, the green economy must be development-oriented: in 2011, the World Bank describes the "green" economy as an economy in which economic growth and environmental responsibility mutually reinforce each other, while at the same time supporting progress in social development (Simpson, 2011). However, over time, the situation begins to change: already in 2016, the World Bank, defining "green" growth, focuses, firstly, on the problem of resource conservation (efficiency in the use of natural resources); secondly, on environmental cleanliness (minimizing environmental pollution) and, in fact, moving away from such postulated sustainable development goals as the elimination of hunger (goal number 2) and affordable and clean energy (goal number 7). Such an interpretation changes our understanding of sustainable development and becomes the basis of the so-called "environmental revolution", when, contrary to data and common sense, ecology is declared a "global trend", and everything that is "not environmentally friendly" is subject to almost immediate destruction. Such "environmental chauvinism" not only makes sustainable development unsustainable, but also leads the economies of countries using this approach to a crisis.

Even though the use of green technologies is justified from the standpoint of ecology, biology and other geosciences and has its own economic efficiency, it can create serious problems in such areas of the economy as food and energy security. Let's take a look at these questions in more detail.

1.1. Green economy and energy security

The core of the introduction of green technologies in the energy sector are renewable energy sources, because ecology and the economy are closely related, and more than ever, this topic is very relevant today, both in the field of economics and in ecology. Every year more and more countries begin to switch to "green" energy. Each country tries to choose the best option available to it. Consider the main types of alternative energy and their contribution to economic activity (Table 1).

Table 1. The main types of renewable energy sources and their characteristics.

Type of energy	Estimated capacity	TW Household use	TW Use problems	Environmental impact
Solar energy	100000	0,3	Not evenly distributed in space and time	Close to acceptable
The energy of the "solar wind"	0,001	no	Virtually absent on the surface of the Earth	no
Tidal energy	1	0,01	Narrow spatial localization	Significantly transforms the landscape
Water energy	3	1	High capital costs during the	Significantly transforms the

			construction phase	landscape, and sometimes the climate
Geothermal springs	30	0,01	Narrow spatial localization	Close to acceptable
Wind energy	2000	0,5	Not evenly distributed in space and time	High maintenance and disposal costs, climate change possible
The energy of earth magnetism	10	no	Technological problems, very high costs during the construction phase	no
Nuclear and thermonuclear power engineering	300	10	High costs during the construction phase	Danger of environmental pollution in case of accidents
Biofuel	1000	30	Drive up global food prices	weak

Source: BP Statistical Review of Global Energy (2019), Alternative energy: prospects for the development of the renewable energy market in Russia (2021)

Today in Europe there are radical changes in this area. The supply of oil, gas and other extracted resources was stopped for political reasons, and the majority of own sources of non-renewable resources were withdrawn from circulation or do not allow meeting all needs. The situation is aggravated by the negative policy of the European Union towards non-renewable energy sources. The transition to such resources is good enough for the environment, but such a drastic transformation (the European Union decided to achieve a fully renewable energy by 2026-2030) has already led to an increase in energy prices (which is contrary to sustainable development goals) and the raw materials needed for its production. Prices for many green energy feedstocks and transport costs continue to rise. From 2020 to March 2022, the price of polysilicon for solar panels increased by 4 times, steel increased by 50%, copper by 70%, aluminium by 2 times, and transportation costs increased by almost 5 times. As a result, the total investment costs in the construction of solar and wind power plants increased by 15–25%. On the face of it, the competitiveness of renewables is enhanced by the much more dramatic increase in the cost of gas and coal. But these sources cannot provide continuous generation during the day and, moreover, provide a constant necessary amount of energy for the operation of factories. Electricity prices in the EU are breaking historical records: wholesale prices in Germany, France, Italy and Spain have increased by more than 6 times compared to the average values of 2016-2020. As Bloomberg postulates in its European Energy Outlook report, the EU is rapidly descending into a deep energy crisis (Elbahrawy, 2022). It cannot be resolved quickly and by market methods, which makes the EU economy less and less efficient. At the same time, theoretically, a replacement for Russian gas for the EU can be found no earlier than within five years, and this will be an extremely expensive alternative without a guarantee of uninterrupted supplies.

It looks like the European Union has followed Ghana's path in abandoning economic efficiency. Ghana is a newly prosperous state in Africa, a fast-growing economy, and a net exporter of electricity in 2014. In 2015, the World Bank adopted a program for its energy transformation and economic efficiency (supported by grants from the World Bank and various non-profit organizations), which was aimed at the dominance of green energy. As a

result, since 2021, there have been constant power outages in the country in the regions, residents are left without electricity and even water (after all, electric pumps are used).

1.2. Green economy and food security

"As the world is moving into a sustainable era, achieving zero hunger has become one of the top three Sustainable Development Goals, applying a considerable amount of pressure on the agri-food systems to make decisions contemplating the sustainability dimensions," writes Professor Chethana Kumari Chandrasiri et al. (Chandrasiri et al., 2022). However, in fact, this, unfortunately, is not true, which is clearly illustrated by the example of Sri Lanka. "Environmental chauvinism" leads to huge problems in the field of food security. Thus, in 2016, Joseph Stiglitz called on the government of Sri Lanka to switch to "highly productive organic farming" to reduce the differentiation of society (Stiglitz, 2016). In 2019, a new president, Gotabhaya Rajapaksa, came to power in Sri Lanka, who was a supporter of organic farming and banned the purchase of fertilizers starting in 2020 (under the pretext of budget cuts due to the pandemic and the fight for the environment). Rajapaksa wanted to turn Sri Lanka into the world's first country with agriculture without fertilizers and pesticides, with completely organic agriculture. As a result, in 2 years he managed to bring a prosperous country to default, plunge the country into an energy crisis (no money to buy fuel), turn a food exporter into an importer and cause the largest riots in the history of the country. (Mammadov, 2022)

It should be noted that there is no consensus in the scientific community with the basic climate models (Goulet Coulombe and Göbel, 2021) and tools used to green the economy. It seems that the attempt to apply modern technologies of the green economy and the attempt to present "non-green" technologies as economically inefficient - climate finance (Fang et al., 2021) - is grossly disrupting the movement towards sustainable development. What can be done here? It is possible to study the experience of Russia, which implements a proactive industrial policy (Kirillovskaya et al., 2016) and managed to significantly increase the efficiency of the economy.

1.3. Ways to solve the problem of food security: export-oriented import substitution (case of Russia)

In the context of the ongoing sanctions confrontation between Russia and Western countries led by the United States, as well as the consequences of the COVID-19 coronavirus pandemic, pushing the world towards a global economic crisis, the issue of increasing the country's competitiveness in the international arena and ensuring its economic security does not lose its relevance. Thanks to the policy of import substitution since 2014 (the beginning of the sanctions confrontation), several Russian industries have not only overcome their critical dependence on imports but have also built up a significant export potential.

As for the dynamics of exports, it can be noted that for most commodity groups, the share of the Russian Federation in world exports, albeit slightly, has increased. However, product groups that account for more than 1% of world exports still account for only 1/3 of the total. At the same time, high positions (more than 5%) remained in the export of timber (6.12% against 5.6% in 2014) and cereals (7.84% against 5.89% in 2014). At the same time, fertilizers (12.57%), mineral fuels and oils (9.4%), as well as nickel and products from it (13.28%) consistently demonstrate the highest export rates (more than 9%).

Based on this, it is possible to single out commodity groups that have the greatest export potential (see Table 2).

Table 2. Groups of goods with the greatest export potential (% of global exports)

		2014	**2015**	**2016**	**2017**	**2018**	**2019**	**2020**
10	Cereals	5,89%	5,43%	5,81%	7,21%	9,30%	7,50%	7,84%
27	Mineral fuels, mineral oils	11,40 %	11,95 %	9,10%	10,75 %	9,49%	10,71 %	9,40%
31	Fertilizers	13,78 %	14,19 %	13,31 %	14,13 %	13,96 %	14,68 %	12,57 %
44	Wood and products;	5,61%	5,08%	5,14%	5,84%	6,08%	6,33%	6,12%
72	Cast iron and steel	4,98%	4,65%	4,68%	5,04%	5,52%	4,92%	4,92%
75	Nickel and products	13,27 %	10,57 %	10,89 %	10,41 %	10,19 %	10,79 %	13,28 %
81	Other metals; cermet; products	4,40%	4,75%	4,80%	4,32%	4,88%	4,82%	4,94%

Source: author's calculations

However, the progressive development of the domestic economy was noticeably hampered by the spread of the coronavirus infection and the massive sanctions of the collective West. Sanctions, the pandemic and quarantine measures against it caused a significant reduction in the income of a significant part of the population, a sharp decline in domestic demand, and an increase in inflation. Nevertheless, even despite the general decline in foreign trade indicators, the dynamics of exports and imports shows that Russia's potential is by no means exhausted, especially strong increments are given in 2021 and, especially, in 2022, the sale of energy resources and grain gives (in full accordance with the concept sustainable development). In order to show whether this is actually the case and which sectors of the Russian economy are the most promising for the implementation of an export-oriented industrial policy strategy, let us turn to the calculation of one of the most indicative indices in this respect - the Balassa index.

2 Methodology

The Balassa Index (RCA) is a calculated value of any country's revealed comparative advantage in producing and exporting a full range of products in a given year. Country A is said to have a revealed comparative advantage in a given product i when the ratio of exports of product i to total exports of all commodities exceeds that of the world as a whole.

$$RCA_{Ai} = \frac{\frac{X_{Ai}}{\sum_{j\in P} X_{Aj}}}{\frac{X_{wi}}{\sum_{j\in P} X_{wj}}} \geq 1 \tag{1}$$

Where:
P – the set of all products (with $i \in P$),
X_{Ai} – export of product by i country A,
X_{wi} – global product export i,
$\sum_{j\in P} X_{Aj}$ – total exports of country A (of all products j in P),
$\sum_{j\in P} X_{wj}$ – total world exports (of all products j in P).

When a country has a revealed comparative advantage for a given product (RCA≥1), it is assumed to be a competitive producer and exporter of that product compared to a country that produces and exports that good at or below the world average. A country with a revealed comparative advantage in product i is considered to have a strong export position in that product. The higher a country's RCA value for product i, the higher its export power for product i.

3 Results

According to UNCTAD, industries and products with a revealed comparative advantage (RCA≥1) can be classified (see Table 3):

- food products, among which various grain crops (first of all, wheat and barley), as well as fish and seafood have the greatest export potential;
- non-food raw materials (except for fuel), primarily nickel ores and concentrates, whose export potential has increased by 5.7 times over the years of the sanctions confrontation (!), as well as timber and primary wood products (note the growth in exports of finished wood products under a slight decrease in roundwood exports, which indicates an increase in the value added of exported products); in addition, crude fertilizers and sulphur products have a tangible competitive advantage;
- mineral fuels, in the field of export of which Russia's competitive advantages have significantly increased (despite the decrease in natural gas supplies). In particular, one can note the high potential for the export of petroleum oils and coal, as well as peat, coke and residual oil products;
- animal and vegetable oils, whose comparative competitive advantage increased from 2.18435 to 3.98205 during the period under review;
- chemical products, where fertilizers are the absolute leader;
- processed products classified primarily by material, primarily iron or steel ingots, nickel, cast iron and sponge iron, silver and platinum, as well as veneer, plywood and other wood products;
- machinery and transport equipment (although the growth of competitive advantages compared to 2014 can only be noted in terms of exports of railway vehicles and related equipment).

Table 3. Calculation of the Balassa Index (RCA): Export Groups with the Largest Comparative Advantage

	2014	**2015**	**2016**	**2017**	**2018**	**2019**
Wheat and meslin	4,27287	4,88233	6,09043	6,887619	8,797597	6,99467
Barley, unground	3,77664	5,76215	3,59545	5,202693	5,742415	4,68420

Thus, over the years of sanctions opposition, the Russian Federation has built up a significant export potential in such industries as the agro-industrial complex, metallurgy, the chemical industry and the timber industry, as well as mechanical engineering. Exports of grains (wheat, barley and corn), fertilizers, refined petroleum products, wood products and metal products have particular comparative advantages. Based on the latest data on the growth leaders in exports of industrial and agro-industrial products of the Russian Federation (see Table 4), it is safe to say that these comparative advantages will continue even despite the global economic downturn caused by the coronavirus pandemic.

Table 4. Growth leaders in 2020

	Growth, million USD	Export, million dollars	Growth rate
Mechanical engineering			
Specialized vessels	315	324	3580%
Passenger cars	88	194	82%

Nevertheless, the Russian Federation categorically cannot stop there, because. agricultural and raw material specialization without the progressive development of first capital-intensive, and then science-intensive industries will not lead to sustainable economic growth in the long term.

4 Discussion

This model can be applied to analyse various situations related to economic policy. At the same time, there are certain limitations associated with both the analysis of sustainable development and the features of the model itself.

First, statistics reflect the state of the economy in past periods. Therefore, if there has been a qualitative change in the economic environment or the introduction of fundamentally new instruments of economic policy, then in the short term, an incorrect result may be obtained.

Second, some of the sustainable development goals may be achieved with a long-time lag, and negative results may reflect "exogenous heterogeneity in the timing and scale of benefits", as noted by Gollin et al. (2021), rather than be the result of a fundamental restructuring of the entire economy.

Thirdly, food and energy security are critical policy areas, which give rise to often untimely and populist actions (as noted, for example, by Rodrik (2018), Harstad (2020)), exacerbated by fake news (Massey et al., 2018) and often leads to research bias, as emphasized by Rubin and Rubin (2021).

Fourth, despite the high level of development of the topic of climate change, a number of the models used are oversimplified, as emphasized by Philippe Goulet Coulombe and Maximilian Göbel (Goulet Coulombe and Göbel, 2021), which clearly demonstrate the

errors of the models used (Stips et al., 2016). Therefore, the original results may not be entirely true.

Fifth, regulation of the greenhouse gas market is very difficult: as early as 2019, Severin Borenstein, James Bushnell, Frank A. Wolak, and Matthew Zaragoza-Watkins (Borenstein et al., 2019) warned that the market price of greenhouse gas allowances will not be determined by market methods, but by an administrative price floor or price cap, with "a unilateral carbon tax resulting in a loss of welfare" even for highly developed countries (Baylis et al., 2012).

Sixth, the success of the export-oriented development model when applying the import substitution policy requires the implementation of a proactive industrial policy that is closely related to achieving critical economic security parameters and taking into account social risks (Kirillovskaya, et al., 2016; Kliestik and Dengov, 2015). However, this factor is often not taken into account when analysing the situation.

5 Conclusion

To achieve the goals of sustainable development, it is necessary to focus on the evolutionary nature of the ongoing changes. It is important to take into account that the replacement of obsolete and less environmentally efficient tools with others is possible only when innovative tools become economically profitable and make it possible to support social production and a comfortable existence of citizens. Attempts to politicize the problem and "cancel" non-renewable energy sources to please voters or global financial institutions are doomed to failure.

As a result, it can be argued that in order to achieve economic growth, it is impossible to focus solely on import substitution, abandoning efficient technologies in the energy and agriculture sectors. it is usually limited by the capacity or purchasing power of the domestic market, and also reduces the competitiveness of enterprises protected by protectionist support measures. Further development can only be ensured by integrating into global production chains. At the same time, the training of highly qualified personnel, support for fundamental R&D and further stimulation of proactive export-oriented businesses seem to be of fundamental importance.

Using the Balassa index, it is possible to identify the key success factors of styrene and make the most competitive industries the basis for the application of proactive industrial policy and export-oriented import substitution.

In addition, in addition to the already existing export promotion tools, it is worth improving the system of state strategic planning in terms of developing short-, medium- and long-term plans and development scenarios not only for the economy in general, but also for foreign economic activity in particular, based on the successful experience of China and countries "Asian tigers".

The Year 2022: The Economic Policy In The New Reality

Armen Altunyan[1], and *Tatiana* Kotcofana[1,*]

[1] Saint-Petersburg State University, Faculty of Economics, Department of Economics and Economical Policy, Universitetskaya emb., 7-9, 199034, Saint-Petersburg, Russia

Abstract

Research background: The modern model of the economy, with its glaring inequalities in the distribution of income and wealth, a bet on the development of the financial sector, a high level of consumption with a low level of production, has put society in the face of fundamental challenges that require the development of a model adequate to the new reality. The current world order in the context of financial turmoil is particularly painful for countries whose financial markets are among the developing ones.

Purpose of the article: The main purpose of this article is to analyse the problems faced by developing countries (for example, Russia) in the modern economic model, and ways to solve these problems.

Methods: To conduct the study, we used official statistics data, the analysis of which allowed us to determine the degree of mutual influence of key parameters of economic development.

Findings & Value added: Determining the directions of implementation of the new economic policy, it seems important to build a two-circuit model of economic management based on the compatibility of the planned system and private interest. Such a model should combine two components. The first component is the mobilization, administrative and command economy, aimed at ensuring its stability in the face of external challenges and priority support for strategic industries. The second component is a market economy, where private entrepreneurship would deal with the problems of saturation of the domestic market due to import substitution.

Keywords: *economy policy; model of the economy; finance system; emerging markets*

1 Introduction

The emerging geopolitical situation and the sanctions of Western countries have exacerbated the risks and contradictions in economic policy that have been accumulating in

---

[*] Corresponding author: t.kotsofana@spbu.ru

the Russian economy in recent decades. We are faced with fundamental challenges that require the development of a model which is adequate to the new reality.

For almost three decades, the Russian economy has struggled to become an equal part of the global economic community, by getting involved as much as possible in the processes of globalization. Meanwhile, despite the ambiguity of the definition of the category "globalization" in modern economic theory (Nový, 2015), most authors agree that it not only carries a positive potential for the world community, but also increases the risks and threats to its development (Šoltes & Štofko, 2015). Globalization processes contribute to the increasing of the contradictions in the development of the world community (Tokárová, 2015), the growth of the interdependence of national economies (Kramárová & Valášková, 2015), and their increasing dependence on a relatively small number of transnational corporations (Harumová, 2015). One of the most important features of these processes has become the widespread financialization of the economy, which enslaves society and subordinates the entire economy to its logic. As a result, the financial sector no longer performs the function of optimal allocation of capitals and risks and contributes to the further development of "casino finance". Due to these circumstances, the economy stops to play its role and contribute to social welfare (Bernards, 2019, Bresser-Pereira, 2019). According to a study (Van Velthoven et al., 2019), income inequality caused by finance (financial development, financial liberalization and banking crises) is associated with more income redistribution than inequality caused by other factors. Meanwhile, the growing social bundle of society and economic inequality are considered by many leading economists as one of the key global threats not only to economic development, but also to the whole world community (Nordhaus & Romer, 2019, Piketty T. et al., 2019, Stiglitz J., 2015, Sen A., 2015).

In this way, the Western model of economic development with a stake on the development of the financial sector, a high level of consumption with a low level of production has turned the economy of the golden billion into a destabilizing factor in the world economy. In May-June 2020, the President of the World Economic Forum, Klaus Schwab, proclaimed the "Great Reset", the main goal of which is the transition from current capitalism to the so-called inclusive supranational world capitalism, under which a new slave-owning system is hidden. (Katasonov, 2021)

Until recently, Russia was involved to the maximum in the described processes and acted as a vivid example of how the dominance of the "golden billion" countries and their largest companies damages the national interests of less developed countries.

2 Research methods

The methodological basis of the research is the dialectical materialistic and concrete historical method. At the same time, the dialectical-materialistic approach is the initial principle of research. As applied to this study, this means that, on the one hand, the dialectical method allows to know the essence and causes of the processes considered in the most adequate reflection of their dynamic integrity, on the other hand, any theoretical research should be supported by historical practice and statistical data. In this regard the empirical basis of the analysis is statistical materials and specific economic and statistical studies.

3 Results and Discussions

Modern economy, with its blatant inequalities in the distribution of income and wealth, has gone down the wrong path. While some take away value and pump wealth out of national economies, others act as resource providers and wealth creators, but do not receive anything

from this wealth. The current development model, which encourages "rent seekers" rather than true "wealth creators", stimulates the desire to generate income not by producing something new, but by imposing a premium on top of the competitive environment and undermining competition. Rent-oriented activity is aimed at taking value from creators. The financial sector has enormously diversified, and its total volume has increased significantly. This is especially true for such segment as asset management, which has become one of the fundamental characteristics of modern capitalism. Financial markets simply distribute income generated by activities in other areas and add nothing to those incomes. There is no way to change this, financial regulation must be used to help steer the financial sector towards the real economy, encouraging long-term investment through a tax on financial transactions.

Around 1970, the system of national accounts, which gives picture of one or the other economy, began to include the financial sector in the calculation of GDP as the total value of goods and services produced in the economy. Taken together, these changes have increased the influence of the financial sector over the real economy. So, the contribution of the financial sector to the economy in the UK is 7.2% of GDP, and in the US, it is 7.3%. Today problem is not simply in the size of the financial sector and its superiority over the non-financial sector, but its impact on large segments of the economy that have become financialized. The financial sector acts as a rentier - a value miner which is interested in short-term income. «For large banks and speculative funds, the satisfaction of private interests is increasingly at odds with the common good and interests of the economy» (Rampini and Viswanathan, 2018).

Starting out from 2008, the global financial system solved any problems by issuing additional money and increasing public debt, which did not solve the accumulated structural problems, but created new ones. Measures to support the global economy during the pandemic have exacerbated the situation. The Fed, by having printed an additional 7 trillion dollars, deprived itself of the possibility in the future of the usual tools for dealing with the next crisis. The aggravation of the geopolitical situation and its consequences associated with rising food and energy prices gave rise to a new global crisis comparable to the scale of stagflation in the 1980s.

The Fed's balance has grown from almost $1 trillion to $9 trillion from 2008 to 2022. The same trend was observed in the economies of Europe, Japan, Canada, Australia, Great Britain and Switzerland. As a result, the total balances of all the listed Central Banks grew from $4.5 trillion to $29 trillion by the beginning of 2022. Global inflation began to gain momentum since 2020. In the structure of the inflation index, energy and food are the most rising in price groups of goods.

According to the IMF, at the end of 2021, US GDP amounted to 23.0 trillion. dollars, equal to a quarter of the world, and the volume of US debt has already exceeded 30 trillion dollars, and this is clearly not the limit. The debts of developed countries such as the USA, Italy, France, Japan exceeded 100% of GDP. They can be served only at zero rates. Rising inflation in these countries, approaching the double-digit mark, will increase the price of new borrowing and lead to a tightening of monetary policy, the development of a debt crisis, which is fraught with the potential for a global destruction of the world economy with a slide into a financial disaster.

In the face of financial turmoil, the current world order hits especially hard countries whose financial markets are among the developing ones. Minor disturbances in the world markets lead to capital escape to the "quiet" dollar haven, which destroys their currency systems and causes inflation. We observed such a scenario in the context of global crises in 1998., 2008., when a massive outflow of capital from Russia led to a panic in the currency и and stock exchanges, increased ruble inflation, suppressed real investment, which led to a drop in real incomes of the population and an increase of unemployment.

Thirty years of integration into the global financial system, which can rightfully be called the offshorization of the Russian economy, is over. The Russian Ministry of Finance was proud of the share of non-residents in the OFZ market, borrowing rubles at double-digit rates, while giving the euros and dollars earned by the country at 2-3% growth. A high key rate made the bond market attractive and gave a competitive advantage to foreign investors who could raise cheap loans at home. Such model was destroying the domestic industry, which did not have the same available cheap financing. The most popular type of foreign business in Russia was the "carry trade" operation when they were engaged in loans at 2% in their homeland and issued to the Russian Ministry of Finance at 10%. "Structural" and "institutional" reforms were carried out, because of which 20% of the shares of Rosneft were owned by BP, 40% of the shares of Sberbank - by non-residents, control over a dozen strategic industrial and infrastructure enterprises - by Western countries, creating threats to economic security with what we are facing in today's conditions.

However, after Russia's exit from the global financial web, our economic system and the whole economy are being reformatted. Let's decide with the changes and priorities of economic policy in the new conditions.

Firstly, the outflow of capital from the country has stopped, which gives hope that these funds will now be used within our economy. The only important macroeconomic parameter in such conditions will be the size of the trade balance. If earlier we tried to have a trade balance surplus, a significant part of which either turned into an outflow of capital or accumulated into reserves that ensure the conditions for the stability of our economy, now in the new conditions the question arises of how to manage these surpluses. It no longer makes sense to increase the export of energy resources, receiving the currencies of unfriendly countries for them. The domestic economy was annually deprived of investments from 100 billion dollars due to the formation of foreign exchange reserves, the replenishment of the NWF and the export of capital. It is fundamentally important, while supplying our energy carriers to these countries, to receive a return flow maybe in a smaller volume, primarily of goods, not money, what will help to achieve a balance of our ability to monetize exports for the required volume of imports. In March 2022, exports exceeded imports by two and a half times. Therefore, the ruble is strengthening against the dollar and the euro. The inflow of foreign currency to the domestic market increases because of the introduction of the mandatory sale of 80% of export foreign exchange earnings in rubles, but as the ruble strengthens, 50%. The freezing of the Central Bank's reserves in the currencies of unfriendly countries in the amount of more than 300 billion dollars made it necessary to switch to paying for 100% of Russian gas exports in rubles, which will stimulate the trade partners of the Russian Federation to accumulate ruble reserves. The ruble ceases to be a currency of exclusively domestic consumption since it can be used to buy something in global economic activity. There is a vital need to develop a new monetary system with the ruble pegged to real monetary assets or to a basket of export goods that have a currency value. Russia accounts about 40% of the world's stocks of goods that have both commodity and monetary properties. It is impossible to underestimate Russia, which occupies 25% of the world energy raw materials market, provides about 15% of world grain exports, has strong positions in the metals, uranium, etc. Based on these goods, index of multi-commodity price stability is formed, which allows to create commodity-currency reserves as a replacement or supplement to existing gold and foreign exchange reserves.

The development of a national currency strategy within the framework of the ideas of the Breton Woods system of the new version, which involves pegging national currencies to real assets, is a condition for ensuring one's own independence as a global economic unit, and not a colony of the world dollar system.

As a result of the economic measures taken by the authorities, citizens' confidence in the ruble has grown and the volume of deposits in Russian banks now stands at about 30 trillion rubles.

Secondly, in the conditions of the new reality, the size of the budget deficit should become the main parameter. Before the well-known events, the most important postulate of budget policy was a balanced budget. Additional oil and gas revenues, within the framework of the budget rule, were accumulated in special sovereign funds, being converted into reserve currencies of unfriendly countries. In the current conditions, such construction is no longer acceptable and there is a need to move to deficit budget financing. At the same time, the deficit should play the role of a development budget aimed at stimulating the restructuring of the economy. The size of the deficit should be regulated considering the possibilities of domestic, market, non-equity financing. Here we have a reserve - this is a low amount of public debt (external and internal) of just over 20% of GDP, where 13% is domestic).

Thirdly, among the most important measures, must be noted the transition from the financial and economic justification of investment measures to the socio-economic one, the key parameter of the effectiveness of which can be employment and income growth. At the end of 2021, commercial banks earned a record profit for the entire post-Soviet period (see Table 1) - about 2.4 trillion rubles, more than the net financial result of agriculture, construction and transport combined. Like any intermediaries, banks do not create added value. By attracting deposits and issuing loans, banks are engaged in the purchase and sale of money and appropriate for their services a part of the GDP created by the real sector of the economy. The sources of super profits of banks were the working capital of enterprises and the funds withdrawn from citizens through loans. In the conditions of the most acute geopolitical crisis, the formation of available financial resources for import substitution becomes a matter of national security.

The urgent need for changes in the financial sector has led to the fact that over the past three months, the Russian financial authorities have done more to develop the country's domestic financial sector than in a decade. The most important thing that was done was that the Russian financial authorities had to block the channels of capital outflow from Russia and disconnect the country from the external financial circuit.

Table 1. Key indicators of the Russian banking sector for 2014-2021.

Year \ Indicator	2014	2015	2016	2017	2018	2019	2020	2021
Bank assets to GDP, %	108,7	99,7	93,0	92,5	90,8	88,4	96,9	92,1
The share of loans to the economy in GDP, %	57,2	52,8	47,7	45,6	46,5	47,0	60,6	58,8
The share of loans to the economy in the assets of banks, %	52,6	52,9	51,3	49,1	51,3	53,2	62,5	63,8
The profit of the banking sector in billion rubles	589,1	191,9	929,6	789,6	1344,8	2036,0	1909,7	2363,0

Source: Bulletin of Banking Statistics 2015,2016,2017,2018,2019,2020,2021, 2022.

Fourthly, the final goal of the medium–term economic policy may be the structural and technological restructuring of the Russian economy based on the domestic market and exit by 2025, at a steady pace of sovereign economic growth, building a self-sufficient economy capable of providing itself with 90% of everything necessary and only 10% of imports in relation to GDP. Before the well-known events, this share ranged from 20 to 30%.

Since the beginning of the military special operation, the budget surplus amounted to more than a trillion rubles, the foreign trade balance surplus was $190 billion, the exchange rate of the ruble against the dollar strengthened to 60 rubles against the backdrop of growing payments for gas under the scheme proposed by Russia, the global food market is increasingly degree depends on ours. But these successes should not lead to euphoria and put off for the future - the restoration of a full-fledged industrial system with production chains deeply integrated into our economy. Now we do not know how to produce complex special equipment for road construction, we almost do not have our own high-quality motor fuel, we do not grow durum wheat, we do not produce silk or wool, we do not have our own fine chemistry in order to make high-quality medicines and cosmetics, and we don't even produce nails. Medium business in Russia is waiting for sectoral programs of consistent import substitution.

At first glance, it may seem that huge funds are needed. But if we convert the reserves we lost into rubles and divide them by the years that we accumulated them, we will find out that every year we have taken more out of the economy than was necessary for consistent import substitution. Now we have lost most of the foreign exchange reserves, but at the same time did not feel the strong consequences. So, it is not about the money. It is just that in some minds of the Russian elite there is a consciousness that sanctions will be weakened, and everything will return to its former life, or there is a desire to replace one import with another.

The cost of existing demand in the context of recovery instead of importing production chains is estimated by analysts at 18–20 trillion rubles, while investments in the creation of such new volume of value should be approximately 30% of GDP annually, which will ensure economic growth at a rate of 7–9% per year and the growth of the well-being of the majority of the population in Russia. We have the potential to achieve such sustainable economic growth. The gap between gross savings and gross savings is up to 10% of GDP (see Table 2). This result was due, among other things, to the insufficiently efficient work of banks in investment lending to the economy. A high propensity to save on the part of the population gives a negative effect to the investment multiplier. Kaigorodova et al. (2018) showed in their study (2018) that in Russia there is a tendency to increase the amount of money left outside the sphere of consumption or investment. This situation has developed in our country due to the low level of trust on the part of most people in commercial and government structures, many people are not sure about their future and prefer to save money "for a rainy day."

Russia, with its low standards and structure of household consumption and underfunding of investment projects, is still far from meeting its basic needs: the level of housing provision and provision of cars is three to four times lower than in economically developed countries, the provision of durable goods is significantly lower, the lag in the level of development of transport infrastructure is multiplier, the gap in the consumption of some essential foodstuffs remains significant (Kotsofana, 2007). In this regard, the idea of effective management of aggregate demand is especially important since long-term economic growth is impossible without its expansion and increasing of investment.

In conditions of investment hunger, with falling consumer demand, the real sector can accumulate money emission without pressure on the foreign exchange and consumer markets. And it is right time for the Bank of Russia to follow the path of most developed countries, where governments and central banks provide systematic support to their economies through the form of financial injections and the provision of government guarantees. (Ruščáková, 2015). At the same time, they see deflation rather than inflation as the main threat to the stability of their economies (Jarý, 2015). And this is completely justified, since an important parameter for the economy is not inflation, but real interest rates for the non-financial sector and the volume of lending to the non-financial sector

(Domashcenko, 2016), which grows in proportion to the money supply. There are studies proving that the correlation between inflation and economic growth is not significant, especially in the long run (Bhaduri, 2015). As for the dependence between the growth rate of the money supply and the rate of consumer inflation, it should be noted here that the growth of the money supply, on the contrary, leads to a decrease in consumer inflation (Altunyan, 2015). And here we can agree with Bresser-Pereira (2020) in fact, that «Money is an endogenous variable that does not cause but just validates a going inflation».

Table 2. GDP, savings, investments in 2014-2021.

	2014	2015	2016	2017	2018	2019	2020	2021
GDP in billion rubles	79030	83087	85616	91843	103861	109241	107390	131015
Gross savings as % of GDP	30,2	30,5	28,2	28,9	31,9	30,5	29,8	32,0
Gross accumulation as % of GDP	22,4	22,1	23,1	23,8	21,9	22,7	23,9	22,4
Gross fixed capital accumulation as % of GDP	21,4	20,6	21,9	22,0	20,6	21,1	21,7	19,8
Investments in fixed assets as % of GDP	17,6	16,7	17,2	17,4	17,1	17,6	18,9	17,5
Investments in fixed assets in % compared to the previous year	3,3	-0,1	6,1	8,7	10,9	8,7	5,0	13,0
The degree of depreciation of fixed assets in % at the end of the year	49,4	47,7	48,1	47,3	46,6	37,8	39,0	39,0

4 Conclusion

In this way, defining the directions for the implementation of the new economic policy, it seems important to build a two-loop model of economic management based on the compatibility of the planned system and private interests. On the one hand, the mobilization, administrative-command economy, aimed at ensuring its stability in the face of external challenges and priority support for strategic industries. On the other hand, the market, where private business would deal with the problems of saturating the domestic market through import substitution.

Abstract

Research background: Smart technologies and Internet are an integral part of every day life making it more convenient and transforming the way employees work. While it allows employees to work when and where they want, it increases the risk of employees working later in the evenings of letting the work into weekends.

Purpose of the article: The purpose of the paper is to identify the effectiveness of work in the evening and on weekends and propose sustainable development solutions. The aim of this research is to analyse the impact of work in the evening or on weekends on productivity per capita, life satisfaction and happiness in countries of Eurozone.

Methods: Data were collected from Eurostat database 2017-2021. Correlation analysis and descriptive statistical methods are used to analyse the nature of association between the variables.

Findings & Value added: Working in the evening and on weekends is beneficial neither for the economy nor for well being of employees in Eurozone. Nevertheless, work on Sunday has positive impact on life satisfaction, however it decreases the feeling of happiness what can reflect on employee productivity during the week.

Keywords: *work in the evening; work on weekend; life satisfaction; happiness; four days workweek*

JEL Classification: *J8; J81; M16; M54*

1 Introduction

Human progress is very closely linked to the development of technology and intellectual revolutions. This phenomenon is perceived as a fact when the speed of growth and development overtakes the very needs of people. On the other hand, the satisfaction curve is influenced by factors that directly affect the productivity and efficiency of processes. In principle, there is an equation, the better people are, the more they expect in their favor. With the goals of very rapid growth, a turning point is occurring, which in the past was

---

focused on sustainability - primarily human resources. In these cases, a social system was developed, employee protection was developed, working hours were shortened, working conditions were improved, or various alternatives and flexible forms of work organizations were introduced.

The limitation of resources and lack of inputs is beginning to show in some industries, which forces us to think about the very setting of processes and production. In recent years, general progress has focused on the concepts of ecology and sustainable growth. Many problems in the form of rapid global warming or the ongoing energy crisis are the result of disproportionate and uncontrolled development at the expense of nature.

Not only GDP growth and positive numbers in graphs, but real benefits and satisfaction on the part of organizations and employees can contribute to permanent development.

1.1 Effectiveness of evening work and work on weekends

Continuous operations or production (on weekends and during the night) is economically beneficial for organizations, therefore considered as an advantage, but is this still valid?

The price of inputs and the cost of continuous operations or production are lower than the price for the product itself. Another positive effect of this shift setting is the need to hire more employees what results in a reduction of unemployment or is able to create opportunities for other types of employees (Heyes and Tomlinson, 2021).

It is true that manufacturing and industrial countries have more evening shifts and weekend work in an effort to continuously produce and meet production plans, especially in Central and Eastern Europe (Trif et al., 2021). In services, the main point of weekend and night hours is to provide continuous services or availability at a time when customers expect it and have the opportunity to use their free time. Many services aim at the weekend or night work, where this form of work cannot be avoided. Therefore, it is still true that many employees choose this type of employment (an atypical work schedule) as a solution to their situation when other circumstances prevent them from working in a standard employment relationship. Hence, employees can possibly earn extra money and use the "regular day" for other activities. Productivity of employees, however, faces its limits and an unstable regime has adverse effects in the long term (Pereira et al., 2021).

On the other hand, at low input and energy prices continuous operations and production is the most reasonable solution. The pressure to save, in addition to economic, ecological solutions, has been intensifying in the Eurozone in recent years (Kyriakidis, 2022). The goal of sustainability and the circular economy is to approach models that have an impact on production and services (Riforgiate and Kramer, 2021) that we do not inherently need.

Currently, the rising price of energy is becoming a more significant factor, when organizations begin to re-evaluate their activities in order to achieve maximum efficiency. Many organizations have decided to adapt flexible forms precisely according to the performance of the economy and their objectives.

The impact of setting working hours for employees has an impact on their overall performance, job satisfaction and happiness. A long-term setting can have an impact on health, so it is advisable to have a clear separation of the workweek and the weekend (Ginoux et al., 2021). To be effective means to perform all tasks that have been set without negative effects. Employees prefer flex time, which is limited to weekends and free time when they can relax, but also have space to complete all tasks (Demsky et al., 2021).

Weekend work and night work have their advantages and disadvantages. Due to the influence of ongoing macroeconomic changes in this research, we focused on their impact on the economy and on satisfaction and happiness in the individual countries of the Eurozone.

2 Methods

The purpose of the paper was to identify the effectiveness of work in the evening and on weekends and propose sustainable development solutions. The aim of this research was to analyse the impact of work in the evening or on weekends on productivity per capita, life satisfaction and happiness in countries of Eurozone.

The Eurozone is considered the highest form of integration, cooperation, unity and maturity. Based on the same currency from the point of view of the EU, it helps to recalculate all numbers more easily without losing the conversion rate.

2.1 Data

Data were collected from Eurostat database 2017-2021 for 19 countries in Eurozone. For research purposes, ISO 3166-1 Alpha 2 country codes were used to represent the studied countries in figures and tables.

Table 1. ISO 3166-1 Alpha 2 country codes Eurozone

Belgium	Germany	Estonia	Ireland	Greece	Spain	France	Italy	Cyprus	Latvia	Lithuania	Luxembourg	Malta	Netherlands	Austria	Portugal	Slovenia	Slovakia	Finland
BE	DE	EE	IE	GR	ES	FR	IT	CY	LV	LT	LU	MT	NL	AT	PT	SI	SK	FI

Source: https://www.iban.com/country-codes

Overall work in the evening (Eurostat, 2022a) in Eurozone was decreasing during the studied years (from 16.7% - 13.7%). However, slight increase was recorded in 2021 in Belgium, Estonia, Greece, Spain, France, Luxembourg, Portugal and Finland what could be the result of the pandemic and work from home safety measure. Work from home during the pandemic offered employees not only place but also time flexibility. The highest rates (more than 30%) of evening work during the studied period were in Greece.

Largely, work on Saturday (Eurostat, 2022b) had the highest rates in Eurozone. Between 2017 and 2019 the rates were around 28%. In 2020 and 2021 the work on Saturday decreased to approximately 24%. Majority (approximately 40%) of people working on Saturday were in Greece.

Work on Sunday (Eurostat, 2022c) in Eurozone was stable (about 15%) between 2017-2019 and slightly decreased to 12.6% in 2020-2021. Since 2017 the highest rates (approximately 20%) were reported in Netherlands that decreased to 10% in 2021.

GDP per capita as the macroeconomic indicator capturing the national economic activity was slightly increasing since 2017, but decreased in 2020 (Eurostat, 2022d). In 2021 the values were increasing to the pre-pandemic years. On average, Luxembourg, Ireland and Netherlands reported the highest economic outcomes during the studied period

Data for life satisfaction (Eurostat, 2022e) were available only for year 2018. The highest reported life satisfaction (approximately 8%) was in Ireland, Austria and Finland. Data from Greece, Latvia, Lithuania and Portugal showcased the lowest life satisfaction (approximately 6%). Life satisfaction in the remaining countries from Eurozone was approximately 7%.

The latest data on the frequency of being happy in the last 4 weeks in Eurozone were from 2018. Happiness was measured on a scale from always – most of the time –

sometimes – rarely – never (Eurostat, 2022f). Spain had the highest rates of people being always happy (almost 30%). More than 50% of people living in Belgium, Germany, Ireland, France, Luxembourg, Malta, Netherlands, Austria and Finland were happy most of the time. More than 30% of people who reported being happy sometimes in the last 4 weeks were in Estonia, Greece, Italy, Cyprus, Latvia, Lithuania and Slovenia. More than 10% of people in Estonia, Greece, Cyprus, Latvia, Lithuania and Portugal felt rarely happy. Countries with the least happiness rates in 2018 were Latvia and Greece. Almost 7% of people in Latvia and more than 5% in Greece never felt happy in the last 4 weeks.

2.2 Data Analysis

Correlation analysis and descriptive statistical methods were used to analyse the nature of association between the variables. Additionally, regression analysis and analysis of variance (ANOVA) were computed. Statistical modelling was used to estimate the relationship between work in the evening or on weekends on productivity (GDP) per capita, life satisfaction and happiness in countries of Eurozone using MS Excel add-in program Analysis ToolPack.

GDP, life satisfaction and happiness as the dependent variables were analysed. Taking GDP Per Capita as an indicator for economic growth, life satisfaction and happiness as an indicator of employee well-being, the studied research question was: *How effective and sustainable is work in the evening or on weekends in Eurozone?* Accordingly, the hypotheses were written:

H_{01}: *Working in the evening has no effect on GDP in Eurozone.*
H_{02}: *Working on Saturday has no effect on GDP in Eurozone.*
H_{03}: *Working on Sunday has no effect on GDP in Eurozone.*
H_{04}: *Working in the evening has no effect on satisfaction and happiness in Eurozone.*
H_{05}: *Working on Saturday has no effect on satisfaction and happiness in Eurozone.*
H_{06}: *Working on Sunday has no effect on satisfaction and happiness in Eurozone.*

3 Results

The most important parameters from the regression analysis, ANOVA and correlation analysis necessary to accept or reject the hypothesis are summarized in Table 2 and Table 3.

3.1 Work in the evening, on weekends and its impact on GDP per capita

Table 2. Work in the evening, on weekends and GDP per capita in Eurozone [2017-2021]

	GDP per capita					
	Parameter	**2017**	**2018**	**2019**	**2020**	**2021**

Source: own elaboration

H_{01}: *Working in the evening has no effect on GDP in Eurozone.*
Based on the correlation coefficient (r) in all studied years it can be concluded that between the work in the evening and GDP is a very weak relation. While from 2017-2020 the correlation was negative, positive correlation can be observed in 2021. Despite the correlation the p-values (p>0.05) do not support a rejection of the null hypothesis (Table 2).

H_{02}: *Working on Saturday has no effect on GDP in Eurozone.*
Work on Saturday and GDP between 2017-2019 are in a very weak positive correlation (r) and negative correlation (r) in years 2020 and 2021. Considering very high p-values in all studied years (p>0.05) the relation is not significant. Hence, data does not support a rejection of the null hypothesis (Table 2).

H_{03}: *Working on Sunday has no effect on GDP in Eurozone.*
Correlation coefficient (r) measuring the relation between work on Sunday and GDP per capita from 2017-2021 suggests a very weak to weak positive relationship between the variables (Table 2). However, according to p-values (p>0.05) the relationship is of no significance and does not support a rejection of the null hypothesis.

3.2 Work in the evening, on weekends and its impact on life satisfaction and happiness

Table 3. Work in the evening, on weekends and its impact on life satisfaction and happiness in Eurozone [2018]

		Life satisfaction	**Happiness**				
			Always	*Most of the time*	*Some-times*	*Rarely*	*Never*

Source: own elaboration

H_{04}: *Working in the evening has no effect on satisfaction and happiness in Eurozone.*
Work in the evening is in a very weak negative correlation (r) with life satisfaction and happiness experienced sometimes or rarely. Very weak positive correlation (r) can be observed between work in the evenings and happiness experienced always, most of the time

or never. However, since the p-values are very high (p>0.05), the relation is not significant. The data does not support a rejection of the null hypothesis (Table 3).

H05: Working on Saturday has no effect on satisfaction and happiness in Eurozone.
As per the results, work on Saturday is in a very weak negative correlation with the feeling of happiness experienced sometimes, rarely or never and in a weak positive correlation with life satisfaction and feeling of happiness experienced always and most of the time. Due to high p-values (p>0.05) the relation is not significant and does not support a rejection of the null hypothesis (Table 3).

H06: Working on Sunday has no effect on satisfaction and happiness in Eurozone.
Work on Sunday is in a positive correlation with life satisfaction and in a negative correlation with rare happiness. Both relations are significant (p<0.05). Therefore, the data partially support a rejection of the null hypothesis. Other studied outcomes are in a positive and negative correlation, but the relationship is not significant (p>0.05) (Table 3).
Figure 1. Work on Sunday and life satisfaction in Eurozone

Source: own elaboration

Work on Sunday is in a positive correlation with life satisfaction (F = 5.280, df = 18, r = 0.487, p < 0.05, t = 2.298) (Table 3). With increasing work on Sunday, life satisfaction increases (Figure 1).
Figure 2. Work on Sunday and rare happiness in Eurozone

Source: own elaboration

However the relationship is in a negative correlation with rare happiness ($F = 4.983$, df $= 18$, $r = -0.476$, $p < 0.05$, $t = -2.232$) (Table 3). In another words, increased work on Sunday decreases employee feeling of rare happiness (Figure 2).

4 Discussion

Working in the evening and on weekends is not beneficial for the economy nor for well-being of employees. In essence, this research has shown that weekend or night work has no major impact on the economic activity. It does not increase productivity in terms of the economic growth, however it certainly maintains production or the provision of services (Becker et al., 2020).

Nevertheless, according to results work on Sunday has positive impact on life satisfaction. This can be explained by the Vroom's expectancy theory. Working on Sunday (exerted effort) results in a favourable performance (completed work). Favourable performance will result in a desirable reward (money, promotion, sense of accomplishment, appraisal). If the reward satisfies an important need then the desire to satisfy it will be strong enough to exert the effort. Consequently, meeting the desired needs can result in a feeling of life satisfaction.

On the contrary, work on Sunday decreases the feeling of happiness. It can be argued that it might be associated with less free time. As research shows, happy employees are more productive; hence, decreased happiness can negatively reflect on employee productivity during the week (Wang et al., 2022).

Furthermore, long working hours or work on weekend increases the energy consumption what leads to environmental problems. Though, reducing work in the evening or on weekends might be a significant problem for countries whose economy is based on production or services, for example Slovakia or Czech Republic. In the case of production, the reduction of weekend and evening shifts could be offered as a preventive measure, keeping morning or daytime shifts. These measures could help fulfil organizational goals, such as sustainability, efficiency, productivity and well-being of employees. In terms of services, shortened opening hours or changed mode of operation might manifest the measures. Adriano and Callaghan (2020) mentioned that in the less escalated periods it is also possible to use part-time employees and temporary employees who prefer to work on weekends because they have other responsibilities during the week or can earn extra pay. Many organizations can proceed with the transfer of services to the online space when they are closed (on Sundays or during holidays) based on the legislation in individual countries. Services are driven by customer demand, so the trend is to introduce days off when there is less demand for services (Monday) and extend opening times when there is demand for services (weekends, holidays).

On the basis of the current energy crisis and the sustainability of the business the question is which direction the organizations in individual countries will choose?

One of the sustainable development solutions in the global energy crisis seems to be a 4 days workweek. However, if the work of 5 days is crammed into 4 days with longer hours, it may not achieve the full range of benefits. Hence, it would be suitable to implement one of the following plans:

1. 4 days (8 -10 working hours) workweek,
2. 4 days (8 -10 working hours) workweek with 2 hours work from home every day,
3. 4 days (8 working hours) workweek with 5th day work from home.

Option 2 and 3 represent a hybrid-compressed workweek.

Another solution could be to offer flexible working hours to departments that need to work only in the specific time of the month, such as accounting or payroll. Many organizations in countries that are focused on manufacturing and services that cannot be

performed online do not have such extensive opportunities to implement a hybrid work model or to flexible working hours (Greve, 2019). Therefore, since communication is the driving force of employee satisfaction, the organization effort to show interest in employee needs will be valued more than benefits (Činčalová, 2020).

The aforementioned solutions could offer many economic and ecological benefits especially in the times of the energy crisis. A very negative approach will be the closing of factories and establishments that will not be able to pay their costs. In neutral cases, it will be switched to online mode mainly due to savings, which can have a negative effect on work life balance, as it was during COVID-19. The optimistic approach would be to continue mainly with option number 3. This approach is strengthened by the research from the pandemic period and could contribute to greater happiness.

In essence, it is quite clear that the mood and satisfaction of employees will change, the question remains in which direction (Perez et al., 2019) and whether the next few years will not be marked by macroeconomic aspects and the uncertainty of energy poverty. This would essentially cause a shift away from flexible forms of work organization, efficiency and happiness towards goals such as survival in the market.

4.1 Limitations

Further studies on work in the evening and on weekends and their impact on life satisfaction and happiness are required due to limited dataset. An extended dataset (for year 2022) would offer an interesting opportunity for further analysis. In 2022, an increased relevance of factors such as inflation, energy crisis or the need for sustainability of economic performance can change values to extremes.

Abstract

Research background: If the task of internal communication is to influence the company's business activities positively, then it has to be part of the company's strategic planning linked to communication and business goals. At the same time, it requires an understanding of the importance of internal communication and its potential for increasing the performance of companies associated with its application to management processes.
Purpose of the article: The article aims to research the impact of innovative tendencies, which, under the pressure of globalization factors, increasingly influence how internal communication is managed in the company. We pay special attention to the formation of the bottom wave and direct contact with the information source, such as employees, because it is the employees who are an essential information source for the company, which requires constant monitoring, impact evaluation and flexible reaction in interactions with the bottom wave.
Methods: To achieve the set goal, domestic and foreign published sources were analyzed, and case studies and research were used for deeper analysis. Synthetic-analytical and inductive-deductive methods were used as well.
Findings & Value added: We expect the results to provide insight into innovation implementation within internal communication, while considering the bottom wave in the global environment context.

companies try to penetrate beyond the borders of their country and enter the environment of international markets. In globalization, multinational companies are becoming decisive players, but smaller businesses that can respond flexibly to market changes also get a chance. (Lesáková, 2008) Entering international markets naturally increases the pressure to introduce innovations, increase the productivity and competitiveness of the company. Competition and global rivalry are growing in the movement of trade and resources across national borders. (Baláž, 2001) Nowadays, the competitiveness of companies is no longer just a relation to the products and services offered (Watson and Popescu, 2021, Mae et al, 2021).

2 The influence of globalization tendencies on the business environment

The globalization of the economy brings along new ways of doing business. It introduces innovations into internal company processes, mainly due to the development of communication and information technologies, the implementation of strategic business management, which nowadays has a fundamental impact on the company's success (Grant, 2021; Ionescu, 2021; Hopkins and Siekelova, 2021). Increasing employment brings with it a new level of competition in attracting qualified and motivated labour as an essential capital of the company. In this area, we also observe a shift in the direction of maintaining the workforce, increasing employee satisfaction and motivation.

2.1 Global trends in keeping workforce and employment

Technological progress, higher mobility of production factors, liberalization of international business, as well as the constantly growing number of countries entering the competitive relations of global business reduces the dependence of companies on the conditions of the domestic market and significantly motivate them to accept the conditions and trends prevailing on the global market. Just as globalization is a reaction to the oversaturation of domestic markets, it is also an effort to gain a foothold in prospective sales markets and the search for new and cheaper material and human resources. (Lesáková, 2008) In this process, international trends in human resources management come to the fore as a necessary and irreplaceable capital of the company. Employee orientation can be understood as a natural reaction of companies to the situation in the labour market because it is necessary to consider turnover and the resulting costs associated with another fulfilling job position. It is, therefore, necessary to create a system that ensures long-term cooperation between the company and its employees to prevent fluctuation. (Mruk et al., 2005)

Global trends in workforce retention include, among others, the efforts of companies to achieve a balance between work and private life and work-life balance. (Reed et al, 2020) A study researching international trends in employment and human resources on a sample of 738 top managers from the world's most developed regions such as the United States, Europe and Asia points to specific findings related to the retention of talented and experienced employees. Across all organizations in the studied regions, the following strategies for maintaining a qualified workforce and increasing employee retention come as the most important:
- achieving optimal compensation and benefits for attracting new and retaining current talented employees,
- the creation of employee engagement plans and open communication channels,
- creating and maintaining the environment of a learning society through education and development,

- implementing a talent management system for managing all aspects of the employee experience, from employee recruitment to maintaining long-term satisfaction. (Manhertz, 2011)

2.2 Global trends in human capital development in business practice

In human resources management, there is an obvious need to introduce the concept of "European-type" management, including its application in everyday practice. In this area, the following aspects are particularly preferred:

1) **Transformation of personnel activities -** represents the transfer of operative tasks to the hands of line managers. However, transforming a personnel manager from an administrator to a consultant is not without issues. They often show a reluctance or inability to perform personnel activities, while they may feel a weakening of their position, even a loss of control.

2) **Strategic planning, measurement and benchmarking –** in this area, it is essential to transform individual activities into human resources management. To obtain an up-to-date overview of the state of human capital in the company and the effectiveness of individual activities in people management, it is necessary to start from an overview of incurred costs, productivity indicators and indicators of effective management in certain areas of HR. The company should also follow them when planning its future goals, and they can also be used for external benchmarking.

3) **Outsourcing personnel activities –** closely related to monitoring the effectiveness of all activities of HRD. It is very popular nowadays to use a supplier to ensure several processes inside the company through external cooperation. It means that the external supplier will take responsibility for certain company activities. Several experts agree that outsourcing in HRD is one of the fastest-developing segments within the entire outsourcing market. It represents a revolutionary change in the delivery of services within the company. It helps to eliminate all repetitive activities, the added value of which is negligible for the enterprise. In this way, the company can focus on more critical activities. At the same time, there also exists the assumption that, based on the new structures, it will be possible to support a higher degree of innovation and flexibility. However, there are also certain risks, such as failure of outsourcing, lower quality, higher financial costs, leakage of know-how, leakage of strategic information, loss of control over HRD activities, etc. Despite the disadvantages above, outsourcing personnel activities is becoming a critical trend that determines the future of HRD. (Vetráková, 2011)

4) **Personnel marketing –** is a way to find and recruit quality personnel, stabilize them and strengthen their feeling of belonging to the company. With the help of personnel marketing, only those applicants who meet the predetermined conditions of the company are approached. This requires, in particular, analysis and evaluation of jobs, an analysis of potential job seekers' wishes, needs, interests and attitudes. The formation of work potential through personnel marketing leads to the emergence of a specific corporate and employee culture.

5) **Management of work performance –**represents a strategically oriented process enabling the company's employees to understand better what to focus on when performing their work and what they can achieve at work. At the same time, the prerequisite for proper functioning is constant communication between the employee and his superior. The goal of this process is the continuous improvement of work performance, which includes the planning and monitoring work performance, evaluation, training and development of the company's human capital and, last but not least, the method of rewarding them. The prerequisite for such an approach is to

increase employees' work performance by providing information about the company's strategic goals.

6) **Lifelong learning –** has become a necessity in companies nowadays. The knowledge of employees is already becoming a preferred economic category in our conditions, i.e., they are an essential factor in the economic prosperity of the company. Company management must begin to perceive the introduction of education as a primary process in the company. Determining the company's overall training strategy is no longer sufficient. Therefore, each employee in each workplace must have a training strategy to start employee training engagement in the company. The legislation of the Ministry of Education of the Slovak Republic could also serve to increase the motivation of employers to train their employees, which should also regulate the employer's right to participate in the evaluation of the level of informal education and the recognition of the results of informal education, as well as to use funding sources for lifelong education. (Seková, 2013)

The above-mentioned new trends point to the fact that nowadays, more and more emphasis is placed on the powers of employees to manage the company. It is the proper way to contribute to the motivation of employees, who will show better work performance, use their classification more effectively, thus making the work of line managers and individual HR departments easier. (Kachaňáková, 2007)

3 Implementation of innovations within internal communication

Economic entities must be able to adapt and adjust to global conditions. The world is currently reacting to significant economic challenges, either due to the pandemic or the social situation. These conditions are transformed into the growth of inflation, the decrease of disposable income and thus, the employees demand salary increases. Internal communication faces a great challenge, and it is essential to have it built on regularity, openness and integrity. (Hrnčáková, 2022; Ober and Kochmanska, 2022; Castro-Martinez and Diaz-Morilla, 2021) We can say that internal communication can very quickly connect with crisis communication in current conditions, the use of which can currently increase. In solving problems arising from a complicated social and economic situation, companies are forced to resort to the principles and methods of crisis communication directed at employees.

Taking care of employees is one of the pillars of socially responsible business and is also related to internal communication. "Studies by the World Health Organization estimate that 264 million people worldwide suffer from depression, many of whom also suffer from anxiety, costing the global economy an estimated $1 trillion a year in lost productivity." (WHO, 2021) Regarding this adverse trend, companies have to focus more on the issue of burnout, which threatens their employees. For this reason, the importance of employee feedback has increased, which could represent one of the indicators of incorrectly set functioning of the company considering redistribution of tasks or internal communication. (Duvigneau, 2022) As mentioned, the company needs to set a strategy aimed at optimal management of employees, which is also transferred to internal communication.

As such, the pandemic has significantly changed the functioning of the entire world. We conclude that it also affected internal communication. Experts pointed out one of the significant trends: the effort to inform employees effectively and interestingly. Companies had to develop a strategy that covered the reach of information to all workers, including those who work outside the workplace. In addition, companies focused on diversified forms of communication, which ensured that employees at all levels of management were adequately informed. (Koliyot, 2022) Solving the pandemic situation in connection with internal communication has thus brought greater visibility even to workers who are not

primarily tied to a standard place of performance. Companies were therefore interested and motivated to link the entire company's communication and ensure the flow of information. According to research, adopting digital tools leads to a 67% increase in productivity, a 53% increase in employee engagement and a 43% increase in revenue. (IBM, 2019) Therefore, as a result of the pandemic, companies found a way or were forced to find a way to ensure company-wide internal communication and connect remote employees.

Just as companies change the formats used for external communication according to current trends and recipient requirements, they should also change the formats used for internal communication. Companies should perceive the change in format and the use of, e.g., video content or another visual format, not only as a way to attract new customers but also as a way to increase productivity and employee engagement. Up to 67% of employees showed better results in completing tasks when information included text with images or video than information that contained only text. The research also pointed to faster absorption of information, by 7%, if the company communicated with a message with an image and not only with text. (Knott, 2022) We can conclude that companies are forced to reevaluate their communication strategy aimed at internal audiences and try to communicate more effectively with their employees.
Source: (Knott, 2022)

New technologies affect the operation of economic entities as well as internal communication. An inherent trend that companies will have to adapt to is the Metaverse. The pandemic has already shown the importance of platforms that connect people. This platform represents a fusion of the digital and physical worlds in which users will spend their time. (Michalko, 2022) "It is based on the convergence of technologies that enable multi-sensory interactions with virtual environments, digital objects and people as virtual or augmented reality." (Mystakidis, 2022) By 2026, it is predicted that more than 10 trillion dollars will be invested in it. (Patel, 2022)

Metaverse can be a tremendous technological milestone to remove physical contact from the work-legal relationship while at the same time eliminating distance, and formal meetings can be transferred to an accurate simulation of the office, in which all colleagues will participate in the prescribed dress code. (Michalko, 2022) Thus, Metaverse will bring the potential for real-time experiences and connection to a hybrid or remote workforce. (Patel, 2022) According to experts, Metaverse has the potential for radical innovations in education, laboratory simulations (e.g., safety training) development of procedural skills necessary for the medical field or other education. (Mystakidis, 2022)

In addition, the company Meta Platforms is also working on artificial intelligence research that will allow people to communicate more naturally using voice assistants or naturally translate between different languages. (Michalko, 2022) This form can also influence internal communication and define its future direction.

Of course, the most significant disadvantages of this new platform are the cost. Businesses will have to invest significant funds in sophisticated software and hardware. Legal regulation that protects the privacy and information of interested parties is also essential. Such legislation is currently absent. (Patel, 2022)

4 The bottom wave phenomenon and its shift into the company's internal communication

The rise of social networks enabled the interactive exchange of information and permanently changed the business environment. Social networks have brought new possibilities to the internal company environment, such as expanding the communication mix with a new platform. In some cases, they also serve as a sales channel characterized by constant interaction with the audience. Employers agree that social networks belong to the workplace, offering employees various internal communication platforms, corporate social networks that are accessible only to internal users. Thus, users share diverse content in an enterprise environment, collaborate, communicate, share, give feedback, ask questions and make recommendations. (Pavithra and Deepak, 2021) With the correct setting of the internal communication strategy, companies can benefit in various ways from using internal social networks. Among the benefits, we include an increase in work productivity, an increase in the motivation and engagement of employees. (Benner and Tushman, 2003)

Organizations must analyse, monitor, and evaluate internal social network data to understand their employees better. Employees are becoming content creators for the organization as well as brand ambassadors, as a result of which the boundary between internal and external communication is constantly shifting. Studies show that when employees are encouraged to share their personal opinions, expertise and knowledge through social networks, they become more engaged. (Ewin et al., 2019)

The development of communication through social networks requires the modification of conventional approaches, including in the field of internal communication, affected by the significant onset of the bottom wave phenomenon. Succeeding in the bottom line means listening to your own customers, employees in your company, and people from other companies who comment on the topic. (Li and Bernoff, 2010) The bottom wave phenomenon deeply affects the internal corporate environment, as employees obtain information about their employer from various platforms based on social networks. When researching the phenomenon of the bottom wave in the company's internal communication, it is necessary to mention that the bottom wave is associated with informal communication using unofficial communication channels. Informal communication creates the basis for the growing social phenomenon of the bottom wave. (Švec et al., 2021)

5 Methods

The contribution is processed on the basis of a detailed analysis of secondary sources, while the aspect of relevance and topicality was followed. Domestic and foreign resources were used, such as scientific monographs, specialist periodicals related to the topic and scientific contributions from journals and conference proceedings. The paper used the inductive-deductive method, analysis, and synthesis.

6 Results and Discussion

We can state that labour-legal relations from the point of view of communication are subject to inherent changes. The pandemic contributed to changes in internal communication, as it was an inevitable step. The pandemic supported the implementation of several changes. Work-life-balance is a global trend in the field of maintaining the workforce. We consider this trend to be one of the key ones, as it has set a new approach to working life. Also based on this trend, changes took place in internal communication.

An integral part are trends that are increasingly used in company communication towards employees. The use of new technologies is a never-ending process that is inevitable. In our opinion, innovations in the field of communication are moving forward very quickly and the question is how companies will be ready to implement them. The financial and time aspects of implementation will be crucial for companies.

Companies must not forget the natural development of internal communication. Organizations must analyse, monitor, and evaluate internal social network data to understand their employees better. It is necessary to analyse social networks and monitor the interests of employees from the point of view of the means of communication used. We consider this an important step

The role of internal communication is to positively influence the company's activities, and thus it has to be part of the company's strategic planning, which is linked to the goals. Internal communication has potential for company performance associated with its application to management processes. It is essential that there is a constant examination of internal communication and an understanding of the required formats and options from the perspective of employees. If the company wants to progress, it is important that it has primarily functioning internal communication. Communication is subject to constant dynamics. Constant innovations and new trends bring improvement for companies. We assume that the constant influx of new trends will be crucial for companies, and it will be necessary to introduce these innovations into the company's operations.

The impact of the global COVID-19 pandemic on the teaching of the university students at selected university

Markéta Beranová[1,*], and *Miroslava* Navrátilová[1]

[1] Czech University of Life Sciences in Prague, Faculty of Economics and Management, Department of Economics, Kamýcká 129, Prague, 165 21, Czech Republic

Abstract

Research background: The COVID-19 pandemic has had an impact on the entire contemporary globalized world. One of the areas most affected by the pandemic was education at all levels. The rapid transition to online teaching and self-study was a big challenge for students and their teachers. The COVID-19 pandemic has affected education around the world.

Purpose of the article: The aim of this paper is to evaluate the impact of the global COVID-19 pandemic on the teaching of university students at selected university in the Czech Republic.

Methods: Primary data were obtained by quantitative research using a questionnaire survey (n = 306) in 2020 amongst full time bachelor and master degree students at selected university in the Czech Republic. The research was focused on the impact of the COVID-19 pandemic on the teaching of university students. In the analytical part of article was used testing of statistical hypotheses.

Findings & Value added: Teaching at the university level has been moved to online mode. Distance learning has fully replaced face-to-face learning. This method of teaching brought with it pros and cons. For more than 60% of respondents, the possibility of collaborating with other students in subjects in the online mode was worse than with the normal teaching style. Only 30% of the respondents felt as part of the study group as with the regular teaching style. Interest in studies, subjects and their content was the same for 45% of respondents. The transition to online learning during the global pandemic crisis brought with it challenges and obstacles for both students and educators.

1 Introduction

The Covid-19 pandemic has undoubtedly affected the entire globalized world. The crisis has affected all areas of life, including education at all levels. Higher education, where teaching has its own specificities, was no exception (Ashour, El-Rafae and Zaitoun, 2021; Daniels, Geodan and Parker, 2021). The crisis brought with it new challenges and new possibilities in teaching. At the time of the most severe crisis, it was necessary to close the faculties and switch from face-to-face teaching to online teaching (Daumiller et al., 2021). In the spring of 2020, educational institutions began to gradually close throughout the globalized world. At all levels of education, there has been a shift towards a distance learning style (Abumalloh et al., 2021).

The Czech Republic was no exception. For the first time ever, education was transferred to an online environment on such a scale. Online learning environment is completely different from regular classroom learning. Changes occur in all areas, including student and teacher motivation, satisfaction, but also the interaction between student and teacher and students together (Gopal, Singh and Aggarwal, 2021; Selvaral et al., 2021; Muthuprasad et al., 2020).

As stated by many authors (Habib et al., 2021; Yunusa and Umar, 2021; Su and Chan, 2020), in the last two years, the most technological platforms for teaching support have been adopted at the level of higher education. These tools are considered indispensable and very important during the pandemic - they provide many functions - administration, organization of lessons, classification, testing, communication with students (Turnbull, Chugh and Luck, 2019). As they stayed (Agyeiwaah et al., 2022) *"Nonetheless, questions about the specific online attributes such as ease of use, attractiveness, practicality, and efficiency that have a significant impact on their learning satisfaction have received limited academic inquiry"*, this is confirmed by many other authors (Wang, Liu, & Su, 2021; Dhawan, 2020).

The aim of this paper is based on primary research conducted at selected university in the Czech Republic to evaluate impact of the global COVID-19 pandemic on the teaching of university students. This article contributes to the theoretical, practical and methodological understanding of university students' satisfaction with online teaching methods, which have become an irreplaceable tool in education in times of crisis.

The theoretical framework is presented in the Introduction. The Methods chapter deals with the method of performing the primary research and the description of the surveyed sample of respondents in terms of basic sociodemographic characteristics. The Results and Discussion chapter presents the results of the survey and includes a discussion and a comparison of the outcomes of our research with similar surveys in terms of the investigated issues. The most important findings are shown in the Conclusion chapter.

2 Methods

The theoretical framework of this article has been elaborated through the method of document research using scientific articles, books and data from internet. Primary data were collected using a questionnaire survey. The questionnaire survey was realized on-line in 2020. The respondents were full-time students at selected university in the Czech Republic. In total, 306 (n = 306) respondents took part in the primary research.

Basic sociodemographic factors of the reference group of respondents were as follows in the Table 1:

Table 1. Sociodemographic factors of respondents, in %

Gender	Female	70.59
	Male	29.41
Level of study	Bachelor's degree (BD)	55.88
	Master's degree (MD)	44.12

Source: own research (2020)

2.1 Statistical Tools for Analysis

The contingency table is used it for transparent visualization of mutual relations of two statistical variables. The type of the contingency table is given by the number of rows r and the number of columns s, it means r × s (Hendl, 2009). Obviously, χ^2 is a measure of the overall dissimilarity of n_{ij} and m_{ij}. The greater the difference between the observed and the expected values, the higher the test statistic χ^2.

$$m_{ij} = \frac{n_i . n_j}{n} \tag{1}$$

$$\chi^2 = \sum_{i=1}^{r} \sum_{j=1}^{s} \left(n_{ij} - m_{ij} \right)^2 / m_{ij} \tag{2}$$

i and j are indices of rows and columns, nij are observed frequencies, ni and nj are marginal totals, n is grand total of observations, mij are expected frequencies. We compare χ^2 to the critical value χ^2 with a chi-square distribution of (r-1) (s-1) degrees of freedom at the chosen level of significance (α = 5%). We reject the hypothesis if χ^2 is larger than the table value. This test is valid asymptotically and, thus, can only be applied if there are enough observations. All expected values ought to be higher than one [9]; at the same time, the table should not contain more than 20% of theoretical incidence rates (frequencies) of less than 5. Where zero values occur in any of the fields, we proceed to analyse a derived table, created by merging a small number of categories (Hindls, 2007). Cramer's V was used to determine the degree of association between the variables. Additionally, the method of adjusted residuals was applied. The calculation of adjusted residuals indicated precisely the location of the dependency. The results of adjusted residuals are included in the tables for zero hypotheses. The principle of adjusted residuals is based on comparing the values in the cells of the contingency table with the critical value of 2 (or 1.96). The comparison was performed and, considering that wherever the value in a cell equals or exceeds 2 (-2) a statistically significant difference exists, the dependency was confirmed. This method was enhanced by the sign scheme. Information on where the assumption of independence of both the compared characteristics was violated could be obtained through this method.

The data analysis was focused on the following tested hypotheses.

H01: The motivation to successfully complete a course in online teaching does not depend on the gender of the respondent.

H02: The motivation to successfully complete a course in online teaching does not depend on the level of study of the respondent.

3 Results and Discussion

In this chapter, the results of the primary research in the field of online teaching are presented, including comments. The next part is discussion, where the comparison of the

final results of the own research with similar studies in the context of the issue is carried out.

First, it was determined whether students are generally satisfied with the various aspects of online teaching that have been used at the university. Of the total number of respondents, 71.57% (219) are satisfied with online teaching and 28.43% (87) are not.

Table 3 shows the opinion in opportunity to collaborate with other students in subject. The possibility of cooperation with other students in a study group is crucial in some subjects. In this case, it can be seen from the results that this option was limited during online teaching - which was stated by more than 61% of respondents. Almost 30% of respondents said that this opportunity is the same for them, and less than 10% of respondents consider the opportunity for cooperation to be better.

Table 3. Opportunity to collaborate with other students in subjects, in %

Gender/ response	Same as face-to-face study	Better / bigger than face-to-face study	Worse / less than face-to-face study	Absolute frequencies	Relative frequencies
Female	19.61 %	6.54 %	44.44 %	216	70.59 %
Male	9.48 %	2.94 %	16.99 %	90	29.41 %
Total	29.08 %	9.48 %	61.44 %	306	100 %

Source: own research (2020)

Table 4 shows the interests of students in the content of taught subject. In terms of interest in the studied subject, more than 45% of respondents indicated the same interest in the content of the studied subject as in the classical style of teaching. Almost 17% of respondents even stated that their interest was higher and less than 38% of respondents characterized their interest in the content of the studied subject as worse during online teaching.

Table 4. Interest in the content of taught subjects, in %

Gender/ response	Same as face-to-face study	Better / bigger than face-to-face study	Worse / less than face-to-face study	Absolute frequencies	Relative frequencies
Female	33.66 %	12.09 %	24.84 %	216	70.59 %
Male	12.09 %	4.58 %	12.75 %	90	29.41 %
Total	45.75 %	16.67 %	37.58 %	306	100 %

Source: own research (2020)

Table 5 shows the feeling that I am part of a class / circle that I belong somewhere. The students' feeling that they are part of the study group has worsened for more than 63% of respondents. Almost 40% of respondents consider this feeling at the same level. And less than 7% of respondents spoke in favour of improvement.

Table 5. My feeling that I am part of a class / circle that I belong somewhere, in %

Gender/ response	Same as face-to-face study	Better / bigger than face-to-face study	Worse / less than face-to-face study	Absolute frequencies	Relative frequencies
Female	22.55 %	3.92 %	44.12 %	216	70.59 %
Male	7.84 %	2.61 %	18.59 %	90	29.41 %
Total	30.39 %	6.54 %	63.07 %	306	100 %

Source: own research (2020)

An essential issue of online teaching is also the motivation to study and complete the subject with successful completion. In this case, 37.1% of the respondents stated that it is not a problem for them to stay motivated to successfully complete the course during online teaching, as in the case of regular teaching. However, 36.8% of respondents stated that it is a big problem for them compared to contact teaching. On the contrary, 26.1% of respondents state that motivation to successfully complete the subject is less of a problem for them than with the usual teaching method.

Table 6 contains the results of the tested null hypotheses.

Table 6. The structure of the hypothesis calculation – motivation of students

Hypothesis No.	Wording of the zero hypothesis	χ^2	Critical value	H0 can be rejected	Cramer's V
$H0_1$	The motivation to successfully complete a course in online teaching does not depend on the gender of the respondent.	9.70	5.99	X	0.06
$H0_2$	The motivation to successfully complete a course in online teaching does not depend on the level of study of the respondent.	5.53	5.99	-	-

Source: own research (2020)

$H0_1$ - The value of the χ^2 statistic is higher than the critical value at the 0.05 significance level. The null hypothesis can be rejected. Thus, the dependence between whether the motivation to successfully complete a course in online teaching and the gender of the respondents is proved. The value of Cramer's V is at the level of 0.06, and it is, therefore, a very weak dependence. $H0_2$ – The value of the χ^2 statistic is lower than the critical value at the 0.05 significance level. The null hypothesis cannot be rejected. Dependence was not demonstrated in the case of the variable (level of study).

Student satisfaction is defined as students' ability to compare the desired benefit with the observed effect of a particular product or service (Budur, Faraj and Kamir, 2019). In particular, the quality of the e-learning system contributes significantly to student satisfaction, which includes attributes such as usefulness, informativeness, good visual appeal and easy navigation on the educational platform (Perifanou, Economides and Tzafilkou, 2021; Pham et al., 2019). In terms of motivation for successfully completing the course, more than 37% of respondents indicated a problem in this area. Similar results were also encountered by the authors (Vielma and Brey, 2021), who add that the self-motivation to successfully complete the subject can be impaired by, for example, lack of concentration, lack of time to watch online lectures, and also the lack of an academic environment that requires their attention. More than 60% of respondents cited the opportunity to collaborate with other students as worse compared to classic face-to-face teaching. Likewise, almost 64% of respondents said that they did not feel that they belonged to their study group. Both aspects were undoubtedly caused by the loss of personal academic interactions – both between students and between students and teachers (Hill and Fitzgerald, 2020; Vielma and Brey, 2021).

4 Conclusion

The COVID-19 pandemic has had an impact on the entire contemporary globalized world. One of the areas most affected by the pandemic was education at all levels. The presented article dealt with the evaluation of the impact of the COVID-19 pandemic on the teaching of students at a selected university.

Overall student satisfaction with online teaching is at a very good level. The area of cooperation between students has worsened for more than 60% of them. Interest in the stage of the given subject and its content remained the same for almost 50% of the students as in classical teaching. The impact of online teaching on the feeling that the student is part of the study group was critical - here almost 70% of respondents reported a deterioration compared to face-to-face teaching. The results show that the rapid transition to online teaching was a challenge not only for teachers, but also for the students themselves.

The research was performed at the selected universities in the Czech Republic only, which may be considered as a limitation. Another direction of research could be to compare teaching in the post-covid era - i.e. to return to the classic teaching model.

Abstract

Research background: The current pandemic era with global overlaps creates a room for market segmentation. Lifestyle monitoring is based on a combination of activities, interests, and opinions (AIO) with respect for social consequences in order to increase the quality of life.
Purpose of the article: The aim of the paper is to analyse, compare, and predict the consumer behaviour in the meat market in the V4 countries and outline the possible social consequences of this consumer demand on the quality of life.
Methods: The paper will use data from the FAO database on meat consumption and life expectancy, as well as the results of a survey conducted in the Slovak Republic. The time span of the research is from 1961 to 2030. The obtained data will be processed by methods of quantitative and qualitative statistics.
Findings & Value added: The ambition of the paper was to provide a multidimensional view of consumer behaviour in the consumption of meat, as statistically proven results in this area encourage a change of lifestyle in order to achieve a higher quality of life.

Keywords: *market segmentation; meat consumption; life expectancy*

JEL Classification: *M31; E71; I10*

1 Introduction

To achieve overall health, everyone needs a healthy diet, regular physical activity and a healthy body weight. In the recent years, there has been a dramatic increase in overweight

---

[*] Corresponding author: janka.beresecka@gmail.com

and obesity levels in the EU population, especially in the children. In the long run, this trend will have a negative impact on life expectancy in the EU and a reduced quality of life for many people (MPSR.sk, 2008). Small changes in eating habits and regular physical activity can have a major impact on quality of life, and also lower health care costs (Europa.eu, 2020). Food provides us with energy, protein, vital nutrients, happiness, and joy. On the other hand, if chosen incorrectly, processed food can cause disease, death, misery and despair in people (Jespersen, & Huffman, 2014). This contrast can also be influenced by climatic and natural conditions, the administrative division of the country, denominational contexts, migratory flows and historical events, ie factors that also call for the formation of the culture of the population (Urbanová and Michalík, 2018). In both theoretical and practical terms, there is a relationship between food and consumers. The role of consumer behaviour is also to find a link between people representing a certain lifestyle and consumption pattern (Chreneková and Dubcová, 2017). Properties, health, appearance and quality of food play an important role in the decision-making process and the purchase of the product itself, which can be considered a decisive criterion shaping the quality experience, satisfaction or dissatisfaction of the consumer and his future purchase (Banović et al., 2009).

Meat and meat products are an integral part human diet (Henchion, et al., 2014). Given some concerns about the negative effects of meat on the health of consumers, new functional meat products must be tasty with better nutritional value. The main reason for the reluctance of European consumers to accept functional food products is the dilemma between health-promoting values and their natural taste (Grunert, 2010). One of the most important factors that consumers perceive is meat quality, taste and overall satisfaction (Verbeke et al., 2010). These factors were added by other authors to their flavour, juiciness, freshness, leanness, healthiness and nutritional value, and brands or labels referring to process characteristics or quality control (Banović et al., 2009). The current level of meat consumption affects the environment and health, and it is emphasized the need to reduce meat consumption and increase interest in a plant-based alternative to protein (Stubbs et al., 2018).

A certain lifestyle represents the way a person lives, and it is helpful in predicting shopping and consumer behaviour. It is an expression of a person's individuality, a specific demonstration of an individual or a social group. Connecting the concept to sociology, it is connected with the terms way of life and standards of living, while these terms, by their nature, fit into the context of the life quality definition (Chreneková, & Dubcová, 2017). Researchers have examined and published exploratory studies looking for a relationship between lifestyle entrepreneurship and the quality of life. This relationship, complemented by the attributes of need, consumption, and food safety, is often perceived in a multidisciplinary way and is linked to global megatrends. Megatrends will lead to meaningful long-term changes that will affect economic, political, environmental, technological, but also social issues. They present new and often invisible challenges, threats and opportunities, the impact of which may vary between the economy as a whole and individual sectors. Key facts and forecasts include food production and waste minimization, which have a number of consequences for sustainability (Marcketti, et al. 2006). The shift in consumer behaviour, the growing need for exclusivity and individualism, more experienced, more critical, and more sophisticated travellers who care about quality of life are also attributes that influence the direction of not only the country's economic development (Beresecká et al., 2018).

2 Methods

The work contains secondary and primary data obtained by the method of a questionnaire survey. The collection was carried out in the time horizon from January to June 2017. A total of 931 respondents participated in the survey. For the purposes of processing the contribution, questions concerning consumer behaviour on the market in meat and meat products are purposefully specified: Do you consume meat and meat products? How often do you eat different types of meat - poultry, beef, pork and game? Part of the methodology was the formulation of hypothesis H: Is there a direct relationship between meat consumption and life expectancy? The search for answers and processing of the obtained data was based on the basic approaches used in the statistical analysis of time series, which serve to explain the development of the investigated quantity, but also to a qualified prediction of the estimate of its value in the following periods.

The meat consumption data used (beef, game, pork and poultry) were obtained from the FAO website (FAO.org, 2020). In the case of research in Hungary and Poland, data for the years 1961-2013 and the Slovak Republic and the Czech Republic for the years 1993-2013 will be processed. Due to the longer time series in the case of Hungary and Poland, it was possible to statistically express the prediction of the development of consumption of individual types of meat until 2030. Due to the division of the federal state Czechoslovakia, it was possible to lay out predictions in these countries only until 2020. The method of regression and correlation analysis was used to identify and mathematically describe the statistical dependence between quantitative statistical features. In the case of assuming that between the dependent variable Y and the explanatory (independent) variables Xi i = 1, 2, ... k the dependence is described by the equation:

$$Y = f(X_1, X_2 \dots X_k, \beta_0, \beta_1 \dots \beta_k) + \varepsilon \qquad (1)$$

which the authors estimate:

$$yj' = f(x_{1j}, x_{2j} \dots x_{kj}, b_0, b_1, b_k) \qquad (2)$$

The null hypotheses tested relate to the significance of the locating constant (Intercept) and regression coefficients (b1, b2, b3, b4), with the null hypothesis asserting the insignificance of the relevant coefficient, and the alternative hypothesis asserting its significance. If the P-value is> 0.05, the coefficient is statistically insignificant, if the P-value is <0.05, the coefficient is statistically significant (Beresecká and Svetlíková. 2020).

3 Results

The Slovak Republic is a landlocked country in Central Europe. The total area of the country is 49,035 km2, water areas occupy 931 km2 (i.e. 1.9%) (Europa.eu, 2020b) with human development index 0.857 (UNDP.org, 2020). The average life expectancy is 77.4 years (2018) (Europa.eu, 2020a). Agriculture in this country is of declining importance. In animal production, the number of livestock is gradually decreasing. The most significant decline is in pigs and cattle. Sheep farming is consistently low. The most numerous are poultry conditions. The Czech Republic has the total area of the state is 78,868 km2, water areas occupy 2.0% (Europa.eu,2020b) with human development index of 0.891 (UNDP.org, 2020). The average life expectancy is 79.2 years (Europa.eu, 2020a). The country is known for its old tradition of industrial production and its developed agriculture. The basis of animal production is the breeding of cows, pigs, poultry, and beekeeping. The Republic of Hungary occupies an area of 93,011 km2, water areas represent 0.74% (Europa.eu, 2020b) with human development index of 0.845 (UNDP.org, 2020). The average life expectancy is 76.7 years (2018) (Europa.eu, 2020a). Agriculture has suitable

conditions mainly due to favourable climatic conditions and quality soil, which occupies about 60% of the country's surface. Both animal and crop production is widespread. Livestock production is dominated by pigs, cattle, horses, sheep, and poultry. The Republic of Poland has an area of 312,679 km2, water accounts for 3.07% (Europa.eu, 2020b) with human development index of 0.872 (UNDP.org, 2020). The average life expectancy is 78.5 years (2018) (Europa.eu, 2020a). Poland is an important agricultural country based on a very strong agrarian tradition. It is the largest producer of poultry meat in the EU in terms of meat production (MZV.sk, 2020).

This section of the paper informs and compares the development of meat consumption in the V4 countries based on data from OECD (2021). In Slovakia, between the years 2013-1993, there was a decrease in consumption of beef by 69.49%, game 8.99% and pork by 32.02%. Poultry consumption increased by 120.55%. In the Czech Republic, in 2013-1993, there was a decrease in consumption of beef by 60.51% and pork by 29.41%. Consumption of poultry increased by 57.90% and game by 29.30%. The results show that in Hungary, compared to 1961, beef consumption fell by 8.66% compared to 1961. Consumption of game in the observed period decreased by 3.51% and consumption of poultry increased by 133.62% and consumption of pork increased by 21.90%. In 2013-1993, there was a further decrease in beef consumption by 72.35% and also a decrease in pork by 38.84%. On the contrary, game consumption increased by 14.55% and poultry consumption by 8.29% in the observed period. In Poland, between 1993 and 1961, consumption of game meat decreased by 66.15% and consumption of beef increased by 39.78%, pork by 47.21% and poultry by 463.25%. In 2013-1993, a decrease in consumption of beef by 82.15%, game in 36.36% and pork by 8.33% was recorded. An increase in consumption of 193.16% was recorded only for poultry meat.

The results of the questionnaire survey indicate that out of all, 785 respondents (84.32%) consume meat, 112 respondents (12.03%) consume meat only occasionally, and 34 (3.65%) do not consume meat at all. Furthermore, the results of the survey show that respondents consume poultry the most. This frequency was also reflected in the average consumption of poultry meat of all respondents (Figure 1). Pork is consumed by respondents on average once a week, and beef is consumed by respondents on average once a month. These types of meat have a significantly higher price than others, which is likely reflected in the infrequent consumption, despite the health-promoting substances that these types of meat contain. Likewise, respondents rarely consume game.

	Every day	Multiple times a week	Once a week	Once a month	Rarely	I do not consume at all
■ Game	0%	2%	4%	10%	53%	31%
■ Poultry	6%	61%	26%	3%	3%	1%
■ Pork	1%	24%	39%	18%	11%	6%
■ Beef	0%	5%	24%	30%	30%	11%
Figure 1. Frequency of meat consumption in the SR

Source: own processing (2020)

Based on the results of primary research in the Slovak Republic, the authors examined the consumption of individual types of meat in the V4 countries from 1961 to 2013 based on the FAO database, and through prediction since 2014. The results are shown in the following Figure 2. In the predicted period of years 2014-2020 in Slovakia and the Czech Republic, it is possible to expect a decrease in beef consumption in Slovakia by 113% in the Czech Republic by 45.66%, and also a decrease in pork consumption in Slovakia by 15.57% and in the Czech Republic by 4.13%. On the other hand, poultry consumption in Slovakia is expected to increase by 18.39% and in the Czech Republic by 11.11%, and game in Slovakia by 17.62% and by 9.99% in the Czech Republic.
Figure 2. Prediction of meat consumption in V4 countries

Source: FAO database (FAO.org, 2020), own processing

According to the data, Poland and Hungary show a longer time development, it was possible to statistically express a prediction for a longer period of time - until 2030. In Poland, a reduction in beef consumption by 22.61% in 2014-2020 can be expected and game by 39.08%, and an increase in consumption of pork by 3.67% and poultry by 11.51%. In Hungary in 2014-2020, it is assumed that there will be a decrease in consumption of beef by 30.6% and pork by 4.04%, and an increase in consumption of poultry by 7.74% and game by 1.5%. In the years 2020-2030, a further reduction in the consumption of beef is expected by 49% and game by up to 107%, and an increase in the consumption of pork by 6% and poultry by 17.25%. In Hungary, a further decrease in consumption of beef by 73.5%, pork by 7.02%, and an increase in poultry by 11.97% and game by 2.47% can be expected.

Knowledge of the independent development and consumption of uniform types of meat in a regional sense is important in connection with consumer behaviour and with lifestyle, but the weight of importance must be linked to an indicator that is important for citizens. The present time points to the need for quality in a broader sense, not excluding the quality of life. The quality of life can also be expressed by the achieved average life expectancy, the results of which are shown in Figure 3.

	Slovak Republic	Czech Republic	Poland 2020	Poland 2030	Hungary 2020	Hungary 2030
Average life expentancy	77,27	80,12	76,73	78,21	73,85	74,87
Percentage change	0,0158	0,0209	0,0117	0,02	0,008	0,0138
Figure 3. Comparison of development and changes in life expectancy in V4 countries

Source: own processing (2020)

In 2020, an increase in life expectancy is expected compared to 2014 in all compared V4 countries, but in a different manner in each one. In Slovakia, life expectancy should increase by 1.2 years (1.59%) to a life expectancy of 77.27, in the Czech Republic by 1.64 years (2.09%) to a life expectancy of 80.21, in Poland by 0.88 years (1.17%) to the level of 76.73 life expectancy and in Hungary by 0.61 years (0.84%) to the level of 73.85 life expectancy. In 2020-2030, a further increase in life expectancy in Poland is expected to rise by 1.47 years (2%) to a life expectancy of 78.21, and in Hungary by 1 year (1.39%) to a life expectancy of 74.88.

Based on the acquired extended knowledge, the authors sought an answer to the question asked: Is there a direct relationship between meat consumption and life expectancy? The authors of the paper have obtained a measurable answer by calculating the dependence, the results of which are shown in the following Table 1.

Table 1. Dependence of meat consumption with the development of life expectancy

Indicator	Slovakia	Czech Republic	Hungary	Poland
Multiple R	0.977168	0.9662969	0.9456096	0.985977
R Squared	0.954857	0.9337297	0.8941776	0.972151
Significance F	4.039E-2	3.1508E-1	5.981E-3	9.323E-5
Intercept	77.41682	83.973184	77.096824	69.97525
beef	-0.25076	-0.700954	-0.18929	-0.01976
pork	-0.05199	0.3761314	-0.008685	0.077349
poultry	-0.03026	-0.218404	0.0631573	0.307372
game	0.794355	1.1017188	1.1764757	1.099024

Source: own processing (2020)

Value Multiple R (multiple correlation coefficient): the closer the value is to 1, the stronger the dependence. In our example, there is a high degree of dependence of the relationship between average life expectancy and consumption of individual species of meat in all compared V4 countries. The value of R Square is the value of the coefficient of determination, which after multiplication by 100 (%) indicates, that the chosen regression function explains the variability in meat consumption to about that percentage; the rest represents unexplained variability, the influence of random factors, and other non-specific influences. In the ANOVA part, the null hypothesis is tested, which states that the chosen

model to explain the dependence (linear model) is not suitable, the alternative hypothesis states the opposite. An F test was used to evaluate this assertion.

Significance value F in SR = 4,039.10-15 <0.05. The authors reject H0, which means that the model was chosen correctly. The linear model was suitable for all V4 countries based on the significance value F.

The regression function of Slovakia: $y' = 77.41 - 0.25x_1 - 0.05x_2 - 0.03x_3 + 0.79x_4$

The regression function of Czechia: $y' = 79.94 - 0.98 x_1 + 0.26 x_2 - 0.38 x_3 + 0.62 x_4$

The regression function of Hungary: $y' = 75.14 - 0.26x_1 - 0.03x_2 + 0.01x_3 + 0.5x_4$

The regression function of Poland: $y' = 68.25 - 0.06x_1 + 0.04x_2 + 0.26x_3 - 0.74x_4$

The locating constant is statistically insignificant. This means that with zero consumption of individual types of meat, the authors of the article cannot expect an increase in average life expectancy. The P-value for the regression coefficient b1 (beef consumption in kg/person/year) is 7.55.10-5 <0.05 in Slovakia, which confirms the significance of this coefficient. Its real value is -0.25, which means that with an increase in beef consumption by 1 kg, a decrease in average life expectancy by 0.25 years is expected. In each of the V4 countries, the acquisition P-value is less than 0.05, which confirms the significance of this coefficient, the real values are also negative. In the Czech Republic, its value is -0.7, which means that with an increase in beef consumption by 1 kg, a decrease in average life expectancy by 0.7 years is expected, in Hungary a decrease in average life expectancy by 0.18 years is expected, and in Poland about a decrease by 0.01 year. The P-value for the regression coefficient b2 (game consumption in kg/person/year) in Slovakia is 7.02.10-6 <0.05, which confirms the significance of this coefficient. Its real value is 0.79, which means that with an increase in consumption of game by 1 kg, an increase in average life expectancy by 0.79 years is expected. In each of the V4 countries, the P-value is less than 0.05, which confirms the significance of this coefficient, but the real values are positive. In the Czech Republic, its value is 1, which means that with an increase in beef consumption by 1 kg, it is possible to expect an increase in average life expectancy by 1.1 years, in Hungary, an increase in average life expectancy by 1.17 years, and in Poland by 1, 09 years. The P-value for the regression coefficient b3 (pork consumption in kg/person /year) is 0.005 <0.05 in

Slovakia, which confirms the significance of this coefficient. Its real value is -0.05, which means that with an increase in pork consumption by 1 kg, it is possible to expect a decrease in the average life expectancy by 0.05 years. In the Czech Republic (0.37) and Poland (0.07), real values acquire positive values, which means that with an increase in consumption of pork by 1 kg, it is possible to expect an increase in the average life expectancy in the Czech Republic by 0.37 years, and in Poland by 0.07 years. Hungary (-0.008) has a negative coefficient of 0.008, which means that with an increase in consumption of pork by 1 kg, a decrease in average life expectancy by 0.008 years is expected. The P-value for the regression coefficient b4 (poultry meat consumption in kg/person/year) is 0.004 <0.05 in Slovakia, which confirms the significance of this coefficient. Its real value is -0.03, which means that with an increase in the consumption of poultry meat by 1 kg, it is possible to expect a decrease in the average life expectancy by 0.03 years. A similar situation is also in the Czech Republic, where the value of the coefficient is negative, namely - 0.21, which means that with an increase in the consumption of poultry meat by 1 kg, it is possible to assume a reduction in average life expectancy by 0.21 years. The situation is the opposite in Hungary (0.06) and Poland (0.3). With an increase in the consumption of poultry meat by 1 kg, the average life expectancy is expected to increase in Hungary by 0.06 years and in Poland by 0.3 years.

The results above presenting a high dependence between the examined indicators can be used in practice. One of the possibilities is to influence the modification of consumer behaviour through changing the view of meat pricing in the studied countries, of the

amount of expenses either related to distribution or promotion policies, which can ultimately have a positive effect on the objective side of quality of life. The objective aspect of quality of life is about fulfilling social and cultural needs depending on material sufficiency, social acceptance of the individual or physical health.

4 Discussion

Food as a concept and as a need is often multidisciplinary researched and published. It is linked to economic indicators that affect food consumption, such as household income and expenditure, developments and the level of consumer prices, etc. In the study Intelligent production management - progressive trends, a strong dependence of the development of the level of food expenditure on household income was statistically proven by regression and correlation analysis. Expenditures on food and non-alcoholic beverages account for the largest share of total expenditures, accounting for 19% (Majerník, et al. 2018). In the study Building food safety into the company culture: a look at Maple Leaf Foods, the authors Jespersen, Huffman focus on food safety and the introduction of sustainable food safety behaviour into the existing corporate culture. Decreased public confidence in the regulation and management of food safety in Europe and beyond and genetically modified foods have been addressed (e.g. Houghton et al., 2008), dioxins (Verbeke, 2001) and acrylamide (Marvin, 2009). Other authors have focused on finding and applying Hazard Analysis and Critical Control Points (HACCP) and Risk Analysis (RA) systems. The HACCP system is a systematic approach to the identification, evaluation and control of those steps in the field of food production that are crucial for product safety and is purposefully used in practice for the purpose of prevention, not control. (Luning, et al., 2002, van Asselt, et al. 2010).

From publicly available publication sources, the authors felt the causality of research, absence of published studies that would be devoted to finding a broader connection with the concept, nature, and possibly, the consequence of inappropriate consumer behaviour in the market of selected foods and meat. It is true that the OECD database offers the most comprehensive source of comparable statistics from different economic sectors in OECD countries. It is an essential tool for performing comparative analyses, but it is also necessary to use appropriate statistical mathematical methods, which are helpful in finding broader contexts and finding the causes of individual phenomena. The OECD has also published statistics on the health status of the population of OECD member countries in 2018. The online database of the publication "OECD Health Statistics 2018" is the most comprehensive source of comparable statistics on health status and health systems across OECD countries. Expenditure on health care increased in 2016 by an average of 3.4%, which is the highest rate since 2009, but still lower compared to the pre-crisis period. Health expenditure in OECD countries averaged 8.9% of GDP in 2016, which should remain unchanged in 2017. The highest health expenditure is in the US - up to 17.2% of GDP and the lowest in Turkey - only 4.2% GDP. In 2017, health care expenditures per capita should average $ 4069. This amount is about 70% higher than the amount that OECD countries allocate to the education of each population.

The knowledge and the results of the work, which have limits due to its scope, resulted in the formulation of conclusions, proposals and recommendations. The authors believe that they form an entity of scientific research that still needs to be further developed in space and time.

5 Conclusion

Based on the summarization and comparison of knowledge, it can be stated that, if the inhabitants of the Slovak Republic want to live up to the highest possible age, they should

prefer the consumption of game and limit or entirely avoid the consumption of pork. Based on the forecast from 2014 to 2020, the Slovak Republic will record a decrease in beef consumption by 113% and in game consumption an increase of 17.62%. The primary research of a representative sample of respondents shows that the Slovak population rarely buys game, but it is statistically proven that the frequency of purchase and consumption of this type of meat is welcome and healthiest in these conditions. In the Czech Republic, the population should consume pork and game, because on the basis of the forecast from 2014-2020, the Czech Republic had a change in game consumption by 9.99%. The people of Hungary should prefer the consumption of game and limit the consumption of pork. Based on the forecast from 2014 to 2020, Hungary had a change in game consumption by 1.5% and in 2020-2030 an increase in game consumption by 2.47%. In Poland, if people want to live up to an old age, they should prefer eating poultry and avoid eating game. Based on the forecast in 2014 to 2020, Poland recorded a change in game consumption, which fell by 39.08%, and in 2020-2030, game fell again by 107%. Suggestions and recommendations that should result in a change in consumer behaviour when eating meat.

In the case of Slovakia, with an increase in beef consumption by 1 kg, the average life expectancy will decrease by 0.25 years. If the consumption of pork increases by 1 kg, then the average life expectancy will decrease by 0.05 years. In the case of an increase in the consumption of poultry meat by 1 kg, the average life expectancy will decrease by 0.03 years and in the case of an increase in the consumption of game by 1 kg, the average life expectancy will increase by almost 1 year (0.79).

Taken into account Czech Republic, if beef consumption is increased by 1 kg, life expectancy will decrease by almost 1 year (0.98). If the consumption of pork increases by 1 kg, then the average life expectancy will increase by 0.26 years. If the consumption of poultry meat increases by 1 kg, then the average life expectancy will decrease by 0.38 years, and for wild game the average life expectancy will increase by 0.62 years.

By increasing the consumption of beef by 1 kg, the average life expectancy will be shortened by 0.26 years, in pork the average life expectancy will decrease by 0.03 years, the life expectancy will be extended by 0.01 year when poultry is consumed and by 0, 56 years of consuming beef in Hungary.

Finally, in the case of Poland, an increase in beef consumption by 1 kg will be reflected in a decrease in average life expectancy by 0.06years. Increased consumption of pork by 1 kg contributes to the extension of the average life expectancy by 0.04 years. Increased consumption of poultry meat by 1 kg, results in an increase in average life expectancy by 0.26 years. Higher consumption of game by 1 kg, contributes to the reduction of the average life expectancy by 0.74 years.

The Role of Video and Social Networks in Marketing Adoption Strategies

Renáta Bílková[1,*]

[1] University of Pardubice, Faculty of Economics and Administration, Studentská 84, 532 10 Pardubice, Czech Republic

Abstract

Research background: In the past decade, the popularity of social networks has accelerated marketing perceptions. Social networks bring new challenges and opportunities for marketers to reach their customers. One-way advertising communication became two-way; businesses are changing marketing strategies, shifting from advertising messages to building relationships with audiences. It is then up to the company to create such messages for its target audience that must be relevant to satisfy their demands and needs and to choose such marketing channels where they spend most of their time.

Purpose of the article: We need to think about where the target audiences are, what they are reading and what they are doing. Recently, more and more people are using their mobile phones not only as a communication device, but also as a place where they spend their free time. The purpose of this study is to examine how social networks and video marketing can help companies improve marketing adoption strategies, customer engagement, and business performance.

Methods: The study is based on scientific publications, statistics, and other relevant sources dealing with video marketing. For the purposes of the article and to obtain the target information, the data was collected using an online questionnaire survey technique applied to 260 students representing the generation of social networks.

Findings & Value added: The article describes the practical advantages of using video for marketing purposes and ideas for different types of video content, which help companies find an accurate marketing strategy and attract a new and loyal audience.

Keywords: *digital marketing strategy; social media; video marketing; content marketing*

JEL Classification: *M31; M37; L81*

1 Introduction

As the Internet has changed from a technological communication tool to a channel for customer relations and sales, companies have had to change their marketing strategies for their online presence. For the success and competitiveness of a company, it is crucial that its brand can be discovered in the virtual world. All businesses want to be as visible on the Internet as possible and to reach customers not only through computers but also via mobile phones.

Digital marketing is a wide range of channels that can be used to promote business interests to potential customers. There are many ways to manage digital marketing according to business needs and objectives. Especially in times of crisis and increased competition, companies focus on how to maximize their available marketing budget. The easiest way to reach consumers is by implementing user-centred approach marketing strategies. This strategy, called inbound marketing, focuses on creating a marketing style that people love. This means promoting companies through blogs, podcasts, videos, ebooks, electronic newsletters, white papers, SEO, social media marketing, and other content marketing methods. Inbound marketing means marketing activities that bring visitors in, earning the attention of consumers, making the business easy to be found, and also drawing customers to the website by generating stimulating content (Halligan, 2009).

Social media are one of the main drivers of today's website traffic. They have spread throughout the world and are an integral part of daily life for many people today. We currently live in a digital world and social networks are at the centre of this new reality. According to (Hootsuite and We are social, 2022), more than 4.7 billion people (59% of the world's population), of which 227 million are new users from the last 12 months, use social networks to communicate with others, share information, run, and manage a business, follow various brands and celebrities, capture what they do or how they feel. The average daily time spent using social networks is 2h 29m.

Therefore, this is a natural evolution of digitization of marketing efforts. For companies and brands, social media is becoming an integral part of their marketing activities and brand building and, as such, must be embedded in the development of any business or marketing strategy (Atherton, 2019; Li et al., 2021).

The purpose of this article is to present the main directions of modern digital marketing in the creation of digital content, when one of the most important factors is the understanding of customer behaviour and their preferences for spending their free time in the online environment.

For the competitiveness of companies in the age of globalization, it is very important that they create messages for their target group of customers that are relevant to satisfy their requirements and needs and that the company chooses marketing channels where their prospective customers spend most of their time.

2 Theoretical background

Getting found online by the right person, at the right time, is the key concept of a successful inbound marketing strategy (Halligan, 2009). The content needs to be useful, focused, clear, and compelling to the target audience. Whichever type of content you choose to create doesn't matter, what matters is that it is beneficial and meaningful. (Jefferson & Tanton, 2013). Content plays a major role in pulling people from one stage of the purchase funnel to another. This purchase funnel is defined as a series of contact points of various marketing channels and media through which customers go before, during, and after the purchase (Fishkin & Høgenhaven, 2013; Kranzbuhler et al., 2018; Lemon and Verhoef, 2016). Generating quality content requires observing the customer and their behaviours to be able

to meet their needs, because high-quality content is what creates value for customers, rather than merely promoting the company's products (Järvinen & Taiminen 2016). Therefore, the emphasis on creating quality content is crucial and creates another way to gain customers. Most consumer brands have social media profiles, and advertisers and marketers want to integrate social media into their digital strategies (Voorveld, 2019; Muninger et al., 2019).

There are many types of content that can be used by companies for their content marketing. The types of promotions are different depending on the products or services offered and the target customer. Digital content marketing consists of two broad activities, customer acquisition and customer optimization. Both are of fundamental importance to the bottom line of a company. Customer acquisition refers to activities that generate traffic – attract visitors to online properties; customer optimization means activities that improves user experience and converts more visitors into customers. The creation of purpose-oriented content is one of the most important parts of inbound marketing. The most prominent elements of digital inbound marketing are interactivity and engagement (Opreana & Vinerean, 2015).

The content marketing creation process starts with the attract stage of the purchase funnel. The goal of this phase is to attract the right people with valuable content that engages or creates a trusted advisor to solve their problem. Blogging, publishing content on social media and a well-optimized website make sure that the possible customer ends up finding your product or service (Fishkin & Høgenhaven, 2013; Lopes & Casais, 2022).

Marketers have several branding options in the social media landscape, including placing paid display advertising, participating in social media as a brand personality, developing customer engagement opportunities on social media, and publishing branded content (Ashley, 2015). Businesses can use social media marketing as an integral part of their marketing communications campaigns. Different platforms require contextualized contents since customer profiles are different on different platforms and the same content will not be efficient in different content communities (Lopes & Casais, 2022). The quality of content marketing on social media can be checked by an indicator of the engagement they feel with a company or brand – how people share their content and how they interact with it (Balio & Casais, 2021).

The role of format content, e.g. image, video, etc. can generate a different impact on user engagement behaviour. Video posts encourage users to actively engage with the fan page by sharing their opinions and comments on business posts, while photo content stimulates passive user engagement through likes (Shahbaznezhad & Rashidirad, 2021). Video production, particularly for the B2C context, has proven to be one of the most effective content marketing techniques (Lou et al., 2019).

In today's increasingly competitive market environment, it is very important to gain knowledge about customers, their perception of marketing content, which marketing channels are best to reach them, and what influences their buying attitudes. The objective is to improve marketing strategies, increase customer engagement, and business performance.

3 Research Methodology and Results

The basis of any good marketing strategy and the creation of quality content not only for social networks is to obtain as much information as possible about the target market, available marketing channels, knowledge about customers and their perception of marketing content.

The weakness of regularly published surveys is their limitation to the selection of the target group. These are mostly general surveys, and only sometimes with more detailed data, e.g., according to demographic parameters. For the purposes of this article, we prepared a questionnaire that focused on respondents' behaviour on social networks and

their content preferences. the data was collected using an online questionnaire survey technique applied to 260 students of the University of Pardubice. This target group represents the young generation, which we can also call the network generation. They are the key audience on social networks, which determines the future direction of the development of social networks. They tend to consume content on multiple platforms through multiple devices and are usually highly influenced by their social groups. Consequently, marketers should understand how these people consume information and how to reach them with appropriate marketing messages.

According to current statistical data published by Statista, 2022, there are 5.03 billion Internet users worldwide in 2022, of which 4.7 billion were social media users; mobile devices (excluding tablets) generated 58.99 percent of global website traffic. Smartphones now drive the overall increase in consumers' digital time and mobile is the fastest growing medium within digital marketing (Mulier, 2021).
Figure 1. Most used devices

Source: Hubspot (2022); AmiDigital (2022); own research

According to the 2022 Social Media Industry Report (Stelzner, 2022), 85% of marketers indicated that their social media efforts have generated more exposure for their businesses. As the second major benefit of social media, they point out increased traffic. In the same report, marketers declared Instagram and Facebook the best platform for developing loyal fans.

For the preferred social networks comparison, we only bring in data from the Czech Republic, because there are large differences in user preferences in particular countries. For example, the social network Reddit, so popular in the US, or Weibo, the most used social network in China, are almost unknown in the Czech Republic.
Figure 2. The most used social network in Czech Republic

Source: AmiDigital (2022); own research

YouTube and Facebook are consistently the most popular among social networks. However, the most dynamic Instagram is constantly catching up. TikTok and Snapchat, which influence content trends a lot, can become future stars (AmiDigital, 2022). Their popularity among the youngest and therefore most active users speaks in their favour This trend was also confirmed by our survey, as seen in Figure 2. The popularity of these networks inspires other competing networks. The content and formats used on it essentially affect trends on other networks, which take over the most popular content formats from them, such as the Stories format, which Instagram "stole" from Snapchat a few years ago.

According to a survey by AmiDigital (2022), visual content is the most popular among all user groups. Although posts with photos are the most frequently published content, short videos are growing in popularity. This is reflected in the expansion of formats such as Stories or Reels. Also, (Sedej, 2019) also highlights that video marketing is now one of the biggest opportunities to attract consumers in a real and authentic way because it can engage consumers' emotions and address their needs.

Video marketing is effective because it can quickly deliver more information in a short time and therefore better engage attention than just text or pictures. Video is quickly becoming the preferred tool for most marketers to connect with audiences and reach them. Each business uses video for a completely different goal, from increasing brand awareness, educate customers, and boosting SEO. It can be said that the video format is useful for all commercial objectives pursued by companies. Crestodina, (2018) points out the connection between the use of the video type and the first part of the marketing funnel. Figure 3 shows that people in different stages of awareness search for different places and different types of information and preferred different types of videos. While social media videos tend to attract attention, content-focused videos aim is to educate or explain certain topics and usually have a higher conversion effect.
Figure 3. Types of the video in Inbound stage of the marketing funnel

Source: Crestodina (2018)

Stelzner in his survey (Stelzner, 2022) asked marketers to select the single most important video format for their business. The result of this survey is shown below in Figure 4.
Figure 4. The most important video format for marketers

Source: Stelzner (2022)

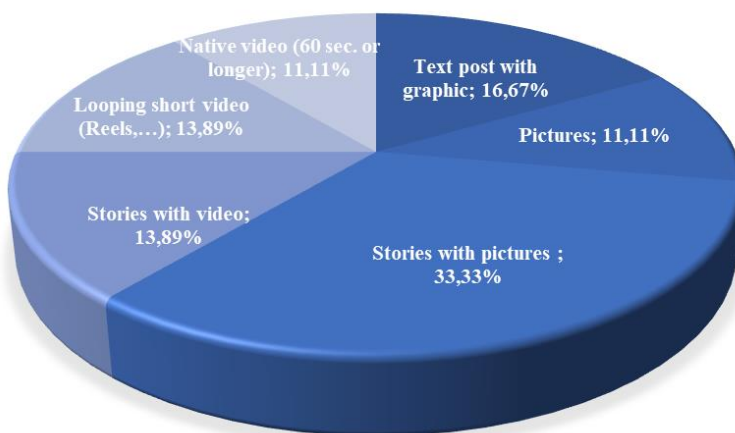
In accordance with this survey, we asked our respondents to indicate which content they prefer on social networks and where they have the highest engagement rate. The results show that 80% of our respondents from the selected network generation prefer purely visual content (i.e., pictures and video) which is corresponding with the AmiDigital (2022) survey. Almost 40% of respondents prefer video content over image posts. An interesting fact is that almost half of the respondents prefer the Stories format, content with a short expiration.


Figure 5. Preferred content on social networks

Source: own research

An interesting fact is that almost half of the respondents prefer the Stories format - content with a short expiration. For these posts, the quality of the content is very important, but the quality of the production is not that important. The adoption of "good enough" production quality leads to a massive amount of video content created ad-hoc on platforms such as Facebook, Instagram, Twitter, etc. Social media users explained that their preference for social media with short-form videos was due to convenience (LemonLight,

2021). This type of video is attractive and sharable, and many companies can easily execute it. The important thing is to post authentic content that people want to watch – content that can be simple, fun, up-to-date, and engaging. Plus, since video is dynamic, it grabs attention better than static images or walls of text.

Looping short-form video format like Reels is on the rise. According to many social media marketing experts, short videos are one of the best tools to take your business to the next level.

4 Conclusion

With the growth of the world's digital population, social media have become more and more widely used. Social networks are part of everyday life, and they continue to transform our global interaction, providing users with access to all kinds of information. Social media has changed the way marketers interact with consumers. It is very important for them to know where on this digital environment their audience is, what they are reading and doing there, and build a relationship with them.

This work has shown that the current young generation uses at least one social network daily. At the same time, we focused on the devices that are used to access the Internet and what kind of content published on social networks our respondents prefer. As well, our study confirmed the trends evident from the available statistical data. Reels (short-form videos) and Stories (visual content with a short expiration) are growing in popularity. Both formats, which recently appeared as news on the most widespread social networks Facebook, Instagram, Twitter, etc., were inspired by the young people's preferred networks TikTok and Snapchat. This is why we should monitor the behaviour and preferences of young generations, which affect future trends and direction for the development of digital marketing content, especially on social media marketing.

We believe that social media channels are a key component of any marketing initiative and video marketing is one of the most important channels to attract consumers. Their implementation in a company's digital marketing strategy can represent a great competitive advantage.

Abstract

Research background: 3D printing encompasses many forms of technologies and materials as 3D printing is being used in almost all industries. Currently, it's still unclear what impact additive manufacturing will have on globalization. Several trends are planned for as 3D printing increasingly permeates current manufacturing. Companies that had material shortages during the COVID-19 pandemic are gradually starting to use 3D printing options in their companies.

Purpose of the article: The main purpose of the contribution was to analyse the possibilities of using 3D printing in the manufacturing industry worldwide, and we conducted a questionnaire survey focused on the possibilities of using the technology procedures of 3D printing in the manufacturing industry in Slovakia.

Methods: In order to carry out the analysis, a questionnaire survey was carried out, the aim of which was to find out in which companies, areas and what is the application of 3D printing in Slovakia.

Findings & Value added: One of the main findings of the questionnaire survey was that 3D printing is primarily used for custom print production, which accounts for up to 48% of responses from the questionnaire survey. Companies do not produce a large number of products, but they have the opportunity to produce different variants, which is very close to 3D printing.

1 Introduction

Technologies, rapid progress, innovation, automation are very important from the point of view of globalization. From this point of view, the topic of using 3D printing in the manufacturing industry is very topical. The COVID pandemic has changed everyone's view

---

* Corresponding author: vladimira.binasova@fstroj.uniza.sk

of the future. Companies that had shortages of material during the crisis are gradually starting to use the possibilities of 3D printing in their companies.

A possible reason for the increase in interest in 3D technology is the missing components in companies, without which workers cannot continue to work and make final products. (Mani, et al., 2022), (Tan, et al., 2022), (Grznar, 2022). Missing components that are not supplied by suppliers as a result of the pandemic that has hit us can temporarily suspend the production of production lines in companies.

These missing components could be replaced through 3D printing. 3D printing objects are created using an additive process. In the process, the desired object is created by gradually applying the material layer by layer to the base plate (Lee, et al., 2017), (Lee and Chua, 2017). (Choo, et al., 2020). This technological process is the exact opposite of cutting, where we cut pieces using a cutter material. Unlike traditional manufacturing, 3D printing allows us to create complex shapes using a minimal amount of material.

Additive manufacturing processes include various technologies, including 3D printing technology. (Lu, et al., 2018), (Rakyta, 2022). This technology, which includes a number of methods capable of producing 3D products, uses computer software (CAD) in which we can design products according to our own imagination. The computer hardware has the task of directing the material so that it is deposited layer by layer in the desired geometric shapes.

We define 3D printing as an additive manufacturing process in which products are produced based on a digital design. 3D printing produces a final product identical to the digital model (Flynt, 2020) (Bubenik, 2022). Using this technology, it is possible to produce more complex objects in less time and at lower costs. Today's 3D printing innovations allow us to process small and specific components in detail. This technology provides us with precision, speed high-quality manufactured products. Modern 3D printing provides multiple possibilities for using the remaining material, thus avoiding unnecessary losses. (Wilson, 2020), (Day and Speers, 2020), (Sukalova and Stofkova, 2022).

The use of 3D printing in mass production has still not found its perfect application. The reason is insufficient automation of this process. Industrial enterprises are constantly moving forward and trying to automate their lines as much as possible. Companies invest more and more money in the implementation of additive manufacturing. It's only a matter of time before 3D printing catches the attention of the wider public on a much larger scale. (Butt, 2020.)

2 Methods

The following chapter is focused on the analysis of the possibility of using 3D printing in the manufacturing industry, which was realized using:
- worldwide survey focused on 3D technologies,
- questionnaire survey focused on the possibilities of using 3D printing in the manufacturing industry (subchapter 2.2) and its evaluation
- information obtained from the event - Spring roadshow of 3D printing and 3D scanning.

2.1 Worldwide survey focused on 3D technologies

In 2020, Admasys created an international survey aimed at the use of 3D printing in companies in the Czech Republic, Slovakia, Hungary and Romania (Formlabs Form 3B+). Analysing the survey, they found that businesses that decided to use this technology were definitely satisfied with the results. This survey also showed them a big change in the spread of 3D printing technology over the past two years in the Czech Republic (Figure 1).

Thanks to this company and their initiative, 3D printing has spread much more in the Czech Republic, even to larger one's industrial enterprises.

In the coming years, a significant increase in interest in additive technologies such as 3D printing is expected on the global market. An annual increase of 33% is estimated, which was also confirmed by the companies involved in the Admasys survey. Industrial enterprises see the prospect in this field and highlight the immediate possibility of printing on demand.
Figure 1. Comparison of the use of 3D printing in individual countries.

Source: author (2022)

We know that currently, the 3D printer is more advantageous for small-scale production. There is no need to make moulds and provide other special equipment. All necessary components can be printed on a printer. However, this cannot be said about mass production. The potential of using 3D printing in this production is currently focused more on smaller series with restrictions or the production of prototypes.

Automating 3D printing is not easy, despite the efforts to introduce large-volume printing into manufacturing industries, a human factor is still needed in its operation. The 3D printing production process requires manual steps such as turning on the printer, transferring files to the printer, inserting the appropriate material and finally starting. This procedure requires a lot of time but also the skills of the workers, and this causes the 3D printer not to be introduced into large-scale production.

2.2 Questionnaire survey focused on the possibilities of using 3D printing in the manufacturing industry

The subchapter contains a questionnaire survey, in which the effort was to find out information about the use of 3D printing in manufacturing companies throughout Slovakia. The questionnaire contains 14 questions, which are divided into three sections shown in Figure 2. 60 companies filled out the questionnaire.
Figure 2. Main areas of questionnaire survey.

Source: author (2022)

In the first section, the questions focus on the characteristics of the company. In enterprises, we asked about categorization according to the number of employees, i.e. whether they belong to the group of micro-enterprises, small enterprises, medium-sized enterprises or large enterprises. The second question refers to the type of production introduced in the enterprise. There are options for small series, large series, custom and continuous production.

In order to be able to evaluate in which area of industrial enterprises among the respondents 3D printing technology is used, we chose as another question the area of operation of the given enterprise. The most likely industries to choose from are engineering, automotive and others. After answering these questions, the questionnaire will let us go to the second section, to questions focused on the use of the 3D printer.

Section number two contains 8 questions. As the first and key question of the entire questionnaire, we asked if the company had purchased a 3D printer. The choice was Yes/No. We consider this question to be crucial, because if the respondent answered negatively, the questionnaire directed him to finish, i.e. send the answers.

The second question of the 3D printer use section asks about the reason for purchasing a 3D printer, we have 5 answers to choose from, and the last one is to write a different reason than those listed in the options above. The following question does not have a choice of options, but it is necessary to add a short answer to the question of what type and brand of 3D printer the company purchased.

Another question is focused on the material used in their printer, there are four options to choose from: plastic, resin, metal, and colour 3D printing technology. Since the 3D printer has many advantages, in the following question we aimed precisely at a few of them. We asked manufacturing companies which of the advantages we listed in the options convinced them to purchase a 3D printer. If none of the options is suitable, the last option is to write your own thought. The question that is next in the sequence determines the possibilities of using 3D printing and therefore whether the company uses it for the production of spare parts, the production of prototypes or in the production of components in development and research. Of course, there is also the possibility to add your own possibility of use in their company.

Question number 11 should find out whether the costs of production using a 3D printer are lower or higher than the costs of producing the same components without the help of 3D printing, i.e. in the traditional production. The final question of this section explores the possibility of using 3D printing in corporate departments. He is trying to find out in which department of the company they see the application of 3D printing, such as the TPV department, production, maintenance or others. The last section, also called the Conclusion, finds out whether the companies that participated in this survey are satisfied with the purchase of a 3D printer. He also analyses whether they want to expand 3D printing or other additive technology in their company in the future. This question should determine the interest of businesses in 3D printing and additive technologies and their expansion in the near future. The last question of the questionnaire is optional, so only those who want to fill it out. A link is written in it where we can contact their company if necessary.

3 Results

Summary of the possibilities of using 3D printing from a questionnaire survey:
- According to the survey, micro-businesses use 3D printing the most in terms of business size (1 to 9 employees). This category is represented by up to 41%. This confirms to us that, according to the number of employees, 3D printing is used the most in smaller companies.

- The questionnaire survey showed that 3D printing is primarily used for custom production. Custom production accounts for up to 48% of responses from the questionnaire survey (Figure 3). It is the so-called custom production. Enterprises do not produce many products but have hey do the possibility to produce different variants, which is very close to 3D printing.
Figure 3. The type of production.

Source: author (2022)

- The largest percentage of enterprises (Figure 4) that participated in the survey in the field of production (activity) belongs to the engineering industry (31.33%).
Figure 4. Main areas of questionnaire survey.

Source: author (2022)

- Up to 85% of the companies surveyed have purchased a 3D printer.
- The reasons for purchasing a 3D printer were special production, i.e. the sale of the device printers, due to the variety of shapes, printing spare parts for machines and equipment, individual printing according to your own design and others.
- The most frequently purchased printer brands in the survey were Prusa, Zotrax, Creality Ender or Markforged. Other brands were also mentioned here, for example, EOS, HP, Max Micron, Flyingbear, Trilab, Anycubic, Formlabs and more. There were several answers even such that it is their own production. One respondent stated that he printed the components on another printer and then assembled it to his liking ideas.
- According to the material point of view and the choice of filaments, most of these companies use plastic 3D printing technology (Figure 5). The reasons are its simple operation and unnecessary processing or other processing of the component.
Figure 5. Advantages of 3D printers.

- Low production costs have convinced businesses to buy this 3D printing technology and used it in their production (Figure 6).
Figure 6. Advantages of 3D printers.

- The companies involved in the survey use 3D printing technology in the largest amount 53% for the production of prototypes.
- When comparing the costs of traditional production and production using 3D printing, it was shown that up to 92% of companies have lower production costs thanks to 3D printing than they had before it is using.
- By analysing the questionnaire, we obtained information that companies see the use and application of 3D printing, especially in development and research.
- The question of satisfaction with the choice and use of 3D printing evaluated up to 98% of success and satisfaction with its functioning and production.
- Currently, 3D printing technology is not as widespread in businesses as we would like to be imagined. However, up to 90% of companies want to continue expanding additive technology in their productions.

4 Conclusions

The development of 3D printing brings constant new possibilities of use in companies and helps in many types of industries. Today, it is technology at a highly professional level, which is adapted to the needs of users. People's desire for environmental friendliness is reflected in the choice of aspects such as food, waste, energy and even the choice of production technologies. One of these technologies is 3D printing, which is currently considered highly ecological.

   The main goal of the contribution was to analyse the possibilities of using 3D printing in the manufacturing industry. We analysed the global situation of 3D printing in the manufacturing industries using a survey from Admasys. We created a questionnaire survey focused on the possibilities of using 3D printing in the manufacturing industry in Slovakia. The results of the conducted questionnaire survey showed in which companies and areas 3D printing is used and is widely used in practice. Thanks to participation in the event - Spring roadshow of 3D printing and 3D scanning, we obtained information for those interested in introducing 3D printing in their company. It discusses the current situation of 3D printing in the manufacturing industry but also focuses on its future direction and progress.

What effects will the advent of Industry 4.0 have on nations globally

Roman Blazek[1,*], and *Peter* Adamko[1]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: Industry 4.0 was first mentioned in 2013. This phrase encapsulates the effect that emerging technology will have on the nation's entire economy. These technologies have an impact on a wide range of fields that must adjust to the trend as it eventually transforms into Industry 5.0.

Purpose of the article: Industry 4.0 has an impact in several domains. In order to successfully implement Industry 4.0 over the world, the article's goal is to concentrate on the most heavily advertised areas.

Methods: A bibliographic analysis will be utilized to determine which areas are most impacted by the implementation of Industry 4.0. This analysis will assess through a map which areas should be the main emphasis to make the implementation as effective as possible.

Findings & Value added: Countries will be able to develop a strategy that will assist them to transition to Industry 4.0 more quickly by doing bibliographic analysis and determining which sectors are most influenced by the application of contemporary technology to the general functioning of global economies. Based on the findings, it can be stated that Industry 4.0 is not just concerned with business, but also with the general welfare of the populace because it also has an impact on Smart Cities.

1 Introduction

After a symposium in Germany in 2013, the phrase "Industry 4.0" started to be utilized. Lasi et al. (2014) they assert that this year marked a turning point since it started to discuss the digitalization of certain market categories. The goal of this digitalization was to reduce management, production, and management mistakes. Additionally, it was intended to help the company's departments come together (Xu et al., 2018), make individual operations more clear, make it easier to fix faults in specific parts, and free workers from physically

taxing manual labour that might cause a variety of health issues. It is a really smart concept to link artificial intelligence with societal governance. According to Zhong et al. (2017), Novak et al., (2021), Lawrence & Durana (2021), Wade & Vochozka (2021) artificial intelligence has the ability to quickly assess many options and select the one that would be most useful in the given circumstance. Additionally, it frees workers from a variety of administrative responsibilities that hinder their productivity. According to Yin and Yu (2022), businesses that are connected and structured in this way are able to produce a lot more items since they have fewer processes that divert employees' attention from their main duties.

2 Literature Review

According to Zhong et al. (2017), Industry 4.0, the next generation of business, promises greater industrial flexibility together with mass customisation, improved quality, and enhanced efficiency. With a quick time to market and superior quality, it lets businesses to overcome the challenges of creating an increasing number of customized items. According to authors Lee et al. (2014), today's Industry 4.0 production has networked machines that work together as a community. Ghobakhloo (2020) these developments need the use of forecasting techniques to systematically transform data into knowledge that explains uncertainty and helps decision-makers make better "informed" choices. According to authors Lu (2017), Hopkins & Siekelova (2021), Rogers & Kalinova (2021), Kovacova & Lăzăroiu (2021), Hawkins (2021), Hamilton (2021), Zvarikova et al., (2021), Nica & Stehel (2021), Riley et al., (2021) Internet of Things (IoT), Cyber Physical Systems (CPS), Information and Communication Technology (ICT), Enterprise Architecture (EA), and Enterprise Integration are all strongly connected to Industry 4.0. (EI). A systematic and thorough assessment of the most recent research on Industry 4.0 is not yet accessible, even though it is an active field of study. The primary motivation behind doing the study you are currently reading was this research. Industry 4.0, also known as "intelligent manufacturing," "industrial internet," or "integrated industry," was coined by authors (Hofmann and Rusch, 2017). It is a hotly debated concept that has the potential to change entire industries by altering how products are created, produced, delivered, and paid for. Industry 4.0, often known as "Smart Manufacturing," is a recent development in the widespread application of information and communication technology in manufacturing processes that provides a preview of how the manufacturing industry will develop over the next several decades (Siqueira & Devis, 2021, Grant, 2021). Industrial Revolution 4.0 (IR 4.0), according to the authors Cheah et al. (2020), presents a chance to boost the effectiveness of solid waste management through the use of digital and mechanical applications, effective waste elimination, recovery, and reuse.

3 Materials and Methods

Collecting as much data as possible that will be useful and have a high volume of data will produce extremely accurate findings is important to achieve the objectives that were stated in the previous section of the article. This led to the decision to choose articles from the Web of Science collection that best represented the specific Industry 4.0 topic. The VosViewer tool was used to examine the more than 14,400 articles that were found once the keyword was picked. This produced a bibliographic map that was separated into clusters that further described the topic, in this instance Industry 4.0.

4 Results and Discussion

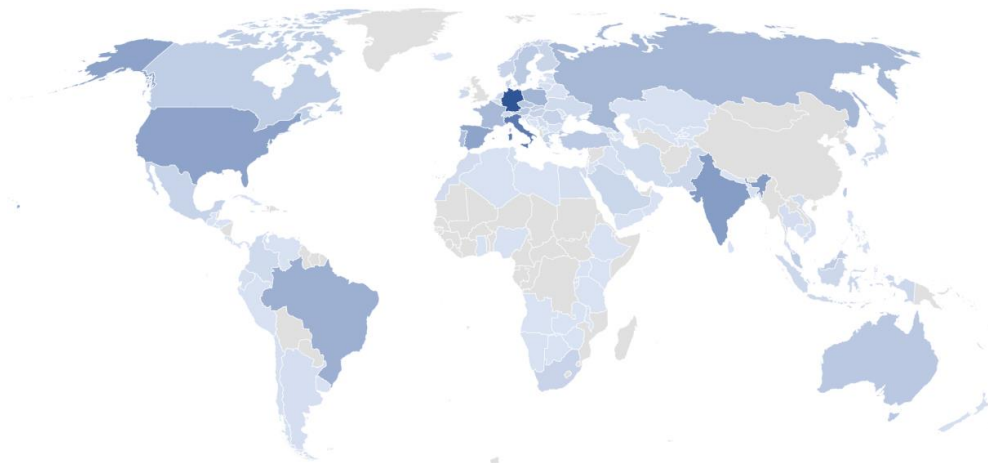
Since 2013, a growing number of scientists have begun to address the topic of Industry 4.0, working to enhance its general framework and so raise the tool's contribution to both business and personal well-being (Olesn and Tomlin, 2020). In an effort to address the various issues that may arise when using this tool, as well as to bring the use of this apparatus closer to eradicating errors and enhancing the overall position of the company in competitiveness, the following figure captures the countries that contribute the most to the improvement of Industry 4.0. As a result, some of the problems that prevent businesses from progressing will be resolved, and fewer checks will require the time of employees who may alternatively devote themselves to the success of the business. Because of this, there is now equal competition between firms that primarily focuses on factors like quality, pricing, marketing, and services. According to Neumann et al. (2022), one of the primary drivers of Industry 5.0 is the strain and demands that the quick technical advances of Industry 4.0 are placing on those who work in automation. Particularly, the creation of automation software for mechatronic systems is getting more and more difficult since high-quality and maintainable software need both domain expertise and programming abilities (Popescu et al., 2021).


Figure 6. Map of nations producing content on Industry 4.0

Source: own processing according to Web of Science (2022)

The major contributors to this problem are Germany, Italy and China. For instance, India, the United States, Spain, England, Brazil, Poland, Slovakia, Czech Republic and other nations fall into the category of nations that create less articles than the top group. Another category includes nations like Saudi Arabia, the Netherlands, Finland, Denmark etc. Countries like Venezuela, Lebanon, Cyprus, Malta, Palestine, and others are included in the last group.

Table 1. The number of nations making the biggest contributions to the problem

	> 1,000	1,000 < > 200	200 < > 20	20 >
Amount	3	25	44	58

Source: own research

The phrase "industry 4.0" is frequently used, but it is increasingly morphing into "industry 5.0," which is also being discussed. Industry 5.0 is a relatively new idea, and in

order to implement it in a high-quality and accurate manner, individuals must be able to comprehend the substance and meaning of Industry 4.0. The writers of articles, research papers, and monographs examine a variety of Industry 4.0 issues, dangers, possibilities, and advantages. They will then produce a piece of useful literature that clarifies the many aspects of Industry 4.0 for readers all across the world.

Table 2. A summary of the procedures in the provided article

The search term that was entered	Monitored timeframe	Source lookup	Amount of articles	Looking through	Program
Industry 4.0	2012-2022	Web of Science™	> 14,400	Bibliometric Analysis	VosViewer

Source: own research

As a result, this article also covers the key components of the Industry 4.0 tool, which has emerged through time as the foundation of the entire system and has its roots in 2013. This examination of the word "Industry 4.0" was also done using bibliographic analysis, which was also used by the authors Hlawiczka et al. (2021) in their study. The following table of procedures was created in order to obtain the specified outcome, which is depicted in Figure 2, and to satisfy the proper classification of keywords.

Figure 7. Key words of the phrase "Industry 4.0" as analysed by the literature

Source: own research

According to bibliographical study, the most common keywords used when writing articles about Industry 4.0 include items like the *Internet of Things*, *Artificial Intelligence*, *Innovation*, and the *Future*. Each of these keywords is composed of additional components (keywords), which when combined provide the Industry 4.0 tool its overall orientation. These outcomes were attained using a compilation of all articles published in the Web of Science database. When generating a bibliographic analysis, researchers must employ as many papers as they can in order to obtain pertinent data. This requirement was satisfied, and the VosViewer software showed the key phrases that best describe the subject of the study.

Figure 8. Overview of the organizations who publish on Industry 4.0

Source: own research

A bibliographic analysis of companies that publish material on Industry 4.0 was subsequently produced. Organizations from V4 are also represented, as demonstrated by their participation in 1,468 publications to date.

5 Conclusions

The goal of this scientific contribution is to compile a bibliographic study of the Industry 4.0 idea. It was crucial to concentrate on this research so that scientific as well as technical and other authors, employees, or executives could understand Industry 4.0 as a help that can guide their company to better results. Industry 4.0 is a very interesting concept that has its roots in 2013 and has many advantages that benefit companies, competitiveness, and also workers in companies. Despite the fact that many individuals are familiar with the term "Industry 4.0", many have trouble understanding the specific problem at hand. Whether it is a broad grasp of Industry 4.0 or its subordinate keywords that complete the entire, the article refers to keywords and their lower levels of keywords that build the investigated idea and help the interested individual find the proper route in the provided issue. The categorization of individual terms into clusters may be seen in the following bibliographic analysis. This article can be used as a "springboard" for other writers as well as for a more in-depth analysis of certain aspects of Industry 4.0.

The Globalization Process' Impact on the Natural Environment

Dumitru Alexandru Bodislav[1,*], *Florina* Bran[1], Raluca Iuliana Georgescu[1], and *Victor Adrian* Troacă[1]

[1] Bucharest University of Economic Studies, Romană Square, no. 6, district 1, Bucharest, Romania

Abstract

Research background: Faced with the complexity and generosity of nature, man must orient himself towards respect in connection to the natural world. The primacy of the natural environment must be reconsidered by man. Our survival relies on our transformation, not the surroundings. In the era of globalization, many of the leaders of highly industrialized nations face sovereign disdain.

Purpose of the article: In light of these stipulations, the purpose of this paper is to examine the impact of the globalization process on the natural environment from the standpoint of value theory, recognizing that the value-utility theory attempted to replace working time with a more adequate physical support, but failed to explain differences in product value.

Methods: In all instances, the study that led to these axioms cantered on how the market disclosed the value in the form of exchange value.

Findings & Value added: The environment may be reflected in a company's financial sheet as land, in its important contribution via the low entropy represented by the inherent potential of minerals and raw materials, as well as in the uncountable goods: water, air, light, and solar heat. Typically, they are considered among the positive consequences of production and consumption.

Keywords: *globalization; sustainable development; growth; environment*

JEL Classification: *A11; A14; B16*

1 Introduction

The environment is present in the company's financial sheet, represented by land, in its important contribution via the low entropy represented by the natural potential of minerals and raw materials, as well as in the uncountable goods: water, air, light, and solar heat (Dima et al., 2020). These are among the positive outcomes of the production and consuming processes (Bran et al., 2019).

---

[*] Corresponding author: alex.bodislav@ase.ro

Given the immense potential that exists in nature, the contribution of the environment to the economic process of the enterprise is highlighted as follows: the natural potential in the form of substance, energy, and information is brought into the enterprise through extraction, transport, and research energy in order to be used appropriately (Negescu Oancea, et al., 2019).

2 Current environmental condition – methodological analysis

The present status of the soil relates to the quality of the soil, water, and air in the region, as well as whether or not the business has technologies that use these environmental components. In this instance, the corporation must handle meteorological and research services of water and air quality, as well as geologists, soil scientists, and seismologists (Rădulescu et al., 2018).

In order to prevent legal and financial repercussions, it is necessary to analyse the ecological constraints placed on the activity area and beyond. This information determines establishment - development choices, as well as production decisions (Alpopi et al., 2018). In addition, they will describe the scale and organization of the consuming process.

At the company level, the consumption process aimed at recovering the environment is only partly addressed. The majority of it is for the firm, with financial contributions from the people and other businesses (Jianu et al., 2019).

The firm coordinates the following environmental activities: filtration, water treatment, garbage disposal, and regulated waste disposal facilities to decrease environmental contamination. These are investment-type endeavors. Scientific research efforts involving the redesign of technology and goods to minimize consumption of natural resources and harmful waste. (Bodislav et al., 2019).

Activities to repair the environment of the enterprise and its immediate surroundings, as well as remediation of ecological catastrophes caused by the company. These are transactions involving investments and financial payments. Another activity is the typical contribution to centralized ecological efforts via the payment of taxes, fines, and taxes (Angheluta et al., 2019).

2.1 The occurrence of value

The totality of the traits that give an item, a person, or a phenomena its price is its value. Value may also be interpreted as significance, price, and worth (Shevcenko, et al., 2016).

The value as a concept is defined in DEX as: "Acquisition of certain things, facts, ideas, and phenomena to correspond to the social needs and ideals generated by them; the sum of qualities that give value to an object, a being, or a phenomenon that is significant, valuable, worthy of appreciation, and esteem."

Aristotle defined value in terms of physical, mental, and moral or spiritual requirements, recognizing in economic value, exchange value, and use value: "The use of every object is of two types, and in both situations the work functions as such, but in different ways: one use is its own - as a utility, and the other... as a means of exchange (politics)."

Since ancient times, there have evolved two major orientations for defining value: value = usefulness and value = labour. In the first instance, the production procedure and producer's function predominated. In the second instance, the consumer process and consumer role gained prominence.

In all instances, the study that led to these axioms cantered on how the market disclosed the value in the form of exchange value (Ozalp, et al., 2018).

This acceptance allows for four forms of value. The direct value, which expresses the benefit obtained by the user, the indirect value, which expresses the benefit of an indirect

consumer, the optional value, which expresses the benefit felt by a consumer when he knows that a particular ecosystem will be preserved, and the value of existence, which expresses the benefit felt by the existence, but not the recovery, of certain ecosystems, resources, and landscapes. The entire economic value would equal the sum of these four values.

2.1.1 The process of acquiring value

The value is the consequence of the changes that occur within human-driven economic activities such as production, distribution, trade, and consumption. Human activity that enters the realm of the economy is related with the actions of individuals who are a part of systems such as the family, company, national economy, global economy, and cosmic economy (Waldron, et al., 2016). All of these systems include the human life system. They are in the dynamic states of production, distribution-exchange, and consumption, influenced by both internal and external influences.

The systems of the economy, society, and natural environment are accountable for the acquisition and management of value. Economic processes are externalized and manifest as economic, social, biological, chemical, and physical phenomena.

The complicated nature of the economic phenomena is a result of the inclusion of all these occurrences. In the form of the economic phenomenon of value, the system for acquiring and managing value contains the same sorts of occurrences.

In the history of economics, two approaches to defining value have been emphasized: the theory of value based on effort (TVM) and the theory of value based on utility (TVU).

According to the labor-value theory, value is produced throughout the production process, and its physical foundation is the length of time spent working (social time required). Several explanations for the creation of value have been offered in relation to this notion. Karl Marx believed that anything is valuable if it materializes human work.

Adam Smith believes that labour is the sole source of value and that human activity generates the quantity of products consumed annually, while Turgot views work as a manifestation of the degree of regard that man has for the many objects of his wishes.

The idea was established during a time when the technology was underdeveloped and the issue was to fulfil the requirements of a rising population (Schotter et al., 2017).

The value-utility hypothesis has attempted to substitute appropriate physical support for working time. This idea fails to explain the disparities in price between various items. The water-diamond conundrum is the most well-known paradox (Kohlhase, et al., 2020). The notion of rarity was used to describe this scenario.

3 Operations of the mechanism for generating value

In the mechanism for acquiring value, the economic processes of production and consumption, as well as the natural processes from the surrounding environment and the processes unique to social life, are significant. There are two sorts of processes inside the system for acquiring value: main and complicated.

The first fundamental process is transformation. Referring to the scenario of the Great Explosion, the original explosion was a process of change that resulted in the organization of matter and the emergence of low entropy.

Conservation is the second fundamental process. The particles and radiations created by the initial process have joined the conservation process of these main products as stable matter structures: substance, free energy, and information.

Observations of natural events allow us to propose the existence of a third main process, transfer. Through the transfer, the results of the previous two processes are shifted in space and time, becoming outputs for one system and inputs for another.

The first complicated process occurred when the equilibrium system of the universe acquired a dynamic state. The massive explosion converted the pure energy into particles and radiation, which were maintained as matter, free energy, and information. These have been transmitted over space and time, becoming training system raw materials.

Similar to the first complex process, the second complex process employs the three fundamental processes to create complex structures. Thus, this low entropy is perpetuated in material structure, motion, forces, and high entropy. These outcomes are the services that will be conveyed over time and space.

The third complicated process concludes the Universe's cycle. Systems that are far from equilibrium and those that are near to equilibrium are brought to equilibrium. The structural systems of nature are translated to a transformation process involving a complicated process (the Great Implosion). The transformation results in the conservation of pure energy, which is transported over space and time.

In conclusion, the fundamental processes and complicated processes unique to the general system of Nature are also present in the systems engaged in the mechanism for gaining and managing value in the following forms: the production process, the consuming process, and the liquidation process.

The dynamic states into which all natural systems (environment, society, economy) enter are identical: consumption, production, and dissolution. These complicated processes include, in varying proportions, the fundamental processes of transformation, conservation, and transfer.

4 Discussion and conclusion

In the era of globalization, many leaders of highly developed nations approach abnormalities in nature with sovereign disdain because they fail to see nature's actual depth. With such a perspective, it is not unexpected that the West has achieved unprecedented dominance over the natural environment and irresponsible manipulation. And the worldwide appreciation for these accomplishments is another threat to the life of the sphere that develops from the spread of this aggressive and self-centred approach to abandoning humanity's relationships with the natural environment. (Serban, 2013). In his study on economic worth, the late university professor Paul Bran said that the environment's function and size must be revaluated after its gradual demise. The notion of man as an escape from nature explains his persistent desire to be liberated from the constraints of natural circumstances. Paul Bran (2002) noted that, as a result of man's drive for independence from nature, he has succeeded in constructing a highly complex living environment, as seen by his dynamic heterogeneity (Habersang et al, 2018).

Not only the natural environment, but also the altered one, gets anthropomorphized. Continuous anthropization of the environment. Man is the creator of more complex artifacts that often degrade nature by contaminating it with byproducts of production and consumption. The human environment is very complicated. We do not know whether I was a part of a worldwide plot; yet, the guy examines the economic and ecological dimensions of governance.

The economy now has no cure. A first answer may be a new paradigm of ecological wisdom's significance. Believe the reality of human activity on a global and planetary scale, but don't employ the "oikos" property (the home of life) and don't consider it to be so magnificent that one day, nature's destructive forces will give it wings. created. Man does not need to prove that he can survive without other trophic networks. Everything has a

beginning, therefore we must refrain from self-destruction and allow nature to flourish so that we, too, may survive.

In the era of globalization as it relates to the development of phenomena, too few people comprehended that the 20th century shattered value scenarios. By value mechanism, we imply the intimate relationship between human civilization and the nature of the Earth's sphere.

Every human activity has an immediate effect on the natural environment. Our existence is contingent on our capacity to alter ourselves, rather than the environment. In the present day, governments must act not on the basis of false scenarios, but on the basis of an understanding that ignorance of the rules controlling the existence and operation of the industrial realm makes it difficult to devise innovative solutions to issues. Let us evaluate the ecology and spirituality of the world while it is still possible.

Abstract

Research background: The global nature of communication platforms is due to the fact that they are seen as a way to overcome state-controlled media and content. The current era is characterized by a high degree of polarization of society and an enormous increase in intolerance. Radical views are supported by the targeted presentation of minority views, social networks are perceived as a balancing force for less important individuals.
Purpose of the article: The purpose of the contribution was to find and compare research conclusions related to social networks and their global social significance, especially in the context of manipulating the opinions of individuals and groups. We also confront these conclusions with the frequency of occurrences of key words in media and scientific publications.
Methods: Heuristics and a comparison of the conclusions of available sources and subsequent synthesis were used for the contribution. At the same time, extreme and false information in the digital platforms' environment was mapped and confronted with a confrontation with the dynamics of information dissemination.
Findings and added value: The research conclusions and comparison with other sources confirm the strong radicalization of society and the increasing intolerance in society. Social networks have contributed in no small measure to this radicalization, mainly thanks to anonymity, but also, especially recently, in the form of targeted provocations and forgeries. The added value of the research is the heuristics performed on the ProQust portal and in the Scholarly Journals databases.

Keywords: g*lobalization; hoax; hate; social networks; Facebook*

JEL Classification: *F68; L86; M38*

1 Introduction

Currently, it may appear that globalization processes are dampened, especially as a result of the pandemic process and the intensification of the global bipolarity process, which is a consequence of the Russia-Ukraine conflict and the struggle for energy resources. This

trend is visible above all in economic processes. Economic globalization is a historical process, the result of human innovation and technological progress. An integral, often overlooked aspect of globalization is the exchange of information, along with trade, movement of people, and movement of capital. Therefore, the multiplier effect of technological progress and the spread of knowledge across international borders is also an essential factor in current globalization processes. Subsequently, we can understand globalization as a form of sharing ideas and opinions. It is therefore evident that, in addition to the integration of economic processes, there may also be a globalization of authorities interest, transnational interests conditioned by the globalization of information processes. It can be stated that these processes are currently growing into a disinformation form, which is a typical element of the globalization concept of information dissemination. These processes are technologically supported, in particular, by the sharp increase in the spread of information through transnational social network platforms and the implementation of artificial intelligence in these processes. To understand the possible contradiction in the concept of the meaningful content of information that is disseminated through these networks, it is necessary to realize that anonymity, depersonalization of the confrontation and, in particular, the subjective interpretation of value criteria and the inability to define the values (moral, social, emotional, etc.) of humanity play a significant role here, different cultures and individuals. It is obvious that the discussion about the truth of the information is irrelevant, precisely because of subjective perception, similarly to the irrelevant discussion about truth and justice. However, it is possible to identify and discuss phenomena that are evoked by the current degree of globalization of information and the degree of anonymity, especially phenomena that lead to questioning the discussed content of the information or questioning the credibility of the source. At present, these phenomena can be traced to an increase in intolerance, aggressiveness, questioning of value standards, or reversal of the informational value of statements or provocations. For these reasons, the value of information and disinformation on social networks cannot be identified and quantified, as they are determined by subjective perception, worldview, belonging to social class and social status, social and political environment, and the ability to form one's own opinion (moral and socioeconomic factors). Therefore, only the use of information marketing means can be discussed, not the value measure. Even if social networks are not subject to standard forms of marketing and management, it can be stated that certain characteristic features of these fields are manifested in communication on these networks. In particular, networks are characterized by operator censorship, group policies and censorship, and targeted messages with advertising content. However, this advertising content is not only the supply and demand of goods and services, it is to an increasing extent mainly the paid promotion of purpose-oriented information, comments on social and societal phenomena, and economic problems (social marketing). In order to understand the handling of information content, it is also necessary to realize that we are dealing with Information Management (a sub-field of management), which has the task of standardizing procedures and processes in the handling of information, including the management and distribution of information to one or more users. We can talk about knowledge management from the point of view of managing human activity in general, based on the use of knowledge that effectively connects the bearer of knowledge with those who need the knowledge, by transforming personal (mostly hidden or tacit) knowledge into organizational (mostly explicit) or formal knowledge, in the form of partially anonymous communication, engaging in discussion in a defined knowledge environment and sharing opinions, thoughts, and ideas.

In essence, social networks are carriers of two basic levels of information work. The first level is the previously mentioned level of information and knowledge management, in which the globalization character is manifested and the targeted influence of recipients with

the distributed content of such information, which aims to influence the thinking of a specific community according to the requirements of the distribution source. The second level is the targeted sabotage and diversion of disseminated information, the bearers of which are mainly supporters of different ideological views, often purposefully manipulated and influenced by the first level (management). The aim of the research was to identify the frequency of phenomena that can be intentionally and purposefully used for the manipulation of information, to identify the current level of information manipulation in the environment of social networks, and to identify the social and societal distortions that can result from the manipulation of information on social networks, especially aggressiveness, intolerance, hatred, and chauvinism.

2 Literature revue

Prior to actual analysis, heuristics were performed based on available studies. O'Brien, & Alsmadi (2021), emphasize that: "...Just talking about this ever-shifting landscape is confusing, with terms like "misinformation," "disinformation" and "hoax" getting mixed up with buzzwords like "fake news"...", for this reason we distinguish between these terms according to the systematization of these authors. The fact that this is a truly global issue is proven by many studies, for example Barcelos et al. (2021) identified, based on information about Covid 19 available on social networks, that 20.1% of fake news related to politics, 19.5% related to epidemiology and relevant statistics on the spread of the pandemic. Matamoros-Fernandez & Farkas (2021) also state that social media dominates the socio-political environment in almost all corners of the world. The authors point out that new and old racist practices are increasingly taking place on these platforms. A typical example is abuse in the form of reliance on social media as a primary source of news in conjunction with support for racial politics (Lajevardi et al., 2022). Ndahinda & Mugabe (2022) mention specific cases where defamation (denigration) on social networks extend from global to local areas at the level of genocidal processes: "These self-reinforcing networks spread inflammatory nativist discourses, anti-Tutsi sentiments, dehumanizing language and calls for genocide". If social marketing and management were mentioned in the introduction as a form of globalization of the content of social networks, it is confirmed that hate speech appears as part of political activism on social networks (Melo Filho et al., 2022).

However, the targeted influence on the younger (adolescent) population is also starting to become a fundamental problem. Increasingly, there is a specific feature of social networks referred to as "cyberbullying" (Thun et al., 2022). This can be a serious problem in the future, because aggressive adolescents can be recruited into the core of social groups with antisocial behaviour. If we are dealing with methods suitable for analysing social networks, we can state that "hate speech on online social media platforms is now at a level that has been considered a serious concern by governments, media outlets, and scientists, especially because it is easily spread , promoting harm to individuals and society, and made it virtually impossible to tackle using just human analysis" (Nascimento et al., 2022). As very suitable for analysing data and facts that are widely disseminated through social media shows, analytical descriptive research appears to be (Lekik et al., 2020). In their study, Wani & Jabin (2022) tried to show the possibilities of comparative tools for these identifications. The previously mentioned global forms of content manipulation highly count on, and even encourage, this form of amoral behaviour, which can be traced to relatively little (if any) accountability of social network providers or network group administrators for fake profiles. The authors use standard cluster analysis based on user profile information to detect links between profiles and to identify fake profiles to detect suspicious links within user communities. A qualitatively higher level of analysis consists

of morphological analyses, statistically significant differences between classes found in fake and real news articles were used by Kapusta et al. (2020). Due to the dynamic development of social networks, it is difficult to apply longitudinal analysis methods; there are studies using this approach (Shin, 2022), even if the study compares values at only two time points, the research conclusions prove that communication in social networks is primarily tied with the circle of friends and social background, and for a better understanding of the influence of the environment, it is necessary to expand the research by examining social relationships outside the framework of friends. In addition to identifying profiles, it is also necessary to identify comments, currently there is a significant increase not only in false information, but especially in hateful comments, referred to as cyber-aggressive comments. Detection of these social media comments using machine learning and text mining was performed by Rasel et al. (2018). The proliferation of aggressive tweets, statuses, and comments on the social networks is gradually increasing. People use social media as a virtual platform to troll, blame, blaspheme, and slander each other. These activities spread hatred between race, religion, etc. Therefore, these comments should be identified and blocked on social media. An analysis through descriptive metrics of scholarly production on hate speech and social media and an exploration of the interdisciplinarity of these approaches was conducted by Ramirez-Garcia et al. (2022) in a bibliometric study based on works indexed in the Scopus database related to the binomial "hate speech" and "social media" for the period 2001 to 2020. A similar descriptive metric based on the occurrence of characteristic bigrams (two words) was carried out by Rashid MMO, (2022) who processed 3,200,747 Facebook comments and identified the frequency of expressions labelled as "toxic slander". A rather fundamental starting point can be found in a study published by Olaniran (2020), the author examines how social media has become a platform for fake news and propaganda that influences a certain audience towards a certain way of thinking. In particular, it is an alarming fact that social networks such as Twitter, Facebook, and Google have the potential to change civic engagement and thereby essentially distort democracy by influencing individuals towards a certain way of thinking. In this author's study, there are more than 50 references to sources that can also serve as starting points for similar research and that confirm that social media is currently a globalizing tool, expanding the opinion reach of a few like-minded individuals in a way that shapes policies for societies and nations as a whole. An important feature of social networks is the manipulation of empathies, especially the manipulation of feelings in the form of purposefully emotionally distorted information, by subverting feelings, changing the ability to recognize and understand emotions experienced by individuals and groups in the form of hiding or amplifying emotional stimuli. In the context of global influences, he published the results of four studies by Santos et al. (2022), where, based on research on empathy in intra-party communication and communication between parties (which can be compared to communication within/outside the group in a social network environment), he identifies, among other things, specific tendencies in manipulation (for example, the effort to dialogue is labelled as weakness and concession, or the bearer of the effort to dialogue is labelled as an agent of a group with a different opinion, or as a collaborator). Therefore, many authors openly point to the need to identify disinformation links and targeted fictitious tools (fake profiles, false information, targeted forwarding and mass forwarding of information, etc.).

3 Methods and data

The actual method consisted of identifying the occurrence of publication outputs based on a combination of keywords in the Proquest database. Keywords were compared according to their occurrence in the entire database and then according to their occurrence in

professional scientific journals. The data was mined in an interval of three consecutive years, then the total value was determined. The keyword database was a combination of social platform affiliation (Facebook, social networks, social media). Furthermore, the occurrences of terms related to misinformation and intolerance in the social media environment ("hoax", "hate, "populism", "anonymity") were investigated. The identification of the monitored terms was subsequently carried out in the context of the link to the keywords "globalization" and "analysis". Following globalization trends, the occurrences of the terms "marketing" and "management" were also investigated in connection with the frequency of the term "globalization" and the occurrence of the relevant type of misinformation. To finalize the obtained data, MS Excel tools were used, in particular, statistical function, contingency tables and contingency charts were used. Based on publication data in scientific journals, a percentage of scientific interest was identified. The data were normalized to the interval <0.1>, whereby the maximum detected value for each combination was transformed to the value "1", the value "0" was given as a real zero value. For individual combinations of keywords, the increase and dynamics of the frequency of individual occurrences of keywords were identified using the SLOPE function (1). This function returns the direction of the regression line through the specified points in the y_array and x_array regions. The slope is the vertical distance divided by the horizontal distance between two points on the line and expresses the rate of change along the regression line.

$$SLOPE(known\_y's, known\_x's) \tag{1}$$

where "known_x's" is the sequence of years between which the increase/decrease of values is observed, "known_y's" are the observed values of frequency of occurrence for individual combinations of keywords. The SLOPE function calculates the slope of the regression curve based on formula (2). A linear function (straight line) was used as a regression curve. The values of the last three years were used as data points to determine the current trend; the data intervals for determining the frequency are from September 25 of the previous year to September 24 of the current year; the data is based on the update given by the maximum possible times deadline available for data collection.

$$b = \frac{\sum(x-\bar{x})(y-\bar{y})}{\sum(x-\bar{x})^2} \tag{2}$$

On the basis of the slope, the dynamics of the increase in the value of the frequency of occurrence of the relevant combination in the last three years is determined. Using the direction and the intersection with the Y-axis (INTERCEPT function (3)), the relative distance of the maximum value on the x-axis can then be calculated by the direction shape of the line (4), which identifies the general dynamics over the entire period in which the given combination of key terms can be observed, it indicates, how long the relevant combination of key terms would take to reach the value of the grand total at the current growth rate.

$$a = INTERCEPT(known\_y's, known\_x's) = \bar{y} - \frac{\sum(x-\bar{x})(y-\bar{y})}{\sum(x-\bar{x})^2}\bar{x} = \bar{y} - SLOPE()\bar{x} \tag{3}$$

$$x = = \frac{y-INTERCEPT()}{SLOPE()} \tag{4}$$

4 Results and Discussions

Based on the analyses, it was found that in the Proquest database, the term "social media" (635662 occurrences) is most often represented in the context of the analysed keywords, followed by the term "social networks" (500852) and "globalization" (98433). In the

scientific literature, these terms were mentioned in 90.17% of the total occurrences, 84.07% and 83.06% respectively, the combination "analysis globalization" (83.97%) had a larger percentage share than the term "globalization". If we compare the occurrence in the last year, then the term "Facebook" is in third place in terms of frequency ("social media" - 96756x, "social networks" - 71957x, "Facebook" - 9520x", "globalization" - 8734x). The percentage order remained the same as for the overall values. In the discussion, it is necessary to return to the original nature of social networks, they are a democratic environment for alternative information sharing, which was originally intended to serve as a counterpoint to state-regulated media. Unfortunately, the anonymity and distortion of the meaning of "freedom of expression" creates fertile ground for ideological and political activism that can sometimes fuel violent hateful debates that turn these environments into dangerous and toxic places (Melo Filho et al., 2022). The fact that peer-to-peer structures of social media platforms shape public discourse and increase the likelihood that citizens will be exposed to unregulated, false and harmful content is quite often pointed out in the discussion (Lajevardi et al., 2022). Building on this discussion about freedom of expression, we examined the occurrence of information sources related to the terms "hoax", "globalization" and "anonymity". The term "anonymity" appeared on the "Facebook" platform in 1,173 cases, "hoax" in 843. In "social networks" the frequency was 3,925 and 3,258, "social media" 4,230 and 4,023. It is evident that restrictions on Facebook lead to a smaller proportion of the term "hoax". Furthermore, the term "anonymity" was linked to the term "hate" in 933 cases, the term "hoax" was then linked to "populism and hate" in 30 cases.

Despite the fact that social networks such as YouTube, Facebook, and Twitter have internal regulatory policies regarding hate speech and have signed a Code of Conduct for the Regulation of Unlawful Hate Speech with the European Commission (Alkiviadou, 2019), studies on social networks agree on alarming share hate and misinformation content in these media. The proliferation of hateful content on social media facilitates interactions between various actors, including leaders of armed groups, public officials, and diaspora communities, emerging cross-border identity networks where hateful narratives and conspiracy theories are created, enhanced, and disseminated (Ndahinda & Mugabe, 2022). If we compare disinformation and hateful content and the scope of coverage according to combinations of expressions, then in connection with/without the concept of "globalization" the frequency for "anonymity" is 14538/0, for "hate" 10190/114555, for the combination of "hate and anonymity" 3000 /0, "hate and hoax and populism" 106/0, "hate and populism" 1278/0, for "hoax" 0/14074, "populism" 4855/26055 and for "no information" there are 565137/1202069 occurrences. Research confirms the relevance and extent of the social problem and confirms the need to implement proactive measures (Ramírez-García et al., 2022). The identification of user behaviour in relation to the distribution of information confirms the conclusions mentioned by Olaniran (2022), especially the fact that social networks have evolved into a platform for fake news and propaganda, which reinforce negative and anti-social sentiments. Alarming is the recommendation that appears in several studies that it is necessary to find a way to maintain reasonable dialogues that support democratic principles. As an example of the influence and importance of disinformation, some authors cite the fact that the alternative right group was able to manipulate the election of President Trump, Brexit, or was able to shift public rhetoric (Olaniran, 2022). Currently, these tendencies can be observed in the Russia-Ukraine conflict, or in the opinion pressure on the democratic perception of the Hungarian Prime Minister Orbán. The influence of social networks in the area of the Green Deal and the energy crisis is also indisputable. An analysis of information distribution proved Olaniran's (2022) claim about the degree of manipulability. Analysis of the following group of keywords "populism analysis hoax hate globalization", "populism Facebook analysis hoax

hate globalization", "populism social networks analysis hoax hate globalization" and "populism social media analysis hoax hate globalization" identified 30, 19, 27 and 30 respectively occurrences in the database. If we narrow the selection to scientific publications, then the frequencies are 6,5,4,6. In scientific publications, there was no publication in any group of keywords in the last year, during the previous year 12,9,12,12 publications were published in the entire database, in the scientific literature 1 publication was recorded for all these combinations (Pérez-Curiel & García-Gordillo, 2021), which demonstrates misinformation and hateful reactions in a global environment. This is how our research demonstrates the suitability of targeted keyword mining in publication databases. A significant feature of the current trend of disinformation and the targeted dissemination of a specific type of information (Hoaxes) to targeted groups is the combination with automation, such as robots, where social media becomes a tool for digital forms of propaganda. These forms can be compared to the very known fact of Goebbels propaganda, where disinformation targeted at individuals led to a change of thinking across society, provocateurs played the same role in this propaganda, comparable to today's trolling. A typical sign of social media manipulation is also the targeted distribution of fake news and propaganda (for example, fake stories spread from fake, fictitious or stolen user accounts), which is able to generate more engagement than content from real news sources. The subsequent sharing of false stories has a synergistic effect, where there is not only an avalanche spread, but also the effect that users are not interested in any news that disagreed with or deviated from their accepted assumptions and conclusions (PBS Newshour, 2016). Subsequently, people continue to actively seek out and present unknowingly false information if it supports their opinion spectrum. In this sense, the global marketing of information hoaxes is characterized in particular by the effort to convince with its importance, or by the effort to present shocking information, new dangers. They are also characterized by an effort to convince that the information (warnings about certain forms of danger, typically for example about the harmfulness of the Covid vaccination, about refugees, about the Bolsheviks, about the USA, etc.) is distributed by trustworthy sources, or that the warning comes from trustworthy sources ("WHO warns...", "the government warns..." etc.). Very often in global information marketing it is possible to identify information that is disseminated as an alternative to official information. In this case, it is usually suggested to the recipient that this unofficial version is censored in some form by default, and the recipient is offered "original", uncensored information. This information is characterized by an avalanche-like spread in specific groups. Very often, the information is emotionally tinged ("attacks feelings"). The nature of a hoax is supported by the content of lies and half-truths that an uninitiated person cannot assess with certainty, contains inaccurate, distorting information, purposefully edited half-truths or a mixture of half-truths and lies. Some authors (Shin, 2022) even use the term "social contagion". Also Rasel et al. (2018) states already in 2018 that the spread of aggressive tweets, statuses and comments on the social network is gradually increasing. People use social media as a virtual platform to troll, blame, blaspheme and slander each other. These activities spread hatred between race, religion, etc. Therefore, these comments should be identified and blocked on social media. In this context, we can therefore talk about marketing and management in digital platforms. If we gradually compare the frequencies in relation to the term marketing, we observed occurrences in the combinations "globalization", "globalization Facebook", "globalization social networks" and "globalization social media". The number of occurrences was relatively high for management: 62647 (52035), 4570 (2703), 3386 (26430) and 35824 (28295), the value in parentheses indicates the number of identified references in scientific publications. For marketing, the number of occurrences was 23957 (18746), 2813 (1548), 15000 (10814), 16309 (12017).

Comparing with the previously mentioned data, it can be seen that the combination "marketing-globalization" has a similar number of occurrences as "Facebook" (62647/65555). The identification of relationships and connections is quite complex in social networks, in order to detect suspicious links within user communities, there is a set of classification systems based on the identification of fake profiles, the degree of agreement with the content of shared information, or on the coefficient of mutual clustering and profile information of users (Wani & Jabin, 2022). Profile information helps find similarities between users. A considerable number of studies point to the necessity of identifying hate speech and intensive intervention against such speech. The method of automatic detection of hate speech in posts on social networks is often challenged by the complexity of capturing the context of user expression with potential hateful intent. Senarath & Purohit (2020) note that semantic features can help enrich the contextual representation of word meanings in a social media post for machine learning algorithms. And make a significant contribution to the suppression of hateful and disinformation processes on social networks. We can recommend these trends for the most frequent occurrences of our research: "social media" (635662 occurrences), "social networks" (500852), "Facebook" (65555), "globalization" (98433), "analysis globalization" (81766), "management globalization" (62647), "globalization social media" (49281), "analysis globalization social media" (45,018), "globalization social networks" (43400) and "analysis globalization social networks" (40419). There are also studies that question the importance of misinformation in social media. For example, Allen et al. (2021) states that fake news makes up only 0.15% of Americans' daily media diet. The authors directly state: "Fake news, broadly defined as false or misleading information masquerading as legitimate news, is frequently asserted to be pervasive online with serious consequences for democracy. Using a unique multimode dataset that comprises a nationally representative sample of mobile, desktop, and television consumption, we refute this conventional wisdom".

However, our research and the frequency of published studies on this issue indicate otherwise. There are also studies that rely on the personal responsibility of network users and assume that a combination of implemented security rules in the network and an active civic approach of users (reporting of misinformation and hoaxes, a sense of personal responsibility) will enable the elimination of hate and misinformation in the networks in the future (Gagrcin, 2022). , however, this method is problematic because, as was said in the introduction, the standard truth is not unambiguously declared and can be interpreted differently by different groups. Some authors call for the creation of a formula for moderating content on which platforms and public institutions collaborate, from the field of corporate social responsibility or public diplomacy (Doncel-Martin et al., 2022). the authors analyse, in the case of the European Union, its "Code of conduct to counteract illegal online hate speech", which included the involvement of different social media companies. It is debatable whether the introduction of self-censorship, censorship, or even legislation to determine what is safe content is a democratic practice, as it is nothing more than the introduction of global rules to dictate what is right and what is not. Our analysis did not confirm a trend in the context of the dynamics of publishing the terms "management" and "marketing", which would indicate content moderation from a position of social responsibility. By comparing the slope of the lines for individual occurrences in the given time interval, combinations of terms containing "marketing" and "management" have slopes below the average value (average of 0.152 for the entire database and 0.171 for scientific publications). The combination of "management globalization social media" (0.143 and 0.148), "marketing globalization social media" (0.137 and 0.146) had the highest value. In general, as was said in the introduction, it is very difficult to distinguish between information and disinformation, it is not an exception that information about

disinformation is labelled as disinformation, as happened, for example, in a discussion on the Twitter network with the source O'Brien & Alsmadi (2021).

Conclusion

Some authors (Wani & Jabin, 2022) propose a classification system mapping four basic and easily accessible functions, work(w); education(s); home city (ht) and current city (cc). However, it turns out that mapping is not enough with classic methods of analysis, with cluster analysis, rather it is necessary to apply methods of machine reading, artificial intelligence and knowledge analysis. Our research showed that the scientific publications recorded the greatest dynamics in combinations of keywords, especially "populism social networks analysis hoax hate globalization" (slope of the line 0.250), "populism Facebook analysis" (0.229), "hoax Facebook" (0.223), "populism Facebook" (0.221), "hoax Facebook analysis" (0.220), "populism Facebook analysis globalization" (0.217), "populism social media analysis hate globalization" (0.212), "populism Facebook analysis hate globalization" (0.208) and "populism social networks analysis hate globalization" (0.206). Similarly, if we were to observe how many years we would need under the current dynamics to achieve the same number of published outputs as the current number of all published scientific outputs for the relevant group of keywords, then within five years it would be groups of "hoax" and " populism" in combination with "Facebook" and "social networks", respectively with the keyword "analysis". This fact is alarming, because it points to a significant dynamism and acceleration of the very means of expression that are used for misinformation, attacks, insults and intolerance. It is obvious that an ethical process will have to take place in the environment of digital platforms, but the question is whether the environment of these platforms does not only reflect the image of the current times. The negative bias of the media was also confirmed, giving prominence to a rhetoric of disinformation that overlaps with the theory of populism.

Abstract

Research background: The previous two summers, i.e., the summers of 2020 and 2021, were not very favourable for tourism. According to the media and researchers, the global Covid-19 pandemic has hit tourism the hardest of all industries. After the forced closure of tourist businesses and countries, the war in Ukraine has hit the global economy, bringing many problems to the global world. Currently, the gastronomy sector, as one of the components of the tourism industry, faces not only a lack of qualified labour but also an energy crisis and rising inflation, which fundamentally affect the competitiveness of businesses and the demand for gastronomic services. After the initial positive development after the pandemic, due to inflation, the hospitality services market is once again in trouble, and this development can be liquidated for many businesses.
Purpose of the article: The purpose of this article is to analyse the development of factors that influence the activity of gastronomic services in the Czech Republic, primarily in the context of the development of the price level and then the connection between the development of inflation and the number of visitors to restaurant establishments.
Methods: The research results will be based on the comparison of hard data, which will be processed using mathematical-statistical data. The basis for the analysis and comparison was quarterly data for the period 2019–2022 from the Eurostat database, the Czech Statistical Office, etc. Furthermore, the conclusions will be supported by primary research clarifying attitudes towards restaurant attendance at a time of increasing inflation.
Findings & Value added: Although there is an increase in sales in gastronomy, it is clear that this increase is caused by an increase in prices. Increasing consumer prices in the hospitality industry and the financial burden of meeting basic needs lead to a decrease in demand for restaurant services. The decrease in attendance is also the result of the formation of new habits that were already formed during the global Covid pandemic.

Keywords: *gastronomy; inflation; Czech Republic; demand*

1 Introduction

After a relatively long period of paralyzing tourism, all restrictions were terminated at the end of 2021 (beginning of the pandemic 11.3.2020 - 5.5.2021 end of the pandemic state of emergency), and tourism (hotel services, gastronomy) could fully resume. The initial increase in restaurant footfall after the end of covid restrictions was partly dampened by the adoption of new behaviour patterns by the clientele. As a result of covid measures, many customers stopped visiting restaurants and started spending more time at home with friends, many of them started preparing food at home, thinking it was better and cheaper or stuck with boxed food. The optimistic outlook for the new start of the economy and tourism was again interrupted by new circumstances; the covid period was replaced by the war in Ukraine and the energy crisis and a dynamically increasing inflation rate. The results of the study by Khana et al. (2022), show that terrorism, which hinders peace and security, the amount of expenditure and rising inflation have a strong impact on the tourism sector. Tourism is very sensitive to economic fluctuations and trends in the world economy. According to the WEF (hereafter World Economic Forum 2019), the top nine global economic risks include: "*asset bubbles; deflation; the failure of a significant financial mechanism or institution; failure/lack of critical infrastructure; fiscal crisis in key economies; high structural unemployment or underemployment; illegal trade; strong energy shock; unmanageable inflation*" (Asgary and Ozdemir (2019). At present, the European market is struggling with rising inflation and energy price shocks (propellants, gas, and electricity). Inflation is an increase in consumer prices, according to Erosa and Ventura (2002) it is a regressive consumption tax. The increase in prices in tourism is caused on the one hand by the demand for tourism; on the other hand, supply inflation pushes tourism prices up. Supply inflation is caused by rising input prices (energy, fuel, etc.), seasonality or inelasticity of supply.

2 Research literature

The issue of the impact of inflation on restaurant facilities was addressed by Uddin and colleagues (2020), the authors' group indicated that the American restaurant sector responds to shocks from food price fluctuations, food price fluctuations will undermine the performance of the restaurant sector and have homogeneous effects on its performance. They state that overall inflation may pose less of a risk to the restaurant sector from a customer perspective than fluctuations in food prices. According to Nakamura (2022), an increase in inflation leads to a loss of welfare, studies show that inflation affects people on the poverty line and the middle class the most, which will lead to the possible collapse of many restaurants In the event that inflation continues to rise, it may mean a constant increase in prices, which will lead to the denial of goods that are not absolutely necessary (accommodation, vacations, and other expendable goods). A similar development of the decline in tourism was manifested in connection with the financial crisis of 2007, when there were fears of a recession, the rise in fuel prices, and rising inflation led to a reduction. Research confirms that the effects of inflation on catering services are part of the effects of inflation on services in general. When analysing dining in restaurants, 55.41% of people said that the price of food is the main factor before the quality of restaurant service. This shows that inflation has led people to emphasize the price of food over the type of cuisine, novelty, and specific menu item. In general, 53.50% of the respondents felt the need to switch to lower-quality foods due to high prices. This shows that inflation has caused people to place a high priority on the price of food over its quality. The authors compare their results with the Nielsen Inflation Survey, which assesses the impact of inflation on the middle class around the world. In this survey, 85% of the respondents said that rising costs

have affected their choice of food products, and many said that it affects spending on activities such as dining, snacks and entertainment. Based on a questionnaire survey, Asgary and Ozdemir (2019) stated that respondents consider the economic threats of tourism with serious impacts of uncontrolled inflation, strong energy shocks and fiscal problems in key economies; from a geopolitical point of view, it is a global conflict with regional consequences and a failure of governance, which are the focus of economic threats. Research on factors affecting the sustainability in BRI countries identified a positive relationship between sustainability and tourism, per capita income (closer to Iftikhar et al., 2022), and a negative relationship between sustainability and inflation in both short and long term. It is obvious that the consumption of the population is one of the important factors of sustainability; the level of income and the price level determine consumption. It is not possible to look at inflation only from the perspective of customer priorities (price of food, price of services, purchasing power per capita). It is necessary to see that an important factor for the use of the service (eating in a restaurant facility) is the necessary existence of this service, i.e., the sustainability of the service itself, i.e., the sustainability of the restaurant operation. From this perspective, Kim et al. (2019) investigated mergers and acquisitions of restaurants and accommodation establishments, based on 16 macroeconomic factors, the authors showed that inflation (along with the factors "total activity", "market value", "cost of debt", etc.) significantly affected the frequency of deals in the segment hospitality. From the customer's point of view, they confirm the fact that restaurant establishments can undergo restructuring in times of inflation and maintain an acceptable price level of services for the customer in the event that inflation is at an acceptable level for both the customer and the operator. It is necessary to see that an important factor for the use of the service (eating in a restaurant facility) is the necessary existence of this service, i.e. the sustainability of the service itself, i.e. the sustainability of the restaurant operation.

3 Data and Method

The aim of the contribution was to analyse the influence of current economic events on the development of gastronomic services. Above all, this is about the development of inflation. The data for the preparation of the article were obtained from a search of the professional literature and the database of the Czech Statistical Office (Public Database CSO), as well as from the database of the Czech National Bank (ARAD, CNB). Research results are based on a descriptive analysis of quarterly year-on-year changes from 2019 to 2022. Due to the availability of data, the time series ends in July 2022. The relationship analysis was then determined based on the Spearman correlation coefficient (1), which allows one to analyse the link of data that do not have Student distribution. Correlation analysis was performed using the SPSS software tool. Acceptance of the relationship is determined on the basis of the p-value, if the p-value is less than the significance level of 0.05, then the correlation coefficient can be considered statistically significant. The correlation coefficient takes on the value of the interval $\langle -1; 1 \rangle$. The value of the correlation coefficient then indicates the strength of the relationship, where values up to $\left|0.7\right|$ indicate a strong relationship, on the contrary, values up to $\left|0.5\right|$ indicate a medium strength of the relationship, and coefficients smaller than $\left|0.5\right|$ represent weak or no linear dependencies. If there is no relationship between the variables, then it is impossible to deny the relationship, using correlation analysis we accept the statement that there is a negative (negative value of the correlation coefficient) or positive (positive correlation coefficient) linear relationship between the variables (closer Janse, 2021). Furthermore, the research conclusions were expanded to include surveys of attitudes toward the attendance of restaurant establishments

depending on the increase in the price level, which were carried out by renowned companies and by our own preliminary research, in which 50 respondents.

$$r_s = 1 - \frac{6\sum_{i=1}^{n} d_{i=1}^{n}}{n(n^2-1)} = \frac{6\sum_{i=1}^{n}(x_i y_i - n\overline{x_i y_i})}{n(n^2-1)} \tag{1}$$

Where: rs – correlation coefficient, n – number of observations, sx/sy standard deviation, x, y = variables

4 Results

As can be seen from the graph of sales in gastronomy and catering, the year-over-year development (SOPR =100) records an increase in sales. The restart of Czech gastronomy was recorded in the second quarter of 2021, specifically in April 2021. This increase was mainly associated with the revival of the economy, and the end of restrictions on restaurant establishments. Hunger for social life and long isolation caused the return of guests to restaurant facilities. The rise in prices in gastronomy was driven by demand (Hradil, 2022). Accordingly, the new trends identified above manifested themselves here. At the end of 2021 and the beginning of 2022, the situation in restaurant establishments began to improve, restaurants recorded an increase in visitors, mainly guests went to standard restaurants and beer food establishments (49%), followed by classic pubs and pubs (41%), and the lowest increase was then cafes and café bars (35%). The situation in the restaurant segment was better than in hotel services.

However, the increase in sales in recent quarters is more associated with price increases on the supply side than with an increase in demand; inflationary pressures cause this from energy and food prices. A similar development was noted by the American research of Rizwan (2021), when it was found that with the growth of inflation there was a reduction in the number of items on receipts (from 3.8 to 3.5); however, sales in gastronomy recorded growth.
Figure 9. Development of the economic situation of households in the Czech Republic (left) and catering and hospitality sales, inflation rate (right)

Source: own processing, data Public Database CSO (2022), CNB ARAD (2022)

Nevertheless, it is necessary to state that the growth of prices in gastronomy is not as fast as, for example, the growth of fuel, and the prices of gastronomic services are growing more slowly than the prices of accommodation services. However, Czech inflation is currently the highest since 1993 (Inflation - 2022, rate of inflation and its development in the Czech Republic - maximum, 2022, 1993 = 18.2%). According to the Hloch report (2022), although the number of customers was increasing, the beginning of 2022 was already associated with a decrease in sales in gastronomy. The increased number of

customers did not lead to increases in sales, many customers began to reduce spending, and the decline in sales between 4Q 2021/1Q2022 was up to 3%. Today, many clients give priority to quality and quantity, there are more customers who order only the main meal and forego soup and dessert (TTG, 2022).

The main cause of the decrease in sales in restaurants is the cautious behaviour of visitors, who are forced to face the current development of inflation, especially the rise in energy and food prices, and the rise in mortgage interest rates, which greatly drain the financial budgets of households. At the expense of other goods, the reason being the gradual increase in the price of gastronomic services. Another serious factor limiting gastronomic services is the development of real wages of residents, even if there is an annual increase in wages, this is an increase in nominal wages, and real wages are decreasing year-on-year (see Figure 1). , 2Q/2022-2021: drop in real wages by approx. 10%). The positive development in gastronomy is not supported by the situation where more and more households in the Czech Republic fall to the poverty line due to the economy. Since 2019, the level of material poverty in the Czech Republic has almost doubled (Košlerová, 2022) and we can state that if the government's decisions are not preserved, poverty in the Czech Republic will continue to deepen.

Based on the correlation analysis (Table 1), it is clear that a decrease in real wages (r_s = 0.485, p=0.08) will result in a decrease in sales in hospitality and hospitality. The correlation coefficient did not confirm a linear relationship. It was also not confirmed between the year-on-year change in sales in catering services and hospitality and the year-on-year growth in nominal wages, the year-on-year change in sales in gastronomy, and the year-on-year growth in sales price increase, Telephone products, Household appliances, Food and beverages (alcoholic and non-alcoholic), and Food and hospitality. Reverse binding (r_s = -0.708 p =0,005) was "education", it is replaced by the fact that in the event of an increase in the possible costs of education, citizens will limit their visits to the restaurant. On the contrary, sales growth is related to inflation growth, linear links were also confirmed within the growth of the items listed in table (1).The year-on-year increase (inflation rate) is most pronounced in transport (2Q/2022, 124%), which also showed the highest correlation value (r_s = 0.86 p = 0.001). It is obvious that if the prices of the products listed below rise due to the influence of gastronomy as a multidisciplinary industry, the costs of companies will also increase, which will be reflected in the prices of gastronomic services.

Table 1. Results of the correlation analysis of the relationship between sales and year-on-year inflation of selected consumer prices

	Inflation rate	Housing, energy, water, gas	Health
Coefficient	0,646*	0,675**	0,576*
p-value	0,013	0,008	0,031
	Transport	Education	Other
Coefficient	0,701**	-0,708**	0,602*
p-value	0,005	0,005	0,023

4.1 Customer attitudes towards the visitation of gastronomic establishments at a time of increasing inflation

The problem with price increases is no longer only low-income groups, and single mothers, but even now the lower middle class also suffers from financial problems (CT24, 2022). The fact that the situation for Czech gastronomic businesses will not improve in any way is confirmed by a questionnaire survey by Generali Investment (CT24, 2022), and Portal Seznam.cz also came up with similar results (1,034 respondents, Czechs and inflation,

2022). Both studies indicate that with an increase in the price of common necessities, the inhabitants of the Czech Republic will reduce their expenses, primarily by limiting visits to gastronomic establishments (see Table 2). Likewise, the Prima STEM survey for CNN NEWS states that high prices discourage up to 7 out of 10 potential visitors from visiting a restaurant (Idnes, 2022).

Table 2. The impact of inflation on the consumption of services by households

Generali Investment *	List of News (How they see their situation at the time of rising inflation) *	STEM*:
<u>Visits to restaurants</u> **Buying clothes** **Smoking and alcohol** **Holiday** **Grocery shopping** **Culture** **Presents** **Sport**	<u>Visits to restaurants or cultural events (52%)</u> Buying clothes (46%) Grocery shopping (41%) Heating (37%) Transportation expenses (26%) They will not feel the effects of inflation (24%) Call expenses, internet (12%) Will have problems repaying the mortgage, loans (5%) Will need to borrow funds (2%)	Shopping for groceries (69%) <u>Restaurant visits (68%)</u> Energy consumption (66%) Buying clothes (65%) Sports and culture (65%)

Source: own processing, CT24 (2022), Češi a inflace, (2022), CNN Prima News, (2022). * Research question: Which areas will the citizens of the Czech Republic restrict?

Our own research shows similar results, where up to 80% of people have reduced their visits (50% definitely agree, 29% "agree" with the statement that they have reduced their visits to restaurants), and only 9% did not have to reduce the frequency of visits anyway, and 11% took a neutral position on the matter. Of the 80% of the respondents who reduced restaurant visits, only 7.1% of the respondents remained within the original range of drink consumption, and 57% were inclined to limit food consumption. Of those who have already reduced attendance continuously, they have reduced restaurant attendance due to business closure during the pandemic (8.9% of respondents).

5 Discussion and Conclusion

Restrictions on restaurant operations are clearly related to a decrease in spending on consumer goods during the period of rising prices (Ryngaert, 2022). A decrease in the number of clients, a decrease in sales, and an increase in operating costs will clearly lead to a decline of hospitality and hospitality operations. The issue of effective business operations is addressed by a number of authors, e.g. in 2012, Munjal and Sharma (2012) published a study where they draw attention to the need to look for mechanisms that will maintain revenue growth in the restaurant services sector. At the same time, the authors point out that this need is more pronounced in the segment of cheap restaurants. The authors recommend innovations and innovative practices for the acquisition of beverages, food, and related raw materials as a tool for the survival of the analysed market segment. The authors directly state: "*The research helps owners and operators draw on innovative practices and approaches used to achieve better fiscal performance when it comes to managing food costs without adversely impacting the customer experience and overall business profitability*".

For the sustainability of customers, it is therefore necessary to look for new strategies and pricing practices that the customer will be willing to accept. For example, Webb et al. (2022) directly suggest that in order to retain the customer it is necessary to differentiate the price offer and the service offer, the authors propose the application of the Priority Mixed Bundle (PMB) strategy, which solves the possibility of customer segmentation, price

differentiation and price discrimination (restriction of part services to less solvent customers). Customers can make reservations if they are willing to commit to dining on the prix fixe menu, while patrons can dine A la Carte. In this way, in the event of a decrease in the customer's solvency due to inflation, acceptable services can still be provided.

In a number of studies, it can be traced that not only the quality of services but also the so-called price fairness can be an important factor in maintaining attendance. Along with food quality, service quality (employee service quality), and physical environment quality, these are important factors for customer retention (Singh, 2022). The emphasis on the fairness of prices and the quality of services aimed at increasing customer satisfaction is also stated by Ahmed et al. (2022), who also mention the term "customer loyalty" in this context, this factor can play a significant role in the customer's willingness to use restaurant services even in times of inflation.

Abstract

Research background: This growing wave of digital transformation gains more and more strength, especially with regard to accounting practice and research. The prestigious literature rarely provides evidence of the impact of digital transformation on accounting practice and research in an emerging economy.

Purpose of the article: In this article, we tested a research framework capable of capturing the relationships between digital transformation and the resilience of accounting practices and research in an emerging economy, such as Brazil, during the COVID 19 pandemic.

Methods: Primary survey-based data were collected from multinational companies and federal public universities. The survey was applied to 41 experts with experience in accounting and 41 researchers from Brazilian federal public universities. Data were treated using data mining techniques. Spearman's correlation analysis was used to show the effects of digital transformation (dynamic capabilities) for resilience research and practice in accounting. The R software was used to perform the tests.

Findings & Value added: The results of our research are as follows: (i) the resilience of accounting research and practice has been affected by digital transformation in the COVID 19 pandemic period; (ii) planning and problem solving skills were the most relevant for accounting practice in multinational companies; (iii) planning and learning capabilities were the most relevant for accounting research. Finally, the results can serve as a guide to improve the performance of accounting practices and research from digital transformation.

Keywords: *digital transformation; accounting practice and research; resilience*

JEL Classification: *A11; A14; B16*

1 Introduction

The COVID-19 pandemic took the world by surprise in early 2020, and the economy continues to experience a substantial slowdown, with implications for organizations. These abrupt changes (such as the one caused by COVID 19) helped to accelerate the processes of digital transformation of organizations and their network (Queiroz and Fosso Wamba, 2021) by seeking to develop resources and capabilities to enable and improve the resilience of organizations. In light of the unprecedented global crisis caused by the COVID-19 pandemic, resilient organizations are the most likely to transition into the post-COVID era (Hadjielias et.al., 2022). Business research and practices have been highlighted in the mainstream literature as highly desirable because it addresses the urgency of investigating vulnerability situations. In this context, accounting, as a mechanism providing information to different stakeholders, was one of the activities that most suffered the impacts of new technologies since the fourth industrial revolution (Geerts et. al., 2013). These new technologies favour greater accuracy and interpretation of financial (Alhtaybat and von Alberti-Alhtaybat, 2018), social and environmental information to support the decision-making process in organizations. In this sense, the growing wave of digital transformation is increasingly gaining strength, especially with regard to accounting practice and research.

Digital technologies (blockchain, IoT, Big Data, AI, etc.) are relevant enablers in this process because they can substantially influence business performance. In addition, the literature indicates the positive effects of digital transformation to add value to businesses (Oliveira and Trento, 2021). Gong and Ribiere (2021) included dynamic capabilities as a determining mechanism in defining digital transformation. Thus, he argues that the results of accounting practices and research can be improved through dynamic capabilities. And this is relevant because it can enhance the quality of information provided by accounting to support the decision-making process (customers, shareholders, suppliers, government and other stakeholders). Specifically, this study relates the dynamic capabilities and performance of accounting practices in multinational companies and accounting research performance in Brazilian public universities. These double collaborative results can enhance the role of accounting, guiding organizations in their best performance: economic, social and environmental.

Thus, there is an urgency to identify the most relevant dynamic capabilities to make accounting practice and research more resilient in their purposes, such as creating value for customers and other stakeholders (shareholders, suppliers, investors, communities, governments, etc.). Therefore, this research aims to highlight the main impacts of digital transformation for the resilience of accounting practices of multinational companies from different sectors and for accounting research in Brazilian public universities. There are few studies that address the effects of digital transformations in the field of accounting (Al-Htaybat et. al., 2018; Geerts et.al., 2013; Burritt and Christ, 2019). This study is original and presents contributions: a) it improves the understanding of priorities of dynamic capabilities to achieve the resilience of accounting practices and, with that, improve the quality of information for decision makers; b) improves understanding of dynamic capabilities priorities for better accounting research performance; c) improves the understanding of the priorities of dynamic capabilities necessary for managers to focus their efforts on enhancing the role of accounting as a facilitating mechanism for decision-making in organizations; d) improves the importance of understanding the aligned and collaborative role between universities (research) and Brazilian multinational companies (accounting practice) to achieve more resilient performance; e) allows advancing the body of knowledge in the field of accounting practice and research. This article is structured according to the following sections: Digital transformation, dynamic capabilities and resilience ; methodology, results and analysis; and conclusions.

2 Digital transformation, dynamic capabilities and resilience

The prestigious literature highlights some definitions of digital transformation (Ashmarina et al., 2020). However, its meaning lacks an exact description (Haffke, Kalgovas and Benlian, 2016, 2017.) However, this transformation is usually defined by researchers as the organization revolution driven by the development of digital technology changing the way business is conducted. Reddy and Reinartz (2017) suggest that digital transformation (DT) can be conceptualized under two strands of literature, the first refers to the traditional sense that relates digital transformation to the technological advancement of computers and the internet to carry out a job efficient and effective, the second approaches the broader knowledge of the transformation from the point of view of organizational performance in order to analyse the impacts of its application through the way in which they started to carry out their activities, observing the generation of their wealth by through this process. As a complement, this process is denoted as the integration of digital technology and enterprise resources in a digital economy (Liu et. al., 2011) outlining a new way of carrying out activities that provide sources of value (Bumann and Peter, 2019) .

Gong and Ribiere (2021) unified the concept of digital transformation including technologies; human, knowledge and financial resources; digital and dynamic capabilities. From this definition, this study adopts dynamic capabilities as the definition of digital transformation. According to Teece, Pisano and Shuen (1997), dynamic capabilities is the ability to integrate, configure and build a series of resources and external competences to deal with sudden changes in the environment, being classified as an "intensely entrepreneurial" dimension because in addition to adapt, companies shape themselves through innovations to business ecosystems, being subdivided into 03 processes (Teece, 2007): ability to detect and shape threats and opportunities (Sensing), ability to enjoy (take advantage of) the opportunities found (Seizing) and the Ability to Maintain Competitiveness through Transforming the Resource Base (Transforming). For Gong and Ribiere (2021), dynamic capabilities can be considered strategic assets to initiate or accelerate the digital transformation journey, when they can be leveraged, reused, combined and safely shared with stakeholders. This study adopted the definition of digital transformation proposed by Gong and Ribiere (2021), who consider technologies; human, knowledge and financial resources; and dynamic and digital capabilities as an integral part of this definition. This study adopts dynamic capabilities as a definition for digital transformation. That is, this study partially adopts the definition of Gong and Rubiere (2021).

The dynamic capabilities adopted in this research are as follows (Teece, 2018; Day and Schoemaker, 2016; Teece, Pisano and Shuen, 1997): adaptation, problem solving, entrepreneurship, innovation, planning, critical thinking, leadership, uncertainty management, strategy, conflict management, learning and digital. In this way, we believe that digital transformation, represented by dynamic capabilities. can positively affect the resilience of research and accounting practice. Resilience can be defined as the ability of socioecological systems to absorb disturbances and reorganize in the face of change (Kennedy, Martina, and Linnernluecke, 2022). Academic resilience research has the potential to improve the learning outcomes of students at risk of school failure, but there is no standard approach to measuring it (Rudd et.al., 2021). The pressures brought on by the global COVID-19 pandemic in 2020 have amplified the importance of academic resilience and highlight the importance of a shared view of academic experiences (Cohrssen et.al., 2022). Responses to academic papers in this context have received little research attention, despite their universality during the pandemic. Failing to recognize or "invisible" the roles and needs of academics during a pandemic is a significant concern (Cohrssen et.al., 2022).

Firm-level resilience is associated with the ability of organizations to respond and recover faster (Kennedy, Martina, and Linnernluecke, 2022).

Thus, companies are increasingly trying to increase their ability to improve organizational resilience in companies and respond to crises, as was the case with the COVID 19 pandemic (Aksay and Şendoğdu, 2022). The concept of resilience suggests the ability to emerge stronger from difficulties (Bryce et al., 2020). In summary, the term organizational resilience has been used to explain the organization's ability to respond and recover quickly against unexpected environmental turmoil and events such as economic crises, epidemics and disasters (Denyer, 2017; Aksay and Şendoğdu, 2022). In this study, the term resilience is represented by global performance (Khalil and Belitski, 2020; Makkonen et.al., 2014) for research in federal public universities and accounting practice in companies. The dominant literature (Akpan, Johnny, and Sylva, 2021) highlights that dynamic capabilities are positively correlated with measures of organizational resilience. Thus, we believe that dynamic capabilities increase resilience in companies and in accounting research. Thus, we present the following hypothesis:

H: Dynamic capabilities positively impact the performance of accounting research and practice.

3 Methodology

A systematic literature review was carried out to identify the definition of digital transformation. As highlighted in the literature review, this study adopts the proposed definition by Gong and Ribiere (2021), in which the authors dedicated their investigation to finding a definition for digital transformation. 134 definitions for digital transformation were raised and from these results, the authors presented the following unified definition for digital transformation: A fundamental change process, made possible by the innovative use of digital technologies accompanied by the strategic leverage of key resources and capabilities, with the objective of radically improving an entity and redefining its value proposition for its stakeholders (An entity can be: an organization, a business network, an industry or society). From this definition, the approach of this research was based exclusively on dynamic capabilities. The next step was to select the main dynamic capabilities from the main literatures (Teece, 2018; Warner and Wager, 2019, Helfat and Winter, 2011). Finally, in the literature (Khalil and Belitski, 2020; Makkonen et.al., 2014; Day and Schoemaker, 2016, Schilke, 2014) the different metrics for evaluating capabilities performance were identified. This study was dedicated to global performance for both research and accounting business practice purposes.

Once the research was carried out based on the referenced literature, the next step was to prepare the questionnaire to carry out a field research aimed at evaluating the effects of the independent variables (dynamic capabilities) in relation to the dependent variables (global performance) through of consultation to respondents. Thus, the questionnaire was prepared based on the literature, in which capacities and performance were integral parts of the aforementioned data collection instrument. The questionnaire was structured in two parts: general information and technical information regarding the effects of abilities on performance. It is worth mentioning that we sought to maintain the objectivity and simplicity of the research instrument, which had, in its characteristics, being semi-open and having mostly objective questions. In summary, the data collection instruments were systematized in two sections: The first section in both questionnaires was intended for the collection of contact data of the professionals of the companies and researchers and general information, and the second section was responsible for the evaluation of the effects of Digital Capabilities for Research and Practice in Accounting, containing 12 questions asked using the Likert scale, as mentioned above, in addition to a discursive question regarding

the impacts of digital transformation on the work/research environment. Regarding general information for professionals in the accounting practice, the following were requested: sector of activity, position in the company in which they work, time of experience in the company, size of the company in which they work, company name, state and municipality where the entity is located. For the questionnaire carried out with PhD professors, an optional discursive question was added so that these professionals could discuss their process of adapting to technological advances in the midst of the Covid-19 pandemic.

Regarding general information for researchers, the following information was requested: Maximum degree, area of training, time of work at the university as a researcher, last research developed and state and municipality in which it operates. Before sending it to the professionals, three (03) pre-tests were carried out in order to eliminate inconsistencies identified by the respondents. Soon after this procedure, two invitation letters were prepared and sent to the researchers of the HEIs (Universities) and also to the professionals who work in the accounting activities of the Companies. Mappings were carried out to facilitate the identification of professionals who work in accounting practice and also of professors involved with research at HEIs. Thus, two field surveys were applied using the scalar-type questionnaire (Likert), with degrees from one (1) to five (5), with one (1) as the lowest degree of impact and five (5) the highest degree. of impact. Thus, at first, data collection was carried out from the professionals of the companies using the professional network LinkedIn, in which the professionals were selected by technical-scientific criteria, with vast experience and extensive knowledge about this research object. In this way, questionnaires were submitted to 280 experts during the months of November (2021), December (2021) and January (2022). Of this total, 41 questionnaires were answered. In order to obtain a greater number of consistent responses, the questionnaires were sent back three times to the experts who did not provide any feedback. Therefore, professionals in the accounting area such as: Accountants, Auditors, Controllers, Accounting Data Analysts and Accounting Managers, etc., who work in the state of Rio de Janeiro, São Paulo and Rio Grande do Sul in small, medium and large, with a view to evaluating the effects of dynamic capabilities in relation to business performance.

Data collection from HEI researchers was carried out with the objective of verifying the influence of dynamic capabilities in relation to research performance, it was developed through various contacts with federal universities. We emphasize that these professionals were also selected through technical-scientific criteria, with vast experience and extensive knowledge about this research object. Questionnaires were submitted to 453 researchers during the months of November (2021), December (2021) and January (2022). A total of 49 answered instruments were returned, that is, returns were obtained from researchers from 10 federal public universities, most of them PhD professors who have been working in the research area for more than 6 years, trained in Applied Social Sciences. Questionnaires were resubmitted three times to experts who did not provide any feedback. Soon after this procedure, data from the characteristics of the sample obtained using descriptive statistics and Spearman's correlation analysis were analysed.

4 Results and Analysis

In this section, the results obtained through the application of field research and the underlying analysis of the study will be presented, aiming to evaluate the impact of digital transformation from the perspective of independent and dependent variables, as described in the methodological procedures section. Thus, at first, the opinions collected from accounting professionals and researchers from higher education institutions will be exposed and then the results will be presented and analysed. These procedures are detailed below.

4.1 Analysis of the effects of digital capabilities for accounting practice

4.1.1 Presentation of general information of accounting professionals

Through the information collected by the professionals through the elaborated questionnaire, it was possible to obtain consistent and detailed results. The provision of this information was important to support and support the results of the present research, considering that these parameters demonstrate the professional competence of the participants, being able to determine a level of coherence and consistency of the answers provided. The data on the characteristics of the sample obtained are detailed below (Table 1).

Table 1. Presentation of General Information for Accounting Professionals.

Accounting Professionals (n = 41)	Frequency	(%)
Company size		
Small	24	58,54
Medium	10	24,39
Great	7	17,07
Business Sector		
Financial	20	48,78
Accounting	8	19,51
Audit	6	14,63
Board of Directors	4	9,76
Automation	3	7,32
Position in the company		
Counter	26	63,41
CEO	8	19,51
Controller	5	12,2
Accounting Data Analyst	1	2,44
Tax manager	1	2,44
Time of Operation in the Company		
More than 10 years	9	21,95
5 to 10 years	7	17,07
1 to 5 years	15	36,59
Up to 1 year	10	24,39
Brazilian State	37	90,24
Rio de Janeiro	3	7,32
Sao Paulo	1	2,44

When performing a detailed analysis of the information received by accounting professionals through the online questionnaire, it was noted that:

- Regarding business size, it was found that most accounting professionals are part of small companies, corresponding to 58.54%, with 24.39% belonging to medium-sized companies and 17.07% belonging to companies for the most part, this being the smallest group of respondents to this questionnaire.
- Regarding the sector of activity, it was observed that 48.78% of respondents belong to the financial sector, 19.51% are from the accounting sector, 14.63% refer to the audit sector, 9.76% are from the management sector and 7.32% are part of the automation sector. Thus, most of these professionals are from the financial sector and the minority from the automation sector.
- Regarding the occupation, it is possible to affirm that the respondents are accountants (63.41%), CEO (19.51%), auditors (12.20%), accounting data analysts (2.44%) and tax managers (2.44%). Thus, we can conclude that the majority are accountants and the minority are accounting data analysts and tax managers.

- From the point of view of time working in the company, it was found that 36.59% are from 1 to 5 years in the company they currently work, however 24.39% are less than 1 year, 21.95% are more than 10 years and 17.07% are between 5 and 10 years.
- Referring to the state in which they live, it was observed that the largest number of respondents are from Rio de Janeiro (90.24%), but we obtained responses from people who live in São Paulo (7.32%) and Rio Grande do Sul (2.44%).

Thus, based on the responses of the 41 respondents and the parameters indicated in Table 1, the vast majority of accounting professionals who responded to the questionnaire work in small companies, work in the financial sector, are accountants, practice their duties from 1 to 5 years old and are from Rio de Janeiro. The parameters analysed showed that these professionals are highly qualified to provide coherent and consistent information, providing a basis and support for the results obtained in this research.

4.2 Analysis of the effects of digital capabilities for accounting research

4.2.1 Presentation of the researchers' general information

The objective of this topic was to identify, through the developed form, general information about the respondents. In this way, educators from Federal Public Universities were asked to provide some specific data for a robust and relevant analysis, since it is necessary that the respondents have knowledge about the subject addressed in order to demonstrate that the results achieved are reliable. Thus, Table 2 highlights general information about the researchers.

Table 2. General Information of Researchers.

Researchers (n = 49)	Frequency	(%)
Degree		
Doctorate degree	32	65,31
Master's degree	11	22,45
Post doctoral	6	12,24
Training		
Applied Social Sciences	47	95,92
engineering	1	2,04
Human Sciences	1	2,04
Time of experience as a Researcher		
more than 10 years	29	59,18
6 to 10 years	15	30,61
1 to 5 years	4	8,16
up to 1 year	1	2,04
Brazilian State		
Rio de Janeiro	16	32,65
Federal District	6	12,24
Holy Spirit	6	12,24
Minas Gerais	5	10,20
Paraná	3	6,12
Paraíba	3	6,12
Sao Paulo	3	6,12
Bahia	3	6,12
Rio Grande do Sul	2	4,08
Santa Catarina	2	4,08

When examining the responses received by the researchers, using an online questionnaire, it was noted that:

- Based on the degree of accounting researchers, it was found that most have a doctorate degree as the highest degree, which corresponds to 65.31%, with 22.45% composed of researchers who have a master's degree and 12.24% belonging to the respondents, who hold a postdoctoral degree, which is the smallest group in this questionnaire.
- Regarding training, it was observed that 95.92% of respondents are trained in applied social sciences, 2.04% belong to researchers who graduated in the area of engineering and 2.04% refer to those trained in the area of human sciences. Thus, most of these professionals graduated in applied social sciences and the minority in the human sciences.
- From the point of view of time of experience as a researcher, it was found that 59.18% have been working as researchers for more than 10 years, however 30.61% are from 6 to 10 years, 8.16% are from 1 to 5 years and 2.04% are less than 1 year conducting research.
- Referring to the state in which they live, it was observed that the largest number of respondents is from Rio de Janeiro (32.65%), but we obtained responses from people who live in the Federal District (12.24%), in Espírito Santo. Santo (12.24%), in Minas Gerais (10.20%), in Paraná (6.12%), in Paraíba (6.12%), in São Paulo (6.12%), in Bahia (6 .12%), in Rio Grande do Sul (4.08%) and in Santa Catarina (4.08%).

Based on the responses of the 49 respondents and the parameters highlighted in Table 2, the vast majority of accounting professionals who responded to the questionnaire are PhDs, trained in applied social sciences and have worked as researchers for more than 10 years in the institution in which they operate.

4.3 Evaluation of the performance of results

Table 3 shows the robustness test results using descriptive statistics for the impacts of dynamic capabilities on the resilience (performance) of research and accounting practice. A legend is presented for the dynamic capabilities – LEGEND: C1-adaptation, C2 - problems solution, C3 - entrepreneurship, C4 - innovation, C5 - planning, C6 - critical thinking, C7 - leadership, C8 - uncertainty management, C9 - conflict management, C10 - organizational, C11 - learning, and C12 - digital.

Table 3. Descriptive results of dynamic capabilities and resilience in accounting research.

Dynamics capabilities (N = 49)	M	DP	α
Learning	4.0	0.9	0.8
Planning	3.9	1.0	0.8
Critical thinking Entrepreneurship	3.7	0.9	0.8
Problems solution	3.6	0.9	0.7
Innovation	3.5	0.9	0.7
Organizational	3.4	0.9	0.8
Digital	3.2	1.0	0.8
Adaptation	3.2	1.0	0.7
Leadership	3.1	1.1	0.8
Uncertainty management	3.0	1.1	0.8
Conflict management	3.0	0.9	0.8
Entrepreneurship	2.9	1.0	0.9

The results indicated in Table 3 show that capacities have a moderately strong impact on the resilience of accounting research, with emphasis on learning (M=4.0) and planning (M=3.9) capacities. The internal consistency of the questionnaire, measured by Cronbach's alpha, was substantial (M=0.78) as indicated by Landis and Koch (1977). In parallel with the calculations performed for the mean and standard deviation, the Shapiro Wilk test was performed to verify the existence of a normal distribution of the data. In case of statistical

significance, the null hypothesis (H0) is rejected and there is evidence that the tested data are not from a normally distributed population. For this technique, all capacities had their null hypothesis rejected ($p < 0.05$) and do not show a normally distributed population. In this way, it was possible to apply the Spearman correlation test. Table 4 shows the results of correlations (Spearman's coefficient) of dynamic capabilities and research resilience.

Table 4. Correlation coefficient (Spearman) between capabilities and resilience in accounting research

Capabilities	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10	C11
C2	0,7*										
C3	0,5*	0,7*									
C4	0,4*	0,5*	0,6*								
C5	0,5*	0,5*	0,5*	0,8*							
C6	0,6*	0,6*	0,5*	0,6*	0,8*						
C7	0,7*	0,5*	0,4*	0,4*	0,4*	0,6*					
C8	0,3*	0,4*	0,2*	0,4*	0,4*	0,4*	0,4*				
C9	0,4*	0,3*	0,1	0,3*	0,3*	0,3*	0,5*	0,4*			
C10	0,4*	0,1	0,3	0,2	0,2*	0,3*	0,5*	0,3*	0,5*		
C11	0,6*	0,5*	0,4*	0,2*	0,3*	0,5*	0,5*	0,2*	0,4*	0,5*	
C12	0,5*	0,4*	0,4*	0,3*	0,3*	0,4*	0,4*	0,3*	0,5*	0,4*	0,6*

Note: * significant correlation ($p < 0.05$)

Most correlations are positive ($p>0$) and statistically significant ($p<0.05$) (Table 2); that is, when one of the capabilities increases its value, the other capability also increases in the same proportion. The strongest positive and significant correlations are between: C4 - innovation and C5 - planning; C5 - planning and C6 - critical thinking; C1-adaptation and C2 - problems solution; C1-adaptation and C7 - leadership; C2 - problems solution and C3 - Entrepreneurship. Some capabilities are positive, but not significant ($p>0.05$): C2 - problems solution and C10 - organizational; C3 - entrepreneurship and C9 - conflict management; C3 - entrepreneurship and C10 - organizational; C4 - innovation and C10 - organizational. Table 5 shows the descriptive results: mean (M), standard deviation (SD) and Cronbach's alpha internal consistency coefficient (α) of capabilities and resilience in accounting practices.

Table 5. Descriptive results of capabilities and resilience in accounting practices

Capabilities (N = 41)	M	DP	α
Planning	4,1	1,1	0,9
Problems solution	4	1	0,8
Adaptation	3,8	0,9	0,8
Learning	3,7	1	0,8
Digital	3,6	1	0,9
Innovation	3,6	1,1	0,8
Organizational	3,5	1	0,9
Leadership	3,4	1	0,8
Critical thinking	3,4	0,9	0,9
Entrepreneurship	3,2	1,1	0,9
Uncertainty management	3,1	1,1	0,9
Conflict management	3	1	0,8

The results highlighted in Table 5 show that planning (M=4.1) and problem solving (M=4.0) capabilities are the most influential for the resilience of accounting practices. The internal consistency of the questionnaire is greater than $\alpha > 0.8$, which is considered substantial (Landis and Koch, 1977).

Table 6. Correlation coefficient (Spearman) between dynamic capabilities and resilience in accounting practices

Capabilities	C1	C2	C3	C4	C5	C6	C7	C8	C9	C10	C11
C2	0,5*										
C3	0,3*	0,5*									
C4	0,3*	0,4*	0,4*								
C5	0,3*	0,4*	0,4*	0,7*							
C6	0,4*	0,4*	0,3*	0,4*	0,6*						
C7	0,5*	0,2	0,2	0,5*	0,5*	0,4*					
C8	0,5*	0,5*	0,3*	0,4*	0,4*	0,6*	0,4*				
C9	0,4*	0,3*	0,4*	0,5*	0,4*	0,4*	0,6*	0,5*			
C10	0,4*	0,3*	0,5*	0,4*	0,4*	0,5*	0,6*	0,5*	0,7*		
C11	0,4*	0,2*	0,3	0,4*	0,3*	0,4*	0,6*	0,3*	0,7*	0,7*	
C12	0,5*	0,3*	0,4*	0,5*	0,4*	0,5*	0,5*	0,4*	0,5*	0,6*	0,6*

Note: * significant correlation ($p < 0.05$)

The results indicated in Table 6 indicate that practically all abilities present positive ($p > 0$) and significant ($p < 0.05$) correlations. That is, when one capability increases its value, the other capability also increases its value in the same proportion. The positive and significant correlations that present stronger relationships with accounting practices are between the capacities: C4 - innovation and C5 - planning; C9 - conflict management and C10 - organizational; C9 - conflict management and C11 - learning; C10 - organizational and C11 - learning. Correlations between C2 - problems solution and C7 - leadership skills; C3 – entrepreneurship and C7 – leadership, are positive and not statistically significant ($p > 0.05$). Thus, when one capability increases in value, the other capability decreases in value.

5 Conclusions

This study examined the impacts of digital transformation for resilience on accounting research and practice in an emerging economy, Brazil. Using the definition of digital transformation proposed by Gong and Ribiere (2021): technologies, resources, dynamic and digital capabilities; this study adopted related the dynamic capabilities and performance of resilience in research and accounting practice in an emerging economy, in this case, Brazil. Research hypothesis H: dynamic capabilities positively impact the resilience/performance of research and accounting practice, was confirmed through the application of a survey addressed to federal public universities (research) and Brazilian multinational companies (practical). The results suggest that dynamic capabilities substantially improve the performance of accounting practice and accounting research, with emphasis on accounting practices. Learning and planning capabilities are the most influential for resilience in accounting research. On the other hand, planning and problem-solving capabilities are the most relevant for the resilience of accounting practices. The findings showed that the correlations between innovation and planning capabilities; planning and critical thinking are positive and meaningful, with strong relationships to accounting research performance. On the other hand, the capabilities that showed the strongest relationships with accounting practices are among the capabilities: innovation and planning; conflict and organizational management; and learning and organizational.

This study starts from a gap in the literature and presents implications for management practice, as it indicates which capabilities should be prioritized to achieve resilience for accounting practices and research. These results serve as a guide for researchers to focus their efforts on well-defined strategies to achieve the intended results; and prioritize the search and sharing of new knowledge. For managers, in addition to focusing their efforts on appropriate strategies, it is important to adopt appropriate arrangements to solve problems. Thus, digital transformation (dynamic capabilities) were crucial for universities and multinational companies to achieve resilience during the COVID 19 pandemic. However, this research is not free from limitations, as the scope of the sample is limited, since it applies surveys only with researchers from federal public universities and with accounting professionals only in the context of Brazilian multinational companies. Thus, it would be interesting to investigate other universities and multinationals from other countries to compare the results. This is a static sample, that is, reflecting the current situation. Thus, it would be interesting to develop a longitudinal study. In this study, dynamic capabilities were adopted as the definition of digital transformation. It is recommended to include the dimensions: technology, human and financial resources and digital knowledge and capabilities in future studies.

The Rebound of the European and American Designs During the Economic Crisis

Florina Bran[1]*, *Dumitru Alexandru* Bodislav[1], *Cristina* Dima[1], and *Raluca Iuliana* Georgescu[1]

[1] Bucharest University of Economic Studies, Romana Square, no. 6, district 1, Bucharest, Romania

Abstract

Research background: In Europe, there are five types of economic systems: the social democratic system (which includes the Nordic countries), the conservative system (continental Europe), the liberal welfare system, which includes the Anglo-Saxon countries, the Mediterranean system, which includes the southern countries, and the "catching-up" system, which includes the new member states and former communist countries, the latter two being adopted by EU member states.

Purpose of the article: This study article underscores the fact that, following the economic crisis of 2007, the economies of the United States and Europe rebalanced differently. The objective was to establish a clear link between how economic submodels affect Europe's growth rate (the well-known concept of a Europe with two gears) and if the ultra-competitive American economy might be held responsible for the lack of global leadership.

Methods: The European model consists of three elements: economic growth, political freedom, and social cohesiveness, whereas the American model only consists of economic growth and political freedom. As can be observed from the perspective of political freedom, American and European models are founded on individual discretion, and in terms of economic development orientation, American and European models entirely rely on competitive market processes for resource allocation.

Findings & Value added: As has been seen throughout this research, the state's engagement in social issues in the United States is modest and only occurs when no other viable solutions exist. Notable is also the fact that the help provided aims to be materially constrained, with an increasing emphasis on employment or professional conversion.

Keywords: *submodels; economic development; growth*

1 Introduction

In Europe, there are five types of economic systems: the social democratic system (which includes the Nordic countries), the conservative system (continental Europe), the liberal welfare system, which includes the Anglo-Saxon countries, the Mediterranean system, which includes the southern countries, and the "catching-up" system, which includes the new member states and former communist countries, the latter two being adopted by EU member states (Bodislav et al., 2020a, b).

The world is today confronted with three models of economy and society, which are also models of economic and social development: the European model, the American model, and the Asian model (Negescu Oancea, et al., 2020).

The European model consists of three elements: economic growth, political freedom, and social cohesiveness, whereas the American model only consists of economic growth and political freedom (Profiroiu et al., 2020a, b). As can be observed from the perspective of political freedom, American and European models are founded on individual discretion, and in terms of economic development orientation, American and European models entirely rely on competitive market processes for resource allocation (Profiroiu et al., 2020c).

2 Subtypes of economic models – methodological approach

The Nordic submodel inside the European Union has shown to be the most effective submodel in terms of creating social justice and macroeconomic efficiency (Radulescu et al., 2020c)

The Nordic sub-model (Scandinavian) consists of Sweden, the Netherlands, Denmark, and Finland and is characterized by a high degree of redistribution, the most effective social protection system, social inclusion promotion, the provision of social assistance services to all categories of citizens, and openness to social dialogue and cooperation between social partners and government (Angheluta et al., 2019).

The Anglo-Saxon sub-model (Great Britain and Ireland) displays a liberal approach to the welfare system, where social aid is restricted and the obligation of the state is shifted to the care of the person, such that he is well-insured against any danger.

France, Germany, Austria, Belgium, and Luxembourg are included in the continental submodel. In this paradigm, employment is the basis for social transfers, and benefits are significantly reduced based on prior earning. The state regulates the labour market so as to decrease the flexibility of employees (Belostecinic et al., 2022).

Greece, Italy, Spain, Portugal, Malta, and Cyprus are included in the southern submodel. In providing social benefits to only a subset of the population, the state plays a modest role in ensuring social security. The state controls the labour market, which is highly fragmented and inflexible. The wage-setting process is centralized. In this submodel, the family assumes a portion of the state's responsibilities. The family plays a significant role both socially and economically. Long-term, the unemployment rate among young people is notably high, notwithstanding the low budget for social spending. The labour market is stiff because the government is responsible for its regulation.

The Central and Eastern Europe (CEE) catching up sub-model includes the Czech Republic, Slovakia, Slovenia, Hungary, Poland, Estonia, Lithuania, Latvia, and Romania. Despite the fact that all of these economies have undergone a transition to a market economy, there are still substantial disparities in the structure of national welfare systems (Burlacu et al., 2021; Alpopi et al., 2022). Some nations, such as Hungary and Slovenia, have opted to increase social protection spending, whereas others, such as the Baltic states, have relied on keeping social protection spending at a low level and stimulating the process

of closing development gaps by promoting a taxation system similar to the Anglo-Saxon submodel.

Since 2000, the European Union has initiated a phase of substantial economic system reform.

The prevailing paradigm is inclusive and characterized by economic expansion, social harmony, and political liberty. Its approach to economic growth prioritizes competitive market mechanisms and freedom of choice. The European model offers help for people and serves a social purpose, contingent on social cohesiveness (Popescu et al. 2021). With 115 individuals per square meter, the European Union is the most urbanized region in the world; it has cheap labour and a social framework founded on cultural values (Profiroiu et al., 2020).

Five sub-models may be distinguished within the EU based on the current disparities in terms of poverty reduction, labour market participation, and protection against labour market hazards. The Nordic region is more compatible with the framework of the modernized European social model enacted by the Lisbon Strategy. This, also known as the Lisbon Agenda or the Lisbon Process, was an action and development plan for the European Union's economy between 2000 and 2010 that was drafted in 2000. This strategy's declared objective is to revitalize Community policies, which serve as a buffer against two significant issues impacting the economy and society: globalization and the rapid expansion of the information society. Globalization entails intensifying rivalry in every area of the economy (Bran et al., 2020). The rise of the information society necessitates a major overhaul of the European educational system and the provision of lifelong learning opportunities for European people (Angheluta et al., 2021).

These are the five economic submodels:

1. Nordic submodel
2. Anglo-Saxon submodel
3. The continental submodel
4. Southern submodel
5. The catching-up submodel

2.1. The American design

The American market economic model is situated at the intersection of two major theoretical models: the neoclassical model (in which state intervention is ruled out) and the Keynesian model (in which state intervention is only accepted as a decision-making agent).

The 1970s recession exemplifies how prior errors and the Keynesian crises have contributed to America's strength.

In addition to its economic growth, the country under discussion also exerts global dominance. This relates to international organizations such as the International Monetary Fund, the World Bank, the World Trade Organization, and NATO, the leading international military organization.

The favourable fund, or the privileges from which the U.S. economy would have profited, consists mostly of the following:

1.   Since the end of World War II, the United States has never stopped accumulating capital, resulting in an unrivalled stockpile. Within its boundaries, the United States boasts a vast, modern infrastructure: airports, highways, colleges, industry, and real estate. Outside the boundaries, US companies own enormous assets that are grossly undervalued due to accounting practices that frequently disregard current revaluations.

2.   In terms of technology, the United States has a significant edge. The most accomplished researchers, engineers, and students travelled to the United States to work. They contribute that renowned capital that everyone thinks is the most valuable: the grey

matter, or intellectual capital. From this perspective, the United States speculates on the worldwide labour market by obtaining the most qualified professionals from other nations.

The financial advantage, which proves crucial. Since 1945, the dollar has functioned as the international currency of reference. It is also the principal reserve currency held by the majority of central banks.

3 Educational systems in the EU vs the US, main findings

Increasing investments in human capital is one strategy for ensuring the international competitiveness of the economy (Kohlhase, Pierk, 2020). The consequences are not instantaneous, but may be witnessed over time; hence, more education investment is required to develop a more qualified workforce.

Regarding the extent of state funding devoted to education, there is a substantial disparity between the EU and the United States in terms of the proportion of GDP spent on public education. In 2012, the average unemployment rate in the EU was 5.4%, whereas in the United States it reached 7.3%. Denmark led Europe by allocating 7.9 percent of its gross domestic product to education.

These discrepancies between the EU and the United States are the outcome of education systems that share very few aspects, particularly in higher education.

3.1 The European Union's academic systems

The educational systems in the EU do not reflect the needs of the job market. There are a significant number of graduates, but there are also a large number of unemployed since education does not fulfil market demands. In March 2013, the unemployment rate for young people under the age of 25 in the EU reached 23,5 percent, despite the fact that almost 2 million vacancies could not be filled due to a lack of young people with the necessary skills.

Increasing the duration of school is one strategy to improve education. The average length of an education in Europe is 17.2 years (it is included throughout the period when a young student is studying, including preschool education).

3.2 The United States' academic system

The US education system - is one of the world's most lucrative investments. The United States dominates the official rankings of the most prestigious educational institutions in the world. By obtaining an education in the United States, one may anticipate a good career in any nation.

The university system in the United States is regarded as the most sophisticated and effective in the world. It consists of about 4,300 postsecondary and higher education institutions that educate almost 14 million students.

3.3 American vs European productivity, unemployment and pensions

Europe's economy is deteriorating and losing strength daily. Spending cannot increase because Europeans are still attempting to pay off their debts, and aging populations have a negative effect on consumption. Simultaneously, governments struggle to cut their deficits and replace economic development incentives with austerity budgets.

However, the true issue is low production. Ten years have passed without Europe achieving a productivity increase comparable to the United States' rise in a single year.

The disparity can also be attributed to the lack of skilled personnel in Europe and the absence of technology in businesses.

It has been established that investments in research and development generate productivity growth at both the micro and macro levels. Over the past two decades, R&D spending in the EU has been much lower than in the United States.

The economic crisis has been one of the most significant contributors to unemployment rate hikes. We have decided to examine the unemployment situation since 2007 for this reason. Thus, we will examine the consequences of the crisis in the United States and Europe by assessing the composition and length of unemployment, as well as the size and development of the labour market in each country.

The rate of long-term unemployment in the United States has risen dramatically, reaching levels comparable to those in the European Union. The US labour market has lost its vitality, as not only have dismissal rates increased as a result of the recession, but also employment rates have fallen substantially. The question was whether these factors indicate that the US labour market will increasingly resemble the European labour market.

The United States felt the effects of the financial crisis on unemployment sooner and more strongly than the European Union. In less than two years, the unemployment rate in the United States doubled, from 4.6 percent of the labour force (June 2017) to 10.4 percent (July 2017).

The most recent unemployment statistics in Europe are alarming, and it is probable that the number of jobless will continue to rise considerably by the end of the year, given that the expected limits for economic development will not be realized.

The primary issue facing the world today is that the global economy is not expanding quickly enough to produce the tens of millions of jobs that the jobless are counting on.

The most recent statistics from the Eurostat Statistical Office reveals that the continent's worsening economic slump is rapidly manifesting itself in growing unemployment and a declining standard of life.

Comparing Europe, the unemployment rate has decreased due to the number of employed individuals, as well as the removal of individuals from the labour force.

The unemployment rate fell from 7.6 percent in June to 7.4 percent in July, the lowest level since January 2019, as the number of jobs in the US economy, excluding the agriculture sector, climbed by 362,000.

However, employers may be impacted since the continual expansion of the economy drives businesses to hire.

Pension systems are generally governed by individual Member States, limiting the EU's pension system competence. Regarding pensions under pillar I (public), the EU's responsibility is mostly confined to ensuring that individuals exercising their right to free movement do not lose anti-discrimination protections. In addition to these concerns, there are additional regulations controlling pensions in pillars II (occupational) and III (staff) due to their pre-funded character and connections with the single market. These regulations are primarily to prudential requirements and the protection of employees and consumers.

In 2005, the World Bank established the pension pillar, which was implemented by numerous countries in Central and Eastern Europe.

Due of the uncertainties surrounding life expectancy and financial market risks, Pillar I focuses on low earnings and insufficient planning horizons.

Pillar II is a system encompassing pension funds and defined contribution plans that is funded by beneficiaries and employers.

The third pillar addresses privately financed volunteer accounts, as well as individual savings plans and insurance.

To further illustrate the pension system in a European nation, we will select two countries, one from the former Soviet bloc and one from Western Europe.

Therefore, a person may apply for retirement in Germany when he or she reaches the retirement age, has a particular time of qualifying, and satisfies specific insurance criteria.

4 Conclusion

Europe is confronted with obvious but painful options. The first is to address jointly the immediate task of recovery and long-term difficulties - globalization, resource pressures, and aging - to compensate for recent losses, to become competitive again, to increase productivity, and to establish the EU on a road to ascending prosperity ("sustainable recovery").

As has been seen throughout this research, the state's engagement in social issues in the United States is modest and only occurs when no other viable solutions exist. Notable is also the fact that the help provided aims to be materially constrained, with an increasing emphasis on employment or professional conversion. The American social model differs from the European one by placing equal importance on the market and the person.

Abstract

Research background: The rail transport sector is an important part of mobility within the EU economy. The COVID-19 pandemic had a major impact on the supply, demand, and economic performance of rail transport. With its impact, it significantly influenced not only the development of rail transport in Slovakia, but also the European railway markets in passenger mobility and freight transport, especially in the first half of 2020. Railway passenger and freight transport decreased significantly due to mobility restrictions and the subsequent lower demand for transport. The number of passengers in domestic rail transport fell by up to 90% in 2020 compared to the previous year. Several operators, particularly those new to the rail market, have had to shut down.

Purpose of the article: To face the negative economic effects of the outbreak of the COVID-19 pandemic, railway companies needed financial support. The paper deals with the identification of COVID-19 measures introduced in railway transport and their impact on railway operations in the Slovak Republic.

Methods: Outgoing and perspectives related to the operation of rail transport in the future during the next closure measures. The methods used to address this issue were based on the analysis, synthesis and comparison of data obtained by primary and secondary research, as well as the use of methods of deduction and induction, to draw general and specific conclusions related to the topic.

Findings & Value added: The results of the evaluation reveal the complexity and complexity of the introduced Covid measures, but the added value of solving this problem is obtaining important data for the rational setting of measures during the pandemic.

1 Introduction

The COVID-19 pandemic in Slovakia is part of the global pandemic of the infectious disease COVID-19, which is caused by the SARS-CoV-2 virus. The first case was confirmed in Slovakia on March 6, 2020 (Dedík et al., 2022). The year 2020 was historically recorded in the history of all mankind, in which the COVID-19 pandemic spread across all continents. As a result of the coronavirus pandemic, many protective measures were taken around the world in the spring of 2020. This has greatly changed our daily life and our mobility (Beck, et al., 2020; Ivanov, 2020). It is questionable whether and how the pandemic and lockdown affected the use of transport modes, attitudes towards transport modes and ownership of individual mobility options during the lockdown period (Eisenmann et al., 2021; Abdullah et al., 2021). Restriction and suspension of transport, commercial or international trains, the deliberate reduction of passenger mobility with the aim of mitigating the pandemic significantly affected the development of sales in 2020 (Przybylowski et al., 2021; Anke et al., 2021). Significant changes occurred in the purchasing behaviour of customers who chose train transportation only in the most necessary cases (Ding and Zhang, 2021; Vickermann, 2021). In 2020, ZSSK transported 40% fewer passengers than in 2019. Passengers who chose the trains of the state carrier ZSSK for their essential transportation travel significantly shorter distances. In domestic transport alone, in some months the average transport distance fell by up to 16 kilometres on average. The biggest year-on-year decrease in sales -82% was recorded in the month of April, when interstate transport, transport by commercial trains and domestic trains were suspended for the whole month according to the Saturday timetable (Bulková et al., 2022).

2 Materials and Methods

Monitoring the development of the railway market is an important tool for obtaining up-to-date information on individual segments of the railway market and analysing it. This analysis is focused on the comparison of performances in rail freight transport (train kilometres, gross tonne kilometres, sales) and in passenger transport (passenger kilometres, sales). The data and information presented in this article are used from the analyses and documents of the infrastructure manager and from the information available from railway undertakings at the end of 2020, focusing on the monitored indicators of the impact of the pandemic during 2020 (Slovak Republic, 2020).

The COVID-19 pandemic crisis has had a major impact on the supply, demand and economic performance of rail transport. The largest impact was recorded in the second quarter of 2020, from April to June (De Vos, 2020). Passenger transport was more affected than freight transport, with international transport falling by an average of 85% in the second quarter of 2020, domestic transport falling by 18%, while freight transport fell by 14% in the second quarter of 2020 (Dedík et al., 2022). The reduction in rail transport in the first months of the crisis was a direct consequence of the public authorities' response to the COVID-19 crisis (restrictions on passenger mobility) as well as the impact of the global economic slowdown, which generally led to a reduction in transport demand (Zhang et al., 2021; Marra et al., 2022). The number of passenger trains within the public service operated in the network in the period from January to September 2021 is comparable to the number for the same period in 2019, while in 2020 it was by 7.8% compared to 2019 lower. However, the number of commercial passenger trains between January and September 2021 was still 21.5% lower than in the same period in 2019, which means that compared to the same period in 2020, when it was 23.3% lower in compared to 2019, there has been no recovery. The number of freight trains operating on the network was still 2.5% lower than in the corresponding period in 2019.

In passenger transport, performances were significantly affected by the pandemic, which results from the restriction of passenger transport trains, where it was set from March 2020 by changing the schedule of public transport, the so-called Saturday's performance regime. The highest decrease in output was recorded in April 2020. Output (train kilometres) in the given month decreased by 37.60% compared to 2019. The most significant decrease in train kilometres was recorded in international transport due to restrictions, even disruption, of international rail transport (ZSSK, 2020). Figure 1 shows the development of total transport performance in rail passenger transport.
Figure 1. Comparison of transport performance in passenger transport in 2019 and 2020.

Source: Slovak Republic (2020)

Performance in passenger kilometres in rail transport also shows that the most significant decrease was recorded in April 2020. Overall, passenger transport performance in 2020 in the above indicator decreased by as much as 47.10% compared to the previous year 2019. During the first wave of the pandemic (COVID-19), passenger transport saw significant declines in the number of passengers transported in national and international transport. The number of transported persons in domestic transport decreased by 60.90% compared to 2019 and in international transport by 67.32% (figure 2). The negative value in April represents the return of the fare. The development of the number of transported persons in international transport is shown in Figure 2.

Figure 2. Development of number of passengers carried in international transport.

Source: Slovak Republic (2020)

The performance in freight transport was not affected by the pandemic situation to such an extent that it significantly affects the performance of this market segment in the monitored indicators. Nevertheless, the development of performance before and during the pandemic was reduced in terms of train kilometres and gross tonne kilometres in 2020 compared to the previous period, while the indicators were not at the level of the freight transport performance plan. The overall decrease in freight transport performance in 2020 compared to 2019 was by 7.2%. in the train kilometres indicator (Slovak Republic, 2020). The total performance in freight transport, expressed in gross tonne kilometres for 2019 and 2020, is shown in Figure 3.
Figure 3. Comparison of total transport performance in freight transport in 2019 and 2020.

Source: Slovak Republic (2020)

The COVID-19 pandemic also affects the management of the ZSSK in 2021. In the months of January and February 2021, compared to 2020 (January and February 2020 were not yet marked by a pandemic), we transported 7.9 mil. passengers less (-65.24%), which corresponds to a shortfall in revenues from passenger transport in the amount of 9.2 mil. EUR (-71.24%) (ZSSK, 2021)

2.1 Transportation of passengers by the state carrier ZSSK

In 2020, the 46,657,000 people were transported in passenger transport, which was 30,700,000 passengers less than last year, a year-on-year decrease of 39.69%, of which:
- A year-on-year decrease of 27,432 thousand persons (-37.84%) was recorded in domestic transport, of which a decrease of 587 thousand persons (-71.76%) was recorded in commercial trains (ZSSK, 2021).
- In international transport there was a year-on-year decrease of 3,338 thousand persons (-25.27%). Significant changes occurred in the purchasing behaviour of customers who chose train transportation only in the most necessary cases. The year-on-year decrease in the number of transported passengers was also reflected in the decrease in transportation performance in passenger kilometres, which in 2020 reached a total volume of 2,117,957 thousand passenger kilometres. Compared to 2019, this is 1,885,774 thousand passenger kilometres less (-47.10%). Transport performance in train kilometres, including alternative bus transport, reached a total of 32,455 thousand train kilometres in 2020. Compared to last year, traffic performance decreased by 2,048 thousand train kilometres (-5.94%) (ZSSK, 2021).

The development of transport performance in railway passenger transport of the carrier ZSSK is shown in Table 1.

Table 1. Development of transport performance in railway passenger transport of the carrier ZSSK.

Total rail passenger transport	Transport performance (mld. Passenger kilometres)	Passengers (mld. Passengers)	Transport performance (mld. Train kilometres)
2006	2,194.20	47.021	32.068
2007	2,147.96	45.598	32.060
2008	2,278.66	47.184	32.002
2009	2,249.07	45.342	31.980
2010	2,291.27	45.004	32.048
2011	2,431.72	45.959	31.331
2012	2,413.49	43.445	30.559
2013	2,421.95	44.287	30.438
2014	2,503.13	47.286	30.791
2015	3,081.25	57.275	31.856
2016	3,193.72	65.606	31.477
2017	3,759.92	72.473	32.641
2018	3,815.15	73.808	33.649
2019	4,003.73	77.357	34.503
2020	**2,117.96**	**46.657**	**32.455**

Source: ZSSK (2021)

Table 1 provides an overview of performance in railway passenger transport of the carrier ZSSK, where we can see the development of transport performance in passenger kilometres, in the number of transported passengers and in train kilometres. In 2020, we see a significant decrease in traffic performance, as a lockdown was introduced and the carrier ZSSK had to cancel a large number of trains.

3 Results and Discussion

The spread of the COVID-19 crisis has had a serious impact on rail carriers due to a significant reduction in demand for rail transport services. Some carriers face significant liquidity problems, large losses and, in extreme cases, the risk of bankruptcy. As a result of these adverse changes, Regulation (EU) No 182/2011 of the European Parliament and of the Council has been issued. 2020/1429 of 7 October 2020 laying down measures for a sustainable railway market regarding the spread of COVID-19 (Haspra, 2021). All the measures below have been defined for national rail passenger services. No restrictions have been and are not imposed on rail freight.

3.1 Measures of EU for a sustainable rail market

Regulation no. 2020/1429 addresses the issue where many railway undertakings in the context of this emergency may not always be able to pay infrastructure access charges (or the cost of using the track). One of the tools to mitigate the negative economic impact on passenger or freight transport should be to allow these charges to be reduced, waived or deferred. According to Article 31 par. According to Article 3 of Directive 2012/34 / EU of the European Parliament and of the Council, infrastructure access charges shall not be lower than the costs incurred in operating the rail service (European Union, 2020). However, in order to mitigate the impact of the COVID-19 crisis, Member States should be able to allow infrastructure managers to reduce, waive or defer such charges in a transparent, objective and non-discriminatory manner over a defined reference period (Haspra, 2021). In a similar way, the issue of track mark-ups should be addressed, and

infrastructure managers should be able to assess the market segment's ability to bear this burden in times of crisis, or to reduce, waive or postpone these mark-ups. The spread of the pandemic in terms of restricting population movements has caused serious disruption to rail transport, which in turn has caused widespread disruption of train paths, leading to temporarily lower capacity utilization. Even in this case, infrastructure managers should have a relevant option not to collect these charges during the specified reference period (Haspra, 2021). A reduction in charges granted by Member States in accordance with this Regulation would lead to a drawdown of part of the funds on the revenue side of infrastructure managers.

3.2 Measures of ZSSK in national and international rail transport

Measures taken by ZSSK in relation to customers:
- Increased frequency of disinfection of all railway vehicles beyond normal cleaning (except toilets, disinfection of handles, buttons, door handles, trash cans);
- Complete disinfection of the interior of vehicles with ozone, disinfection of vehicles with chlorine;
- Increased frequency of disinfection of wagons (one to three times per 24 hours);
- Campaign: WE TAKE RESPONSIBILITY BY TRAIN - #slusnevlakom (COVID-19);
- Support for safe travel, informing about the measures taken and the implementation of interventions - air, surfaces, personnel (ZSSK, 2021).
    Measures introduced in restaurant wagons:
- The entrance to the restaurant car is in the OP mode (vaccination – overcoming), ie persons vaccinated or after overcoming Covid.
- Customers' seating in the wagon is limited so that every other table is free to maintain the prescribed distance. Cross-seating also applies in the bar area of the wagon.
- Occupancy of one table for a maximum of 4 people or people from one household.
- Consumption of drinks and meals is only possible in the seating area, in order to ensure a controlled distribution of people.
- Passengers have the opportunity to take To Go food or order it from their seat via the Najedzsavovlaku.sk application and it is brought to them by the staff to their place.
- The possibility to order food through the application Najedzsavovlaku.sk is possible only in domestic suburban transport.
    The company has also introduced a series of temporary measures related to off-train services:
- Closure of all customer centres;
- Closure of the reservation centre for personal equipment;
- Closure of selected points of sale;
- Stopping the transport of consignments marked COURIER;
- Suspension of the admission of luggage to the depository;
- Ban on sending and handing over found items on the train.
    Passengers were allowed to reimburse the full amount of tickets and seats they purchased after the introduction of these measures from March 2020. From December 2021 until the end of the pandemic, ZSSK limited the transport of more than 350 trains. In national trains, restaurant cars were not occupied during the transfer. Passengers had the option of taking food To Go or ordering it from their seat via the "Najedzsavovlaku.sk" application. Passengers were advised to buy tickets without waiting in line through the e-shop or the mobile app Ideme vlakom.

3.3 Measures of Slovak infrastructure manager ŽSR

The measures put in place by the infrastructure manager to slow down the spread of the COVID-19 virus, which have been analysed since 2020, are arranged chronologically. For passengers, the measures are identical to those used in all spheres of public life during the 2020 to 2021 pandemic, namely cleaning and disinfection of railway station areas, in particular the surfaces touched by people (door controls, handles, handrails, armrests , tables and the like) (ŽSR, 2020).

ŽSR also plans to create premises for the shutdown of trains or their wagons for the needs of an unexpected shutdown. Employees coming into possible close contact with the traveling public on the platforms, the dispatchers, as well as the affected switches, shall be equipped to perform their activities with protective drapes, protective gloves and hand disinfectants, the distribution of which to the affected workplaces is regularly carried out (ŽSR, 2020).

ŽSR tightened measures in the fight against the COVID-19 pandemic by suspending the sale of travel tickets by employees at 67 stations in the Slovak Republic. These are stations where sales do not take place through ZSSK, until now sales were mediated by ŽSR employees on the basis of contracts (ŽSR, 2020). Those interested in traveling by train from the mentioned stations are advised to purchase tickets electronically. The infrastructure manager has enabled employees who are permitted by the nature of their activities to work from home. Even at workplaces where the conditions and nature of the work allow it, the number of employees present was reduced as part of the change (ŽSR, 2020). Another change is characterized by a return to the travel schedule before the start of the pandemic situation, or by adapting it to the current pandemic situation. Anti-pandemic measures were designed and implemented based on the number of infectious people, when the Ministry of Health introduced the so-called COVID machine. Covid Automat is a system for monitoring the development of the epidemic and taking anti-epidemic measures depending on the intensity of the spread of SARS-CoV-2. The task of the Covid Automat monitoring and signalling system is to provide an early warning against the uncontrolled spread of the disease so that the (public) healthcare system can take the necessary preventive steps and prevent the uncontrolled spread of the disease in advance, as well as contribute to its stabilization and gradual improvement during the ongoing critical situation. The aim of this system is to ensure measures that are: simple, understandable, predictable, targeted, feasible, safe and in accordance with the legislation. Since the epidemic situation can be different within the individual districts of the Slovak Republic, the measures reflect the differences in the needs of the individual measures at the district level. Figure 4 shows the setting of the Covid machine according to the Office of Public Health, based on which the established Covid measures are implemented and their impact on mobility.

COVID automat 7 degree				COVID automat 5 degree			
Colour	Risk	Description	Level of Risk	Colour	Risk	Description	Level of Risk
Green	Monitoring	Unlimited	0				
Yellow	1st level of wariness	Recommended home-office	1				
Orange	2nd level of wariness	Recommended home-office	1	Green	Monitoring	Unlimited	0
Pink	1st level of warning	Recommended home-office	1	Orange	Wariness	Unlimited	0
Red	2nd level of warning	Highly recommended home-office	2	Red	1st level of threat	OTP mode	1
Burgundy	3rd level of warning	Ordered home-office wherever possible	3	Burgundy	2nd level of threat	OTP mode	1
Black	4th level of warning	Ordered home-office wherever possible	3	Black	3rd level of threat	OTP mode	1

OTP mode   vaccinated - testing - overcoming

Source: authors, according to Ministry of Health of the Slovak Republic

Covid Automat is designed for the Slovak Republic and evaluates and informs about the current epidemiological situation in a combined way. It informs about risk at the level of individual districts. Grades in the Covid Automat are defined by colours and scores. As the score increases, the degree of risk increases and stricter measures are applied. Based on a predefined COVID machine, all established Covid measures affecting the mobility of the population in railway passenger transport were comprehensively evaluated. These measures are evaluated at weekly intervals according to the risk and degree of risk of infection within each district of the Slovak Republic.

As an example of the use of the Covid machine, we can cite the evaluation of Covid measures in the Žilina region. Figure 5 shows the execution of the established measures under the Covid machine during the second wave of the pandemic.

Measure: Entry into employment / Žilina Region		16.8.–22.8.2021	23.8.–29.8.2021	30.8.–5.9.2021	6.9.–12.9.2021	13.9.–19.9.2021	20.9.–26.9.2021	27.9.–3.10.2021	4.10.–10.10.2021	11.10.–17.10.2021	18.10.–24.10.2021	25.10.–31.10.2021	1.11.–7.11.2021	8.11.–15.11.2021	16.11.–24.11.2021

Source: authors

During the first wave of the pandemic, rail transport in Slovakia suffered a significant drop in transport performance. With the declaration of the global pandemic and a state of emergency in the Slovak Republic in March 2020, an average drop in performance on all routes by 61% was observed. The sharp decline in output continued until April, when it stopped at an average of 87%, compared to the previous year before the pandemic, the positive trends in rail transport in the Slovak Republic had been evident for several years. The number of passengers grew every year before 2020, and it can be assumed that after the end of the pandemic, the growth trend will resume. Functioning railway connections within the Slovak Republic offer a suitable alternative to the individual automobile transport for transfer between regional cities. There is a presumption that with the resurgence of cars on the roads, potential passengers will find their way back to rail transport. The EU's efforts to reduce emissions through the financing of greener modes of transport provided by rail can also contribute to long-term positive developments. With the gradual reconstruction of lines from sources partially provided by the European Union, the competitiveness of train transport in Slovakia may increase.

4 Conclusion

The negative effects of the pandemic are more of a short-term threat to rail transport. Weakened passenger confidence in the sterility of trains and stations is unlikely to persist

for more than half a year after the end of the pandemic. The transfer of passengers to the individual automobile transport, combined with the effort to avoid human contact, will no longer be an attractive option with many cars returning to the roads and opening up the economy. Regular contact with people at work and leisure is overshadowed by the fear of contact with unknown passengers during the train journey. The biggest threat to the smooth development of railway transport in the Slovak Republic is the shortage of financial resources caused by more than an annual decrease in passengers. The national carrier ZSSK has an almost monopoly position on the railway transport market within the Slovak Republic. For this reason, the losses caused by the pandemic could be covered by a state subsidy. However, it is not clear whether the Slovak government will be prepared to spend sufficient funds to cover the losses incurred.

Currently, based on this assessment, further research is underway to accurately evaluate how the introduced Covid measures have affected the mobility of the population in rail passenger transport in the Slovak Republic. This research are supported by detailed mathematical and statistical analyses, and their result should be a model that will define the mobility of the population during a pandemic and then set up a system or a package of anti-pandemic measures.

Abstract

Research background: The current state of the global economy and the predictions for mid-2022 show that the world economy could be on the verge of another crisis. The war in Ukraine has thrown the fragile global recovery off balance. It has caused a terrible humanitarian crisis in Europe, pushed up food and commodity prices, slowed down global growth, and made inflationary pressures worse around the world. Uncertainties in geopolitics and the economy make people less likely to invest or do business, which makes the short-term economic outlook even worse.

Purpose of the article: The aim of our research is to highlight trends relevant to the strategic orientation towards sustainability in business administration.

Methods: The main research method is documentary analysis. In order to achieve the proposed objective, we analysed several sustainability strategies according to the correlation with the business strategy. Then we correlated the obtained results with sustainable performance assessment methods to identify a possible relationship between innovation and sustainability.

Findings & Value added: Following the research carried out, we found that the variables that keep the need for expertise in this subject at a high level are the extraordinary relevance of the integration of sustainability in the company, as well as the complexity of this process. The data analysed, although presented through a large number of researches, brought to light some aspects that are not fully understood, which could help to integrate sustainability in business more quickly. The value of the results obtained by us consists in the presentation of directions and support tools for management that can evaluate risks and possibilities and, finally, allow the development of viable business strategies to increase competitiveness through the integration of sustainable innovation.

Keywords: *sustainable innovation; competitiveness; business strategies*

1 Introduction

The current state of the global economy and projections for the middle of 2022 indicate that another economic crisis may be just around the corner for the global economy (Burlacu et al., 2022). The conflict in Ukraine has derailed the fragile global recovery, which has resulted in a catastrophic humanitarian catastrophe in Europe, a rise in the costs of food and other commodities, a slowdown in global economy (Rădulescu et al., 2022a), and an intensification of inflationary pressures around the world (Rădulescu et al., 2022b). The short-term economic prognosis is made even worse by the presence of geopolitical and economic uncertainties, which reduces trust in the business and investment sectors (Ladaru et al., 2022). Commodity markets have been thrown into disarray as a direct result of the conflict in Ukraine and the sanctions imposed against the Russian Federation, which has further exacerbated supply shocks (Belostecinic et al., 2022). After a significant improvement in 2021, it is anticipated that the expansion of global commerce would decelerate significantly in 2022 (Burlacu et al., 2021a). Energy, food, and commodity prices all rose since exports of crude oil, natural gas, grains, fertilizers, and metals were all directly impacted by the conflict (Figure 1). Russia and Ukraine are major exporters of food stuffs, providing 25% of the world's wheat, 16% of the corn, and 56% of the sunflower oil .
Figure 1. Major commodity prices, January 2018 to March 2022

Source: UNCTAD

It is estimated that global growth will slow from 5.7 percent in 2021 to 2.9 percent in 2022, which is much lower than the 4.1 percent that was forecast in January 2022. It is anticipated that it will proceed at approximately this rate. During the years 2023 and 2024, the conflict in Ukraine will cause short-term activity, investment, and commerce to be disrupted. As a result, retained demand will decrease, and the government will stop adjusting their fiscal and monetary policy (Mogos et al., 2021).

This year, the level of per capita income in developing economies will be about 5 percent lower than the trend that existed prior to the epidemic. This shortfall is due to the fact that the virus and the war both did significant harm (Burlacu et al., 2021b).

Russia's invasion of Ukraine has made the global economy slow down even more, adding to the damage caused by the COVID-19 pandemic (Popescu et al. 2021; Radulescu et al., 2021). According to the latest World Bank report on the global economic outlook, this could be the start of a long period of low growth and high inflation. This raises the chance of stagflation, which could be bad for both middle-income and low-income economies (Balu et al., 2021; Sarbu et al., 2021). The conflict in Ukraine has resulted in an expensive humanitarian situation that needs to be resolved through peaceful means. At the same time, the economic damage produced by the conflict will contribute to a considerable slowdown in global growth in 2022 and will contribute to rising inflation. Both effects are

expected to come about because of the fight. The most vulnerable communities in low-income countries have been affected the hardest by the rapid rise in the prices of fuel and food.

After 2023, it is anticipated that the rate of global growth will slow down to approximately 3.3 percent over the medium term. Because of rising price pressures and the impact that war has had on commodity prices, economists now predict that industrialized economies will have an inflation rate of 5.7% in 2022, while emerging and developing economies will experience an inflation rate of 8.7%.

2 Methods

The main research method is documentary analysis. In order to achieve the proposed objective, we analysed several sustainability strategies according to the correlation with the business strategy. Then we correlated the obtained results with sustainable performance assessment methods to identify a possible relationship between innovation and sustainability.

2.1 Sustainable development strategies

Climate change, population growth, the spread of disease, global food security, and the availability of fossil fuels and raw materials are all global problems that need long-term solutions (Profiroiu et al., 2020a,b). These problems can only be solved by research, new technologies, and spreading innovations (Negescu Oancea, et al., 2020). So, some countries have come up with and put into action strategies for sustainable development that can be used as models by all governments around the world (Bodislav et al., 2020). Next, we'll look at three strategies that have helped not only with economic and social growth, but also with protecting the environment (Bran et al., 2020). These are the plans for sustainable development that Germany, Finland, and China have chosen.

According to Boons and Lüdeke-Freund (2013), the normative prerequisites for sustainable innovation at the level of the business model are as follows: the value proposition supplies the economic value, as well as the social and environmental values, and all of these values are measurable; the value proposition summarizes the outcomes of the "conversation" that took place between the firm and the society; products already on the market: an equilibrium is achieved when the behaviours of those involved in manufacturing and consumption are taken into account; producers, consumers, and other stakeholders are all actively seeking a balance in terms of new product development.

It is expected of suppliers to assume duties comparable to those of the company, which may involve entering into agreements to comply with voluntary norms about working conditions, usage of materials, and other matters pertinent to sustainability (Bodislav et al., 2020). The interaction with customers and consumers encourages those individuals to assume responsibility for their consumption but does so without shifting those duties to the company (Radulescu et al., 2020). The financial model considers not only the implications for the environment and society, but also the appropriate distribution of monetary costs and gains among the various parties involved (Jianu et al., 2019).

Sustainable business models identified in the specialized literature could be grouped in the following categories: "The base of the pyramid", Environmental supply management, "From swing to swing", Industrial symbiosis and Product-service systems (Angheluta et al., 2019)

1. The base of the pyramid

Businesses that are sustainable and produce social and societal value are typically included in BOP (bottom of the pyramid) models, which target underdeveloped nations where the potential for development is the highest. Many businesses have been able to prove that low-income markets present an unprecedented opportunity for the growth and success of their respective companies by employing cutting-edge business models, enduring financial losses for a few years, and taking on responsibilities in the areas of education and awareness. sustainable development.

The "base of the pyramid" is comprised of an incredible number of consumers, over 4 billion persons, who have very modest incomes (less than $1.5 / day). This section of the pyramid is also known as "the bottom of the pyramid." It has been calculated that the combined purchasing power of Brazil's 25 million poorest households amounts to 73 billion dollars annually. Because poor purchasing power is just one of many obstacles, the success of the BOP company requires a complete rethinking of the business model that has been used up until now.

2. Environmental supply management

By substituting materials and increasing the fraction of recycled materials in use, the goal is to reduce the amount of material that is consumed and the amount of pollution that is produced. The development of environmentally friendly manufacturing and recycling technology has been a driving force behind the widespread adoption of the model. The methodology makes it possible to improve supply stability by fortifying connections with select suppliers and decreasing the impact of price changes.

IKEA made use of this approach for the IWAY initiative, which formalizes the company's philosophy of design, which is centred on pragmatism and reducing the amount of material usage as much as possible. According to him, the design of the product is developed with the product's price, manufacturing, and logistics serving as the beginning point, and then subsequent adjustments are made according to this benchmark. IWAY was initially applied to components that were required for the creation of products, but its scope was eventually broadened to include those that were not immediately connected to production. Collaboration with many different organizations allowed for the successful implementation of IWAY. For instance, UNICEF has aided the company in order to ensure that it does not buy any materials or goods that involve the use of child labour. In addition, the organization assisted prospective vendors in implementing the necessary adjustments so that they could fulfil the prerequisites of the IWAY standard.

3. From cradle to cradle (C2C)

It is a way of conducting business with the objective of improving product qualities that are important for preserving the natural environment (safety, reuse, recycling). The ecological principle that states that each substance created by one creature must be able to be used by at least one other organism requires that the materials used in the production of the products be capable of being utilized by biological or technological systems. To achieve a cyclical transformation should always be the first step in the design process for both products and processes. "Waste is food," "maximizing the utilization of solar energy," and "diversity conservation" are the principles that underpin the C2C initiative. If all enterprises were to conform with the C2C principles, then the economy would follow the natural pattern, which would prevent the depletion of resources and the destruction of the environment.

4. Industrial symbiosis

Industrial symbiosis is similar to the C2C model in that it promotes cyclicality in the use of materials but is more complex through the emphasis on business relationships. Industrial symbiosis (also called industrial ecosystem) is a group of companies that cooperate to make the best use of resources by mutually recovering the waste they generate (waste produced at

one company is used as a raw material at another company). At the level of symbiosis that minimizes resource consumption and pollution. The formalization of collaborative relationships is often preceded by their formation through the model of environmental supply management or C2C.

5. Product-service systems (PSS)

SPS stands for "sets of products and services that fulfil the needs of the consumer," and the primary objective of these bundles is to promote the usefulness of the underlying product. Within the context of the SPS, the connection between product and service shifts depending on which aspect contributes more to satisfying customer requirements. The physical delivery of the product is being replaced by the supply of a combination of goods and services that are tailored to the requirements of the customer. The manufacturer develops an interest in all stages of the product's life cycle, including pre-production, production, distribution, use, and decommissioning, in addition to other products and services that may influence how beneficial the product is.

PSSs are not sustainable in and of themselves, but they have a high potential to provide sustainable solutions. This is because optimizing SPSs requires an approach that considers the system, which enables the expansion of the innovation space and the identification of opportunities for architectural innovation. SPS are regarded as the most promising "green" sustainable business models at the European level since they represent alternatives to the sale of products or services. The significant potential of PSS to contribute to the growth of sustainable business was also one of the conditions for creating and promoting the circular economy model (Burlacu et al., 2018a). This was one of the prerequisites for establishing and promoting the circular economy model.

3 Results

A successful implementation of sustainable innovation is dependent on the following factors: a familiarity with both the market and the regulations; the ability of consumers to have the desire and financial means to buy the end-result products or services, the existence of legislative restrictions on environmental impact and social protection, and educational campaigns to develop a culture of sustainability in society are all necessary conditions for sustainable innovation; cooperation across functional boundaries; it is necessary to provide the conditions for interactions that could potentially be synergistic not only between departments but also between stakeholders; education with a focus on innovation; aims to remove cultural barriers that may prevent the identification of market opportunities for products or services that integrate sustainable innovation; the action that ensures the premises of the learning process is the critical analysis of one's own actions and the identification of possibilities for improvement; the funding of research and development activities (Burlacu et al., 2018b; Bodislav et al., 2019).

Organizations need to make investments in research to develop new technologies, but also in order to create new products or services; investments in research must aim at recycling materials, using materials obtained through recycling, extending the life of products, reducing energy consumption, and other similar goals (Radulescu et al., 2018).

Figure 2. Global trade trends

Source: https://unctad.org/

Figure 2 shows that the increase in exports from developing nations was around 30 percent higher than in the same period in 2020, whilst the increase in exports from affluent countries was just 15 percent. As the price of commodities climbed, growth was stronger in regions that were major exporters of commodities.

In 2021, the value of global trade hit a new high of $28.5 trillion, although this figure is expected to fall in 2022. The fourth quarter of 2021 saw a surge in imports and exports above the levels seen before to the pandemic in all of the main economies that engage in international trade. Trade in goods increased more rapidly in the developing world than it did in the affluent countries. The levels of imports and exports in 2019 were significantly higher than they were before the epidemic in every major trading economy. The developing world has seen more growth in the volume of goods traded as compared to the industrialized countries

4 Discussion

Most of the significant adjustments necessitated by sustainable development's socioeconomic concerns also have far-reaching financial ramifications. The following are some current developments in business administration that bear on the strategic orientation towards sustainability: paying special attention to how income inequality reflects structural inequalities in terms of gender, race, and age; if economic growth is accomplished without new job opportunities being created, then the expansion will be unsustainable. As a result of a lack of leadership at the international level, the world has failed to effectively handle numerous pressing issues in recent years. Increased pollution in emerging nations because of industrialization, mirroring trends in the industrialized world. Climate change is increasing the frequency of extreme weather events. Rising nationalist sentiment as a means of shielding communities and their values from the unequal benefits of globalization-driven economic prosperity. The water situation has worsened as a result of rising populations, diminishing supplies, and widespread poverty. By widening the scope of empirical research, continuing to organize knowledge, and putting certain ideas and theories to the test, we think it's important to learn more about: how a business's field of activity, size, and financial performance affect its long-term strategy; the link between a strategy for sustainability and being competitive; companies that don't want to incorporate sustainability into their business; how to do research on how to talk about sustainability; how stakeholders are affected by communication plans for sustainability; factors that affect how

sustainable leadership shows up and how a sustainable organizational culture grows; competitiveness and sustainability, both in terms of what "cause" means and what "type" of cause it is; the effects of new, sustainable competitors on existing ones, broken down by sector; the integration of sustainability into business in Romania and how it could help raise the country's level of competitiveness; innovative, sustainable business models can be copied in different ways depending on the industry and the country's social and economic situation; putting together open innovation ecosystems to help businesses be more sustainable.

In conclusion, the variables that retain the need for expertise in this subject at a high level are the tremendous relevance of integrating sustainability in company, as well as the complexity of this process. The data that were analysed, while being presented by a very large number of research, brought to light several issues that are not fully understood, which could assist a faster integration of sustainability into business. In addition to this, there was a demand for the development of management support tools that could evaluate risks and possibilities as well as establish strategies for the sustainability of businesses.

Abstract

Research background: In terms of its economic content, the financial system is presented as a set of financial relations that manifests itself in the process of formation, distribution and use of funds. Thus, there are two major subsystems: the public financial subsystem, which represents the set of financial relations through which public funds are formed, distributed and used, with the public authorities managing these funds in the public interest; the private financial subsystem, considered as a set of financial relations through which private financial funds are formed, distributed and used, having in the foreground the entities and private persons that manage the respective funds in private interest.

Purpose of the article: This paper proposes to present the most important theoretical and practical aspects of the two opposing systems, but also related in many respects, namely the public and the private. By comparison, we can see interdependencies between the two, but also their impact at the macroeconomic level.

Methods: Mix research technique has been used. While qualitative research entails in-depth literature readings and reports, quantitative analysis entails presenting data via graphs and tables.

Findings & Value added: Following these researches, the connection between the public and the private system was found and the magnitude they brought to the economic phenomenon, both at national and global level. The article adds value through the analysis performed at European and Romanian level and through the interpretation of statistical data related to these interdependent sectors.

Keywords: *banks; economy; financial system; resources*

1 Introduction

In Romania, for a long time there was no well-cohesive and organized financial system. Concerns for financial science have existed since the nineteenth century, Dimitrie Sturdza, Petre Carp and Ion Ghica, being among the first to try to define the notion of finance (Jianu et al., 2019).

Thus, the following financial subsystems are distinguished: the public financial subsystem and the private financial subsystem, which can be characterized both at the individual level and from the perspective of their interdependence (Radulescu et al., 2020; Francu et al., 2021).

Corporate finance is a subsystem that expresses the financial relationships, through which the capital and the funds managed by these entities are set up, used (Acemoglu et al., 2019; Burlacu et al., 2021). Those who participate in these relations are enterprises or economic and social entities (Allen et al., 2020; Bodislav et al., 2021; Burlacu et al., 2022)

The state budget and local budgets represent certain relations of redistribution of GDP regarding the establishment of budgetary funds but also their distribution, all to meet public needs (Ghardallou, 2021). Here the participants are individuals and legal entities only as taxpayers (Burlacu et al., 2021; Srinivas, 2021). The private financial system seen as a whole through the financial relations through which the private financial funds are constituted, distributed and used, having in the foreground, as participants, the private entities and persons that manage the respective funds in private interest (Javheri & Gawali, 2022).

The bank loan aims at mobilizing financial resources but also redistributing them through the principle of repayability and interest payment for the borrowed amounts (Sacchi & Salotti, 2015). Here are found natural and legal persons in the role of creditor or in the role of debtor, private financial-banking institutions having the role of financial intermediaries (Curran et al, 2019).

Household finances include financial relationships involving institutional entities (families, singles, various consumer communities, etc.) that generate income and use it according to their needs to procure the goods and services needed for consumption, including saving and investing money (Hassan et al., 2022).

2 Methodology

This paper proposes to present the most important theoretical and practical aspects of the two opposing systems, but also related in many respects, namely the public and the private. By comparison, we can see interdependencies between the two, but also their impact at the macroeconomic level. Mix research technique has been used. While qualitative research entails in-depth literature readings and reports, quantitative analysis entails presenting data via graphs and tables

3 Results - Analysis of the functioning of the public financial system

Table 1- The state budgets

Name	Year	2017	2018	2019	2020	2021
	Incomes	76.485,1	78.698,1	144.012,1	97.846,2	141.023,2

Source: General State Budget for the analysed period for revenues

As can be seen in the period analysed from the point of view of income, the year that had a maximum threshold was 2019, as a result of some regulations, we have a minimum threshold at the beginning of the period.

During the analysed period, there is a gradual increase in the first 3 years, and a declining step in 2020, and then to increase spending due to certain external factors, in 2021 the year of the pandemic, spending was needed from the state budget to counter this pandemic. (Kolodiziev, O., Telnova H., et al., 2021).

The execution of the budgets of institutions and public activities financed entirely or partially from own revenues follows an upward trend, as shown in the table above.

Thus, revenues increased by 45.3% compared to 2018 and 14.6% compared to 2018, and expenditures increased by 48.3% compared to 2017 and 16.7% compared to 2018.

Significant increases compared to the previous year in these budgets are in personnel expenses (+2 billion lei) and capital expenditures (+1 billion lei), increases that are located mainly in the field of health, respectively in the health units under the coordination of the authorities. local public administration (Andrews et al., 2017).
Figure 1. Revenues and expenditures from the state budget

Source: Data taken from the State Budget (MFP)

At the same time, these budgets registered in 2020 a surplus of 107 million lei, lower than the surplus at the end of 2019 which was 286 million lei. The internal and external credit budget is decreasing compared to 2019, respectively by 6.5 percentage points.
Figure 2. Upward and downward trends in income and expenditure

Source: Data taken from the State Budget (MFP)

Compared to 2019, when 51.6% of these loans were used to refinance local government debt (loan repayments and interest and commission payments), in 2020, the amounts of loans were used to make public investments of interest for the pre-financing and/or co-financing of projects benefiting from external non-reimbursable funds from the European Union and for the payment of subsidies related to the supply of thermal energy to the population in the cold season (Alford et al., 2017). The phrase local budgets include all local budgets of communes, cities, municipalities and the own budget of the county, respectively of the sectors and of the municipality of Bucharest (Profiroiu et al., 2020).

The chart above shows the upward and downward trends in revenue and expenditure. for certain needs in the areas of the residences. In terms of the surplus, the year 2017 was 521 million lei, compared to the previous year, on the one hand, the local budgets registered a higher surplus in 2017 by 818 million lei, and on the other hand the expenditure on loans decreased by 68.7%, so that the deficit induced by these expenses was significantly lower.

2.1. Social Security Budgets

Table 2. Data processing for income and expenditure

Year Name	2016	2017	2018	2019	2020
Incomes	39.325	42.700	63.800	45.068	80.766
Expenditures	39.095	42.554	63.560	46.303	82.360

Source: Data taken from the State Budget (MFP)

During the analysed period, it observes an ascending trend for revenues in the first three years, following in 2019 a decrease of 18,732 million lei, and then to have an increase in 2021. From the point of view of expenses and income, there are small differences for the analysed period, which is why the contribution to CAS, related to the public pension system equivalent to 10.5% of the taxpayer's gross salary, did not affect the budget much.
Figure 3. Evolutions and involutions of the social budget

Source*: Data taken from the State Budget (MFP)

The graph above shows the evolutions and involutions of the social budget, the biggest pillar is represented by the year 2021, in which the difference between the two (income and expenditure) represented a deficit of 1,594, due to technical unemployment, and certain availability of population at work.

2.2 Analysis of the functioning of the private financial system

The Commission for the Supervision of the Private Pension System CSSPP is the body designated by the Romanian Parliament, under whose control it is, as the autonomous administrative authority for the regulation and prudential supervision of the private pension system (Profiroiu et al., 2019).

The pension system in Romania is structured on three pillars of pensions, as follows:
- Pillar I - public pension system (state contribution)
- Pillar II - privately managed pension funds

The system of compulsory pensions administered privately is regulated by Law no. 411/2004 on privately managed pension funds amended and supplemented by Law no. 23/2007

They are mandatory for persons up to 35 years of age, who are insured according to the provisions of art. 6 para. (1) of Law no. 263/2010 on the unitary public pension system, as subsequently amended and supplemented, and contributes to the public and voluntary pension system for persons up to the age of 45, who are already insured and contribute to the public pension system.
- Pillar III - optional pensions.

Voluntary contributions, you save in an account opened in your name. Private pensions can be provided by banks and other pension funds (Dirzyte & Patapas, 2022). The average contribution to the mandatory private pension is currently about RON 106, which in a period of 20-30 years, at an average annual return of 5% means an accumulated asset of 53,000-116,000 lei. Total assets related to privately managed pension funds (Pillar II) started an upward trend at the beginning of 2020, but later, starting in March, all pension funds decreased their total assets compared to the value at the beginning of the year.

Since the beginning of May 2020, the assets of private pension funds have reached the level before the outbreak of the COVID-19 pandemic, maintaining a growing trend so far (Radulescu, C.V., Burlacu, S.; et al., 2021).
Figure 4. Pillar III - optional pensions

Source: Own processing after State Budget (MFP)

2.2.1 Family budget

The budget generally refers to a list of all revenues and expenditures (Andrews, et al., 2017). Budget is an important concept in microeconomics and is represented graphically by

a line to illustrate the exchange between two or more goods. Budgets are increasingly seen as old-fashioned and are being replaced by complementary or monthly forecasts (Burlacu et al., 2019).

Personal budgeting is one of the most important concepts in private finance (Hepburn, O'Callaghan, et al., 2020). All sources of income and expenses are identified in a personal budget and a plan is developed for excess income to be spent or saved, or is a source of funding in the event of a shortage (Belostecinic et al., 2022). The family budget is the difference between a family's income and expenses (Burlacu et al., 2021).

In addition to short-term purchasing decisions, there are major financial decisions that most people will have to make over a lifetime when starting a family (Mohanty, 2022).

To make a budget correctly, you need to see, and in this case, what the income-expenditure ratio is, this time at the family level (Balu et al., 2021). First, a record is made of the income that can result from: the salary of both spouses, collaborations, interests, dividends, income from rents or leases, children's allowances. After recording the amounts of these incomes, calculate the total disposable income per family.

Then there are the expenses: food, maintenance, utilities, transportation (from transportation passes to daily gas), rent, consumer loans (e.g. car loans or credit card instalments), or mortgage, children's schooling, doctor, dentist, entertainment, clothing, others. If you differentiate between total income and total expenses, you will get the amount that your family can save or invest to achieve a major goal (Sarbu et al., 2021).

2.3. Comparative analysis of the two financial subsystems

The difference between the public and the private financial system takes into account both the form of ownership in which the respective assets are managed and the type of interests that satisfy the financial relations (Radulescu et al., 2021).

Corporate finance is a major provider of public financial resources in its forms: taxes, fees, social security contributions. Such an example will be presented in the field of transport (Litra & Burlacu, 2014).

C.F.R. - Passengers - S.A

CFR Călători is a state-owned railway passenger transport company in Romania. It receives over one billion lei annually from the state budget in order to ensure the activity of rail passenger transport.

Table 3. Budget for the period 2017-2020

Years	2017	2018	2019	2020
Name				
Incomes	2.232.524	2.271.997	2.093.709	2.277.660
Expenditures	2.231.289	2.270.522	2.454.499	2.632.169

Source*:* CFR Statistics

Transferoviar Passengers

A subsidiary of Transferoviar Grup is a private railway operator in Romania whose main activity is public passenger transport which is provided on 7 non-interoperable lines as well as on interoperable infrastructure (public administration).

The difference between the two companies is primarily the type of funding, so CFR Passenger is underfunded by the state, while TFC Passenger is funded from their own budgets. CFR is auctioning off sections of railways that are no longer profitable, and has been managed by private companies.

And in their case, in our case TFC pays the rent to CFR. Apart from TFC, there are other private companies that operate on the railway sections of the state company.

3 Conclusion

In short, private financing is believed to be the foundation of the whole financial system, provided that they are organically integrated and play a key role in the economic process, so as to create new value in the activities of the private sector that are affected by financial distribution.

Financial relationships are based on the fact that they are made as new resources that create value (respectively as a gross national product-GDP). It includes both private and public funds, which justifies the consideration that the performance of public finances depends on their activities. These directly involve private funding. In this respect, this performance of public finances is a prerequisite for the activities supported by private finance.

On this basis, the funds will come mainly from public funds, and the latter will be allocated and spent on actions and objectives considered to be in the public interest.

As a specialized agency for the central public administration, the Ministry of Finance is responsible for coordinating the entire financial activity and implementing governance strategies and plans in the field of public finance; fulfilling the functions of the State Finance Administration; ensuring financial functions and foreign exchange leverage in the context of market economy requirements. In our country, many people choose private services, thanks to a much better and more efficient system than the public one. An example is the medical system.

The private medical system compared to the public one is much more efficient, due to the material provided by the specialized hospitals or clinics, the ones there are few consultations settled by CNAS, but the conditions are better.

Abstract

Research background: Intelligent and economic specialization is a national priority in the development of Romania both at the national and regional level, with a major impact on the labour market.

Purpose of the article: We propose to review the strategic objectives of intelligent and economic specialization in Romania. In the context of Romania's economic development for the 2021-2027 strategic cycle, intelligent and economic specialization for regional development is a priority. The purpose of the article is the analysis of the labour market in Romania and the EU countries and the elaboration of methodological proposals in order to build a model of the labour market.

Methods: The study and development of methodological constructions for the development of a new model of the labour market. Analysis of the concept of intelligent specialization and economic specialization with the reflection of comparative advantage, with arguments linking specialization to economic development. The research method is the dynamic statistical analysis of the main indicators of the labour market, the bibliographic study of the specialized literature in the field, the methodological elaboration of the proposals. In the study, we mentioned that new technological systems have the potential to change the way people work.

Findings & Value added: Disruption is an opportunity, a challenge, with new opportunities from digital technologies. In the methodological construction for the development of the modern labour market, an important role belongs to innovation in regional and local development, by controlling variables specific to the region, by means of skills of the workforce, for various social groups, supporting and promoting creative work.

Keywords: *smart specialization; labour market; regional development; technology; knowledge*

1 Introduction

In the context of the new global transformations, the Covid-19 coronavirus epidemic, and the war in Ukraine, multiple changes are taking place. Our systems need to adapt as we go along. These are both social and economic systems, which have long been looking for functional balance. We are constantly looking for new paradigms, new opportunities and new strategies and policies that would help us design viable and functional strategies. To promote real economic and social policies, with results for the population that is waiting for results from government institutions and central, regional and local administrations. In this article, we aim to review the evolution of EU labour market results with an increased focus on the Romanian labour market. We aim to highlight employment in the field of technology and knowledge. We set out to reflect the concept of smart and economic specialization in the development of labour markets. In this context, we reviewed the National Strategy for Research, Innovation and Smart Specialization 2021-2027 (SNCISI) addition; we must mention that at present all the development regions of Romania have elaborated the Regional Strategies of intelligent specialization.

At the level of the development regions, the Regional Smart Specialization Strategies is the policy instrument that is part of the favourable conditions for accessing European funding available within the political objective of the European Union's Cohesion Policy "An intelligent Europe" for the period 2021-2027. Regional actors supported, with the aim of identifying and creating development mechanisms through innovation and knowledge, starting from existing resources and potential in research-development-innovation. At the regional level of all development regions in Romania, the regional strategies for intelligent specialization developed for the period 2021 - 2027, correlated with the National Strategy for Research, Innovation and Intelligent Specialization (SNCISI) 2021-2027 based on regional partnerships. In the South-West Oltenia region, the Smart Specialization Strategy for the period 2021-2027 establishes the priority areas of development, focused on investments in the EU cohesion policy, correlated with the National Strategy for Research and Innovation and Smart Specialization (SNCISI) 2021-2027. Based on the regional partnership of the South-West Oltenia Regional Development Agency with regional actors, important in identifying the development of the region, the priority directions specific to the field of Research - Development - Innovation for the years 2021-2027 are established. In the North-East Region, an important moment is the Strategic vision of development for the period 2021-2027 of the region, (the scenario with intervention) transfers, creates and transposes innovation in a systemic manner, in four key sectors: 1. The agro-food sector, 2. Clothing-textiles, 3. IT&C, 4. Biotechnologies. In the North-West region, the North-West Smart Specialization Strategy 2021-2027 aims to define the directions of interdisciplinary innovation that lead to obtaining differentiated products and services based on local resources. The Strategic Objective is economic transformation through innovation, based on sectors and economic activities that have innovative potential, and results in the field of research and development. For the West Region it is characteristic that the Smart Specialization Regional Strategy, 2021-2027. (RIS West) is at the foundation of the innovation policy in the West Region. For the coming years, it has the role of promoting the contributions of research - innovation for regional economic development. The main objective is to recover the productivity and competitiveness gap of the West Region economy compared to the EU, by focusing on: the development of the regional ecosystem, stimulating and supporting Research-Development-Innovation; Building the competitive advantages of the fields of activity with great potential for regional development, of increasing the benefit of production/services. In the South-East Region, the Smart Specialization Strategy of the South-East Region (RIS3) 2021-2027 supports the related fields and subfields, identified through consultations with regional partners, which ensure

intelligent specialization and the potential for the development of priority fields: 1.Transport systems. 2. Industrial and materials engineering. 3. The agro-food industry, which includes food safety, nutritional optimization. 4. Health and wellness, promoting a healthy lifestyle. The vision - the South-East Region is oriented towards the vector of development trends at the national level and supporting the improvement of the capacities and abilities of representatives of the academic environment. In the Centre region, the Smart specialization Strategy covers the period 2021 – 2027, developed by the Centre Regional Development Agency, in collaboration with strategic regional partners. The strategy includes the measures programmed for building the economic culture of innovation, identifying areas of excellence for the intelligent development of the Central Region. For the South-Muntenia region, the Smart Specialization Strategy for the years 2021-2027, comes with innovative change, for regional economic development, with the strategic approach to development by supporting research and innovation. The vision "South Muntenia Region is the innovation and development of economic competitiveness, the development of the innovative regional ecosystem, the development of green and digital transition skills, towards a circular economy, the improvement of conditions for the support and development of intelligent specialization". The Bucharest - Ilfov region represents a developed labour market, with an activity rate of 91.5%, and is the national average. The region has the highest share of higher education graduates, the highest percentage of the population of working age, with higher education, above the national and European average, and represents the favourable factor of economic development based on knowledge, with the support of intelligent specialization. The Smart Specialization Strategy of region Bucharest-Ilfov in accordance with the classification of the regional innovation scoreboard, the Bucharest-Ilfov region classified as an Emergent Plus+ innovator in 2021. The table evaluates the performance of the level of innovation in European development. In comparison to the other regions of the country, the Bucharest-Ilfov region is the most developed, although the continuous values reduced compared to the level of developed countries in the EU.

2 The evolution of the labour market in the European Union in the period 2012-2021

2.1. The evolution of the labour market in the European Union

The evolution of the labour market in the European Union. Labour markets across Europe are currently facing various systemic crisis problems, the aftermath of the Covid-19 pandemic crisis, and the effects of the regional crisis (Burlacu et al., 2020; Radulescu et al., 2021). The evolution of the number of employees in EU countries was increasing in the period 2012-2021 from 183.244.1 mil employees. The highest number of employees recorded in 2019, reaching 194,892.2 million employees, with a small drop in 2020 to 191,805.7 million employees, caused by pandemic restrictions, and an insignificant return to 192,962.3 million employees in 2021 (Eurostat).

Table 1. Evolution of unemployment rates în EU in period 2012 – 2021 (%)

	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021
EU - 27 / from 2020	10.9	11.4	10.9	10.1	9.1	8.2	7.3	6.7	7.1	7.0

Source*:* Eurostat, Evolution of unemployment rates by sex, age, level of education and NUTS 2 regions (%)

Despite the positive performance of the labour market, the percentage of long-term unemployed among the unemployment population remained high (45.4% in 2012). In this context, the PES provided free and impartial services to reintegrate jobseekers in the labour market and to support a better alignment between labour supply and labour demand. In EU countries, unemployment rates registered a continuous decrease in the period 2012-2021 from 10.9% in 2012, to 7.1 in 2020 and 7.0% in 2021. In the year 2022, it is the forecast of 6.7% and 6, 5 % in 2023. Ukrainian citizens who migrated to the EU due to the war are gradually integrating into EU countries and gradually entering the labour market, the tangible effect will reflected in next year's labour market statistics. In the EU, it estimated to increase the remuneration of employees per capita by 3.9% in 2022, by 3.6% in 2023. As in 2021, the respective growth rates are much higher those recorded in previous years, being below the level of inflation growth.

2.2 The evolution of the Romanian labour market in Romania by macro-regions and development regions
Figure 2. Employment by sex, age, economic activity and NUTS 2 regions 15 - 64 ani

Source: Eurostat, Employment by sex, age, economic activity and NUTS 2 regions (NACE Rev. 2)

In Romania, the unemployment rate reached 5% in September 2021, decreasing by 0.2% compared to the previous month, according to the information of the National Institute of Statistics. [18]. According to the INS, the estimated number of unemployed in September 2021 was 416,000, 12,000 less than in August. For the 25-74 age group, the unemployment rate estimated at 4.1% for September 2021 (4.2% for men and 3.9% for women). The number of unemployed aged 25-74 represents 76.6% of the total number of unemployed, which estimated for September 2021. Unemployment rate for men, from 5.3% (exceeded by 0.6%) compared to the percentage rate for women - 4.7%. The high level of the unemployment rate in the social group of young people (15-24 years old) of 19.5% remains high. By sex, the unemployment rate for women exceeded 0.1%, the rate for men (from 5.8% for women, and 5.7% for men), and the unemployment rate among young people (15-24 years) 22. 0 %. The table below reflects the evolution of the unemployment rate by macro-regions and by development regions of Romania.

Table 2. Evolution of the unemployment rates in period 2012 – 2021

The Bucharest - Ilfov region, with a population of 2,280,797 in 2012, to 2,324,679 in 2020, has the highest share of employment, from 80.3% in 2012 to 89.4% in 2020. In the municipality of Bucharest, the population decreased from 1,881,180 in 2012 to 1,829,443 in 2020, the share of the respective population evolved from 82.3% in 2021 to 97.6% in 2020. In Ilfov county, the population increased from 399,617 in 2012 to 495,236 in 2020, respectively the share of employment, from 69.4% a decrease to 60.3%. In macro-region 4, in 2012 the population registered with a figure of 3,884,824, and in 2020 it decreased to 3,667,196, respectively, in employment 62.2% registered in 2012, and 68, 5% in 2020. The South-West Oltenia region registered a population of 2,058,288 in 2012, and in 2020, a decrease recorded, registering a number of 1,901,748.

2.3 Employment in the field of technology and knowledge

New technological systems have the potential to change the way people work. Disruption is both a new opportunity and a new challenge, given the new opportunities in the field of digital technologies, digital platforms. The education system is not yet facing the radical changes of digitization and implementation of new technologies. In the EU, the number of employees in the field of new technologies has increased from 5,830,000 in 2017 to 7,291,600 in 2021, in Germany from 1,703,700 employees to 2,223,300 employees. In Romania, from 256,800 employees, in 2017, it increased to 263,600 in 2021 (Eurostat).

According to Eurostat information, the number of IT specialists in EU countries increased by 50.5% from 2012 to 2021, almost 8 times more than the 6.3% increase in total employment. In 2021, 80.9% of men employed in Information Technology in EU countries, compared to 19.1% of women. About two thirds of information technology specialists (about 64.5%) in 2021 in EU countries have a tertiary level of education.

Table 4. Employment in technology and knowledge-intensive sectors by NUTS 2

3 Results and discussion - bibliographic study of a new model of the labour market at local level

Consequences of differences in outcomes in different labour markets at the local level. Author (Moretti et al., 2011) examines the causes and consequences of differences in local labour market outcomes and labour markets in a country. The author emphasizes the long-term general equilibrium framework, where workers and firms are free to move to localities, and local prices adjusted to maintain balance. The author has developed a general, adaptable equilibrium framework for local labour markets. *The concept of intelligent specialization*. (Dzemydaitė, 2021) argues: "The concept of smart specialization was implemented in EU countries in 2014, with the statements that regions must specify areas of specialization for the development of innovations". (Muštra et al., 2017) analyse the effects of smart specialization on regional economic resilience in the EU. The term popular economic resilience (RER) is quite popular, it addresses the issue of understanding how regional economies it handles the consequences of high levels of economic dynamism. The smart specialization (SS) approach offers a number of advantages for the appropriate design and development of innovation policies from the perspective of regional policy. The SS approach is compatible with the key features of the regional economy. The resilience and investigation of its effects on the RER offers new perspectives in the RER literature. Authors (Gill et al., 2013), argue, today Europe is a continent with shrinking labour markets. The differences between countries, the existence of a "European model" of work: almost every European economy has stricter labour protection, generous social benefits, in North America, Oceania and East Asia. This has led to low labour force participation, high unemployment, especially among young people, underdeveloped labour markets, and the rapid onset of population aging. The authors are of the opinion: "It is necessary to change employment policies. Europe could lose around one million workers every year for the next five decades, especially after 2030." It is necessary to reform the labour market in close correlation with social protection. Reforming these policies can prevent some of the decline in the European labour force, particularly by increasing the participation rate of older workers and women. The transition from "traditional" regional policies, aimed at bringing about regional convergence, to new approaches, exploiting the economic development potential of regions, is the focus of the authors (Vanthillo et al., 2021), which presents the changing context of regional economic development, the progress of political thinking, the analysis of the respective problems. Special attention paid to regional development strategies in this process, where "regions" can defined more functionally than administratively. Authors (McCann and Ortega-Argilés, 2013) examine the nature, rationale and logic of cohesion policy reforms in the EU. A particular emphasis placed on the concept of smart specialization, on using the concept to facilitate the results-oriented policy agenda. The arguments behind the reforms relate in part to modern thinking about the role of industrial policy. They relate, in part, to advances in understanding the relationships between economic geography, technology and institutions. Authors (Dobrzański and Grabowski, 2019) analyse the structural and productivity changes of the countries of Central and Eastern Europe (CEE), (the research period covers the years following the accession to the European Union, 2004-2018). The respective study aims to answer the question: What are the effects resulting from integration into the European Union in terms of the sphere of productivity? The analysis covers two main categories of labour productivity growth: pure labour productivity growth and structural labour productivity growth. Both structural and pure productivity growth driven by research and development spending, imports of information and communication technology (ICT) goods, and trade openness. The author (Venturini, 2022) describes the fourth industrial revolution (4IR), with an increasing number of studies investigating the effects of the latest

generation of new technologies (artificial intelligence (AI), flexible automation, manufacturing, big data, etc.) defined as smart technologies, considered cutting-edge innovations, with important effects on different dimensions of economic activity. Transformations influenced by new technologies can have revolutionary effects on employment, productivity and other dimensions of the economy. The growing ability of artificial intelligence (AI), robots, etc., to perform tasks with human-like capabilities – especially manual, routine jobs, cognitive tasks in the fields of voice recognition, visual image recognition, translations – explains why the literature specialized focused primarily on the occupational field. Authors (Evangelista et al., 2018), explore the specialization of European Union (EU) regions in key enabling technologies (KETs), assess whether specialization in these technology areas has an effect on regional growth. The evidence presented reflects that the regions specialized in KET are concentrated in central Europe. During the considered period (1996–2011), the less innovative and peripheral EU regions increased their specialization in these technological fields at the expense of the more advanced regions. There is evidence that spatial diffusion of KETs occurs in regions adjacent to each other. The authors (Couture, V., 2015) propose a micro-foundation for spreading knowledge. Modelling within a city, where free knowledge transfers auctioned by experts, to entrepreneurs, who auction jobs. The offers of that knowledge resemble the proposition of consultants to the potential client. Underpinning the model are two fundamental properties of knowledge: First, disclosure of knowledge is necessary to demonstrate its value. Second, knowledge is freely reproducible. Bigger cities generate more meetings between experts and entrepreneurs, resulting in more opportunities for consultation, information, learning and better results. The importance and extent of smart specialization strategies (Lankauskienė et al., 2022) carried out in a short period of cohesion policy in the period 2014-2020, the evaluation of the effect of this complex process on economic development, mobilization through the implementation of intelligent specialization of the regions are still pending. The ecological transformations accelerated by the European Green Deal have highlighted the fact that the strategies for intelligent specialization of the EU regions is to avoid fragmentation, to reach some complementarities in achieving the EU's common ambition - climate neutrality by 2050. The study's authors set out to demonstrate how to identify region-specific pathways for ecological transformation, aligning them with smart specialization strategies focused on the European Green Deal in the regions. The conclusions of the study based on the moderate experience from the two interconnected projects in the area, "LARS" and "GRETA", implemented in the Baltic Sea region (October 2017/September 2021). The research proposes how moderated learning, knowledge transfer between mature innovators and young innovators, embodies place-based path identification, and supports the development of course recommendations for ecological transformation, solving homogeneity issues of smart specialization strategies. Technological diversification, associated with more opportunity discoveries (Aksoy et al., 2022) proximity, diversified technologies in decline is associated with the reduced number of revenue-generating licenses. In the second case, when proximity and high technological diversification are associated with more discoveries and opportunities, with more spreads. In the third case, low technological proximity and high technological diversification are associated with the best performance during the revenue-generating licensing period. The authors claim that: "regional decision-makers, who intend to attract universities as an engine of innovation and regional economic growth, must consider policies and initiatives aimed at reducing the cognitive gap between university and industry, by increasing technological proximities, by reducing cognitive distances, by funding organizations of organizations that cross boundaries."

Research progress in the humanities over the past decade (Feng and Zeng, 2022) has highlighted the robustness of digital methods, ranging from basic data processing

techniques to complex tasks. Some of the humanities disciplines have demonstrated tendencies to depend on digital methods, for examining existing theories/hypotheses, to participate in the development of skills in dealing with practical problems. The authors (Zhao et al., 2022) argue that in the last decade, text-as-data methods have gained popularity among social scientists, digital humanities, business, and governance researchers. The priority objectives, in the fields of digital learning, vocational training and social sciences, directed towards, the use of new tools, educational platforms, software used. To make predictions about the present and future human behaviour in the field of digitization, robotics, which, through interdisciplinary and transdisciplinary approaches, it will contribute substantially to the paradigm changes of the future of social sciences, finding new solutions for social aspects and in the field of the labour market. Authors (Ruffner and Spescha, 2018)**,** combine two rich firm-level data sets to analyse the effect of dense geographic concentration of industries on firm innovation and productivity. The results show that the increased concentration of labour in the same industry is associated with a higher output of innovation, a higher productivity.

The authors (Castellano et al., 2022) state: "Innovation is seen as a crucial factor for regional economic growth. Many branches of literature have investigated the role of the externalities of the agglomeration, of the skills of the workers in the capacity of innovation of the territory without taking into account their interaction. Using Poisson regression, models with fixed effects, on official data for 2014–2019 in the Italian regions, this paper aims to double. (Braunerhjelm et al. 2020) used the unique data set on Sweden, correlated "employer-employee", combined with data on patent applications at company level, and provided new evidence that the mobility of knowledge workers has a positive and significant impact on the company's innovation, measured by companies' patent applications. The effect is statistically and economically significant for knowledge workers who have previously worked in a patent firm, while only a limited impact could detected for companies that lose knowledge workers.

According to the authors (Quintero, S., et al. 2022) the learning approach, understood as the process by which agribusiness creates knowledge and develops capabilities, is the core of understanding the firm's effort to acquire the necessary capabilities to compete in the agricultural innovation system (AIS) to improve the transition to sustainability. Agent-based modelling (ABM) has proven to be a suitable analysis method for the respective phenomena. It made it possible to study the dynamics of local learning, the emergence of specialization models, the improvement of transfer, the adoption of technologies - smart agriculture, increasing productivity, sustainability and reducing the impact on the environment in the agricultural innovation system. According to scientific research, (Zhang et al., 2022) adding value to agricultural commodities helps reduce CO_2 emissions in polluted countries like the United States. Additionally, it was relevant that the amount of CO_2 released per unit of energy spent was positively associated with the amount of energy consumed. Research has shown that adopting renewable energy can help mitigate environmental damage. The smart specialization in the field will support the actions and smart management techniques of technological and operational management. (Ng, M.K. et al., 2022) propose analytical framework to review the critical mode of smart city development to assess sustainability outcomes from a spatial planning perspective. The authors argue that historical context and modes of governance, together with holistic knowledge, provide important clues to understanding the visions, goals, subsequent objectives, processes and content of smart city initiatives. Importance of creative industries (Meyer et al., 2022), studied sustainable tourism which in the South Baltic Sea region is a priority sector, and belongs to the sustainable development model of the Baltic Region (BSR). The paper proposes the reflection of conceptual ways and practices for the political, administrative, corporate, business management of SMEs in the revitalization of sustainable

regional tourism, focused on cultural and creative industries (CCI) that contribute to sustainable development and economic ecosystems. The author (Komninos,2022), focused on research on a green digital transition, the transformations of industrial ecosystems in cities and regions, the identification of ecosystems and ecology based on digital platforms. Opportunities and enabling methods investigated public administrations and SMEs to contribute to the current industrial transformation of cities, regions in full process of digital and ecological transformations and innovations.

3.1 Methodological constructions for the elaboration of a new model of the labour market

Economic specialization reflects the comparative advantage in this field, with arguments linking specialization to economic development. For the formation of smart specialization strategies, the priority issue is to facilitate the success of new future economic activities. Some regions of the EU have applied the LQ index in the context of the analysis of specialization in the formation of the smart specialization strategy. Economic specialization refers to location coefficients, regional concentration of skills and knowledge. It is necessary to investigate the impact of economic specialization on the development of regional and local economies, which offer perspectives for identifying prospective areas in regional economies. The processes of economic specialization, diversification took place in the EU regions, with a different impact on economic growth. The relative specialization index of the location coefficient highlights the degree of economic specialization.

By controlling for region-specific variables, the way in which the complementarity of workforce skills and the productive structure stimulates innovation explored. Second, the investigation of how innovation processes depend on alternative configurations that derive from the interactions between the productive structure and the skills of the workers.

Collaborative innovation in labour market inclusion. This article uses the concept of "collaborative innovation" to discuss the experiences of key stakeholders and service users on innovative labour market inclusion services. *Creative work*. Given the high content of creative work, expertise ensures the competitiveness of companies, acts as a driving force in economic development. Geographical proximity, together with technology, occupies an essential place in the functioning of the local labour market, but for the non-market segment of knowledge flows. *Modelling the optimal search strategies for the unemployed,* models the optimal strategies for finding the unemployed in space to characterize local labour markets. The methodology allows relationships between different areas, while maintaining manoeuvrability. It is, estimated that labour markets are local, and the attractiveness of jobs for applicants suddenly decreases with distance. *Resilience in the local labour market.* The resilience characteristics of local labour markets usually measured in terms of employment growth rates, whether absolute or relative to the EU average. Their skills and typology, participation in the process of generating innovation in the context of MAR specialization, connected skills positively affect the performance of innovation. Guidance provided, to help decision-makers and managers who increasingly need place-based regional approaches to stimulate innovation. The authors found that the local concentration of the creative class has predictive power for the economic development of a region; it tends to go beyond traditional indicators of human capital. The results do not support Florida's claim that creative workers gather where bohemians are.

4 Conclusions

Restructuring of high school and university education systems, adapted to the needs of the market on digital training and technical and technological sciences, mathematics, physics,

and natural sciences. It is necessary to penetrate digitization in other sciences on digital history and archives, digitized geography, digital cultural management, public administration and digitization, sociology and digitization, archaeology and digitization, agricultural and forestry sciences with digitization services. Cooperation with social sciences related to sociology, visual arts, visual arts, have not kept pace with the changing nature of work, which has led to many employers saying they cannot find enough workers with the skills they need. In the vocational schools the penetration of digitalization and programming of computers and robotics in industry, construction, agriculture, transport, and trade. Digital technologies will replace many jobs, but will also create new jobs in industries, services, agriculture, construction, and transportation, in the Smart administration of cities and rural localities. Digital technology will drive sustainable development, support the green economy, and green jobs, support creativity and innovation. From a social point of view, through the easy access of social groups in difficulty, they will be able to support them through access to mobile telephony, access to computers and internet, which will be able to support access to various information related to access to public services, education and culture, medical and social services. For localities in difficulty in areas underdeveloped through digital platforms, it will be possible to ensure access to online platforms for marketing, promotion and sales, information and vocational education, entrepreneurial education that will allow new forms of entrepreneurial activity.

Design and Implementation of an Artificial Intelligence Business Model to Address the Challenges of Global Warming in Agriculture.

Diego Antonio Claramount Ruiz[1,*], and *Stanislava* Simonova[1]

[1] University of Pardubice, Faculty of Economics and Administration, Pardubice, Czech Republic

Abstract

Research background: Given the challenges that global warming is bringing into the agricultural sector especially in developing countries is important to use the tools available in order to provide farmers with more options to find alternatives to the current ways of producing the land while reducing the gap of knowledge and techniques between farmers in the developed and developing world.

Purpose of the article: The current state of the agricultural methods in developing countries is anything but modern, that being said the incorporation of AI for better prediction and account of several factors can provide these farmers with a better solution to improve their conditions and ultimately improve their standards of living.

Methods: Collaboration with local University experts and an international network of collaborators will allow us to collect data from the different areas to construct the different models that can help us all together to provide the best outcome to the final users of our model those being the farmers.

Findings & Value added: The different models of AI models such as Machine Learning unsupervised and supervised ones or Neuronal Networks among others provide a level of analysis of data so far widely spread in the IT industry with applications ranging from translators to Image Analysis. Farmers in developing countries possess a really low level of education that ultimately limits their possibilities to implement such models by themselves, this generates an opportunity not only to improve their standard of living but also the access to modern tools to help them in their daily activities.

Keywords: *artificial intelligence; developing world; global warming; agriculture*

JEL Classification: *Q54; Q200; O350*

1 Introduction

With the now more than ever hard reality of climate change, it has become clear that finding ways how to minimize and perhaps adapt to it is one of, if not the most important task in the coming years. This is unfortunately more time sensitive in developing countries. During the last decades, it has become the norm rather than the exception to have several climate events around the globe. Poor countries are more heavily affected by extreme weather events and future climate changes than rich countries. One of the reasons for this is the so-called adaptation deficit, which limits the ability of poorer countries to adapt and be resilient to these events (Fankhauser and McDermott, 2014).

It is a sad, but the reality is that higher income countries are far better prepared than their less developed counterparts to implement measures to minimize the effect of global warming. If two countries face the same level of hazard one should expect that the one with higher income to spend more in precautionary and hence suffer fewer loses if a natural disaster occurs. (Schumacher and Strobl, 2011).

All these facts combined are causing that the effects in agriculture to worsen by the day, this is clearly explained in Jagermeyr et al. (2021) when the say that potential climate-related impacts on future crop yield are a major societal concern, furthermore that maize productivity could shift from +5% to -6% wheat +9% to +18% potentially linked to stronger CO_2 content in the soil which is directly related to the effect of climate change.

Having outlined that climate change and its effect are affecting in a disproportionate measure developing countries already and even more in the future, the question remains what can we do to help our farmers and be able to bring new technologies to their processes while improving their lifestyle without overexploiting the available resources. After all, farms in developed economies grow until the owner reaches the limit of his or her managerial capacity, which is clearly determined by a combination of personal intelligence, education and tools available to their disposal (Bruntrup and Heidhues, 2002).

To address these challenges, the complex, multivariate and unpredictable agricultural ecosystems need to be better understood by monitoring, measuring and analysing continuously various physical aspects and phenomena. This implies analysis of big agricultural data (Kamilaris, 2017)

Table 1. Areas where small farmers need technical advice, in percent.

	Today	Want More Support
Business Planning and Farm Management	48	31
Agronomy and Livestock	49	62
Processing Technologies	13	7

Source: WORLD BANK SURVEY in Moldova, 2000 (LERMAN 2001)

The table above clearly reflects the idea that Business and Planning is one of the main technical areas in which farmers in developing countries might want and require support in order to improve their overall economic conditions given the specific circumstances that they are facing right now and will most definitely face in the future.

Over the current paper we will present the categorization that can helps us better understand the different factors that are affecting the outputs of the crop yields. Later we will present a few widely known machine learning models and we will be summarizing the models and their effectiveness to better understand which ones can helps us with the categories previously described.

2 Methodological Framework

There have been several studies that focus on developing artificial intelligence models such as fusing different arterial intelligence algorithms and its application on specific areas, such as food security for farm households (Wijk et al., 2014), or on the other hand the economic impact (Ngoune and Shelton, 2020). But so far there hasn't been a multi-model, multi-area approach that would take into account all the factors that can affect farmers. Such a model can potentially become the tool that will bring to the farmers new tools and information to better manage their farms from a business standpoint and that will take in to account potential effect of climate change in their business model.

2.1 Clear definition of the different factors.

There are several factors that play a role in crop and agriculture production. We can categorize these factors into three categories which are technological, biological, and environmental (Ngoune and Shelton, 2020). Different approaches in several countries to minimize the effects of these categories in their crop yield outputs might vary from the increase in land area to the intensification of cropland management techniques such as irrigation, and inorganic fertilizers among others. These 3 factors are the ones that will be analysed and presented in the current paper.

2.1.1 Environmental Factors.

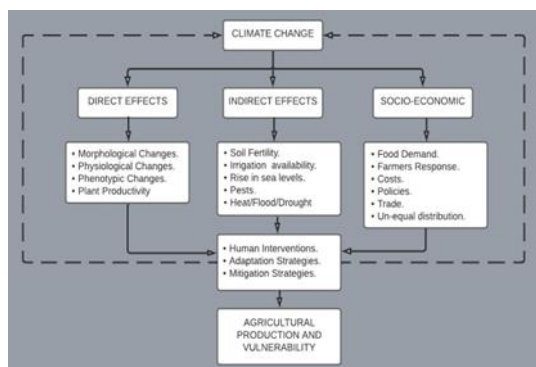
The environmental factors are perhaps the most visible ones since these are directly related with global warming, which leads to climate change Abiotic stresses adversely affect growth and productivity. Whereas the opposite is given by biotic factors. Variations in annual rainfall, average temperature global increase of atmospheric CO_2 and fluctuations in sea levels are some of the major manifestations of climate change, which negatively impact crop yields (Metclfe and Elkings 1980).


Figure 1. General effects in agricultural production.

These factors are also related to abiotic factors. These ones can potentially have devastating effects on plant growth and crop yield which can affect directly, indirectly, and socio-economically speaking reduce crop yields by up to 70%. Weather variations present positive and negative effects in the environment with very high expressions of negative effects (Raza A et al. 2019).

2.1.2 Biotic Factors.

This are living organisms that affect their environments, a good example of this are microorganisms and although this are perhaps not related directly to climate change are indeed affected by it, examples of this are plant diseases which are caused by several micro-organisms, unfortunately, these organisms see their multiplying capabilities enhanced by the variations in climate conditions.

In other words, climate change is affecting the biotic factors affecting the crop yields of our farmers. Furthermore, the change in temperatures is bringing new types of diseases and pests for which we don't have any controls yet, an example of this is maize lethal necrosis (MLN) has become one of the most devastating diseases in Central Africa causing a yield reduction between 30% to 100% (Karanja et al. 2018).
Figure 2. Relations between biotic and abiotic factors.

Source: (Burylo et al. 2007)

2.1.3 Technological Factors.

Over the years there have been a big number of technological factors like genetic improvements, and fertilizer technology just to mention a few. This innovation has caused not only positive changes but also several negative ones, an example is the case in the Philippines where sugarcane fields develop lime year in the subsoil and banana fields have excessive potash which ultimately created an imbalance ratio of potassium and magnesium.

In brief, the application of inappropriate agronomic practices such as untimely planting, incorrect plant spacing, wrong method of planting, poor sowing depth, delayed weeding, ineffective pest and disease control, inappropriate use of fertilizers, untimely harvesting and use of low-yielding varieties, will always significantly reduce crop yields (Ngoune and Shelton 2020).

2.2 Proposed Machine Learning Techniques.

We haves outlined 3 categories that directly affect the overall output of our yields, now we need to define the best approaches that will helps us determine the most adequate model that will fit our needs and provide the best output possible.

2.2.1 Artificial Neural Network.

An Artificial Neural Network (ANN) is a network of artificial neurons. It is based on the human brain's biological processes. The neural network must be trained once, thereafter similar patterns in future data can be predicted, for instance, meaningful problem solutions can be produced even if the input data is incorrect/ incomplete (Mishra et al. 2016).
Figure 3. Yield Prediction Model

Source: Drummond et.al (1995)

2.2.2 Information Fuzzy Network.

An Information fuzzy network (IFN) is a greedy machine learning algorithm for supervised learning. The data structure produced by the learning algorithm is also called Info Fuzzy Network. IFN construction is quite similar to decision trees' construction. However, IFN constructs a directed graph and not a tree.

2.2.3 Decision Tree.

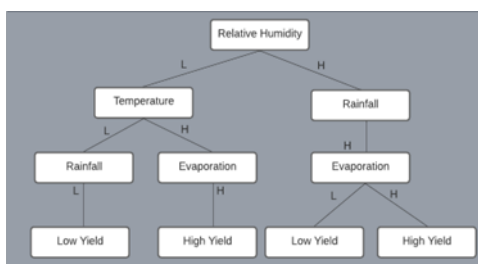
The decision tree goes over a model that includes several different concepts like nodes, branches, terminal values, strategy, payoff distribution, certain equivalents, and the rollback. There are usually three kinds of nodes and two kinds of branches when designing a decision tree.


Figure 4. Decision tree for influence of climatic factors on soybean yield.

Source: Veenadhari et.al (2011)

2.2.4 Clustering.

Cluster analysis or clustering is the process of identifying objects that are similar to each other but different from individuals in other groups. It is mainly used for data analysis. Clustering is used in many fields such as machine learning, pattern recognition, image analysis, information retrieval, agriculture, etc. There are various clustering algorithms are there such as k-means, k-medoid, etc. but the common and important clustering algorithm is k-means. (Mishra et al. 2016).

2.2.5 Bayesian Belief Network.

A Bayesian belief network is a graphical representation of the underlying probabilistic relationships of a complex system. These networks are used for reasoning with uncertainty, such as in decision support systems. This requires probabilistic inference with Bayesian belief networks.

2.2.6 Time Series Analysis.

Time series analysis is the method to analyse time on parametric, series data to extract meaningful statistics and other characteristics of the data. Basically, time series forecasting is a model to predict future values based on previously observed values. There are various types of time series analysis methods such as frequency domain and time domain, parametric or non-parametric, which may be linear or nonlinear, univariate and multivariate. Which one will be the best for your use case will depend on the specifics of your case.

3 Comparison of the different Algorithms - Results

There have been several studies considering one or more of the algorithms that have been described in this paper. In the table below we summarize some of the studies carried out and the conclusions that those studies have drawn on the application of the given algorithm to the study.

Table 2. Summary table of the different algorithms.

Model	Application Area	Studies	Conclusion
Artificial Neuronal Network (ANN)	Corn and Soybean Yield Prediction	Consideration of Rainfall in the yield for corn and soybean. Compared the ANN approach vs the multi-linear regression model (Kaul, et al. 2005).	ANN gives more accurate yields.
	Forecasting Thailand Rice Exports	Forecasting of rice exports in Thailand between ANN, exponential smoothing, and ARIMA models (Co and Boosarawongse 2007).	During the prediction of unseen data, the models performance was poor, as it was able to track the non-linearities the model performance improved.
Information Fuzzy Network (IFN)	Agriculture-based web decision support system	Creating a decision support system for crop selection based on the impact of climate change in Malaysia (Salleh 2012).	Good results were achieved in the recovery of planting material breeders ultimately thanks to good policy decision-making thanks to the support system.
	Crop Selection	Prototype tool to help Canadian farmers for their crop selection (Daryl et al. 2012).	Results were mixed, data contribution was limited, advocating for more prototype tools in order to increase the amount of data points.

Model	Application Area	Studies	Conclusion
Decision Tree	Soybean Productivity Modelling.	Soybean Productivity for Bhopal District (India) (Veenadhari et al. 2011).	Good results determining major influencers on Soybean productivity. Mayor Drawback was identified by only being able to detect low and high predictions of yield but not middle points.
Clustering	Crop Prediction	Comparison of crop prediction K-means algorithm vs modified k-means and K-means ++ (Utkarsha et al. 2014).	Modified K-means achieved the highest number of good-quality clusters.
Bayesian Belief Network	Effects of climate change on potato production.	Assessing the effects that climate change and hence weather conditions had on potato crop production (Yiqun et al. 1994).	Efficiency was higher by using the Bayesian Belief Network.
Time Series Analysis	Impact of Climate Condition on Yield.	Evaluating the Climate conditions effects over the province of Liaonning, China from 1949-2005 (Hong et al. 2012).	The moving average model was regarded as the best option for the forecasting model. And the biggest plus was that it doesn't require a big set of data.

4 Discussion and Conclusion

Implementation of Machine Learning and Artificial Intelligence models in agriculture is still not widespread, hence the level of understanding and applications are still in its early stages.

The extensive review of the different case studies, their results and recommendations it was determined that although there is more than one algorithm that can fulfil our model requirements for a given area and crop in particular, the application of more than one of them will bring more resilience to our model. Now-a-days a growing number of applications of machine learning techniques in agriculture are required for which a large amount of data is currently available from many resources this can facilitate the validation and training of our models in order to validate our research idea.

Moreover, as per the results observed in the studies is clear that there is not such a thing as "one model fits all" approach, hence throughout the course of our research we might find that the chosen path at any given time might need to be revisited and perhaps even re-taught in order to create the best combination of algorithms that will ultimately bring the best result possible.

Building up a suitable model will have certain merits over the traditional forecasting method moreover it is important that for the field to keep growing researchers should share their datasets through different platforms for others to use it for testing, training and validation of their own models.

Abstract

Research background: In recent years, the concept of hazards associated to human-induced, natural, and technological has been the topic of scientific study. This insight occurs at a crucial point in the evolution of humanity when the planet is becoming more reliant and fragile. Numerous hypotheses support the increased chance of causing natural occurrences with significant societal consequences. Experts in insurance and reinsurance see human-caused climate change as the primary cause of imbalance as it becomes more pronounced.
Purpose of the article: The purpose of this presentation is to emphasize the environmental dangers posed by globalization.
Methods: The documentary study corroborated the view of experts who brought attention to the fact that catastrophic natural occurrences may have global, human-wide repercussions and consequences.
Findings & Value added: Globalization expands the reach of multi-risk impacts beyond the borders of countries, so that in many cases impacted they are immediately affected by hazards and disasters. If a calamity strikes a poor country, the international community will react with human and material aid. The detrimental consequences of natural catastrophes in least developed nations are felt more in deep across the global economy, as indicated by significant financial losses.

Keywords: *development; environmental protection; globalization; climate change; hazard*

JEL Classification: *A11; A14; B16*

1 Introduction

According to the processes for evaluating ecological or environmental risk outlined in official documents, this risk refers to the possible effect of human activities on abiotic flora, fauna, and environmental elements (setac.org). When it comes to disaster risk, the United Nations Office for Disaster Risk Reduction associate to this concept 'the potential loss of life, injury, or destroyed or damaged assets which could occur to a system, society or a

---

community in a specific period of time, determined probabilistically as a function of hazard, exposure, vulnerability and capacity' (UNDRR).

In contrast, environmental risk in the business context is defined as the unpredictability or severity of the financial or non-financial consequences of an environmental hazard (Bran, et al., 2018). Therefore, we believe that environmental risks may be described as the effects of natural or anthropogenic hazards that have a negative impact on the environment and ecological systems (plants, animals, crops, settlements, etc.) (Rădulescu et al., 2018). Numerous hypotheses support the increased chance of causing natural occurrences with significant societal consequences (Burlacu & Jiroveanu, 2009). Specialists in insurance and reinsurance are increasingly pointing to human-caused climate change as the primary cause of a disturbance-causing imbalance (Dima, et al, 2020).

In recent years, insurance industry estimates have been verified (Smolka, 2004). The tsunami wave in Southeast Asia, Hurricane Katrina, the earthquake in Kashmir, and, more locally, the extreme floods of 2005 and 2006 are examples of occurrences that support these data. Add famine in Niger, Mali, and Mozambique to the list of natural calamities (Bodislav, et al, 2019).

The tsunami in Southeast Asia, the earthquake in Kashmir, and the floods in Romania exposed the fragility and vulnerability of emerging and transitioning economies, since the number of casualties was astronomically high. In contrast, Hurricane Katrina drew attention to the worldwide economic implications of catastrophic climatic events as well as the larger impact on the underprivileged people. In the not-too-distant future, we may anticipate several catastrophic catastrophes every year with thousands of fatalities and significant property loss.

Thus, in the last period of time climate change effects are having a direct impact on well-being at societal level. The IPCC (2022) acknowledge the need to take urgent actions due to global and regional risks generated by climate change and increased levels of global warming.

2 Methods

The documentary study corroborated the view of experts who brought attention to the fact that catastrophic natural occurrences may have global, human-wide repercussions and consequences.

2.1 Fundamental research

In this context, we investigate the intriguing structural characteristics associated with various types of natural hazards and risks. Regarding earthquakes, therefore, experts concur that the likelihood of human intervention is quite low. The occurrence of volcanism and earthquakes is the result of plate tectonics dynamics, which is formed by processes that occur over millions of years. Till now, there are insufficient data collected to establish even local projections or evaluations of the future development. However, in some cases there are exceptions, especially when the position of the activity of the seismic centre is already known like in the case of Vrancea Region (Romania). The effects of the seismic activity manifested also in the earthquakes in Bucharest area. Based on field observations, researchers believe that here earthquakes occur with remarkable regularity for such occurrences, with a 30-year gap between large earthquakes.

3 Results

When we examine climate threats, the perspective is also changing. Severe occurrences occur with a far greater frequency, and many times due to human-caused activities or due to natural disturbances. Climate data can validate some of these hypotheses.

1. Tropical cyclones are present. Since 1960, the number of tropical cyclones of categories 4 and 5 has increased. This may potentially be the consequence of non-periodic variability, although global climate models clearly show the positive effect of the ocean's consistent warming on this phenomenon.
2. Storms. Rising sea and ocean levels do not pose a threat of flooding. It is not an overnight procedure that happens in silence. Strong storms have a negative impact on the material assets and existence of coastal towns. Experts predict that by the end of the century, incidents with a frequency of 1/60 years will be considered normal, since they will occur every two years (Weather, 2006).

Climate is one of the most variable environmental elements. Although elaborate models were developed, experts were unable to distinguish between anthropogenic and nonperiodic fluctuations. In this aspect, the El Nino phenomena presents a difficulty in being estimated in terms of occurrence being unpredictable. The phenomena happen every three to seven years because to the extreme warming of the Pacific Ocean's waters. It results in harsh weather conditions. El Nino caused record flooding in Chile in 1997, severe drought in Indonesia, heavy rainfall in the United States, a dramatic decline in fish catches in Peru, and spectacular growth in Chile. Over 2,000 people were killed and over 33 billion dollars' worth of property was destroyed as a result of these catastrophes.
Figure 1. Weather disaster losses as % of global GDP (Munich Re) (% of global GDP).

Source: Adaptation according to the data of Pielke (2018).

3.1 Information flow analysis

Analysing the information included in a list created by the U.S. Disaster Centre about the occurrences that have caused the most material damage, we find that floods rank first in

terms of both the magnitude of the damage and the frequency of the danger (the number of events in the top 100 of the hazards).

Enhanced susceptibility. Vulnerability, i.e., the degree of exposure of human lives and material goods to the occurrence that happens, is an additional key factor in resolving the challenges associated with natural disasters, among others. Population expansion and urbanization, particularly the emergence of megacities in recent decades, environmental deterioration and anthropogenic changes are among the characteristics of the globalization period (Burlacu, et al., 2019).

The population is becoming more concentrated in metropolitan areas (Alpopi, et al, 2018). In 2007, for the first time in human history, more people will reside in urban regions than in rural ones (Burlacu, S. et al., 2018). These developments have made populations more vulnerable to natural disasters. The Disaster Centre's rating becomes meaningful from this perspective as well. The pace of rise in the worth of the damages rose dramatically from year to year (Jianu, et al., 2019).

The most 'expensive" incident was the 1995 earthquake in Japan, which caused over $175 billion in material damage. The escalation of risk exposure has insurance firms more anxious. The capacity of these organizations to endure the strain of rising risks and vulnerabilities is shown by a 2000 research. Hurricanes, storms, and earthquakes are ranked according to the insured value of the property (table 1).

Table 1. The costliest natural disasters.

No.	The event	The region	Date	Generated losses (billion dollars)
1.	Hurricane Katrina	US	2005	167,5
2.	Hurricane Harvey	US	2017	130,0
3.	Hurricane Maria	US, Puerto Rico & Rep. Dominican	2017	93,6
4.	Hurricane Sandy	US	2012	73,5
5.	Hurricane Irma	US	2017	52
6.	Hurricane Andrew	US	1992	50
7.	Drought in California	US	1988	44,2
8.	Flooding centre of the US (Midwest)	US	1993	37,7
9.	Hurricane Ike	US / Caribbean	2008	36,3
10	Drought in California	US	2012	33,9

Source: https://www.investopedia.com/financial-edge/0311/the-financial-effects-of-a-natural-disaster.aspx

The escalation of risk exposure has insurance firms more anxious. The capacity of these organizations to endure the strain of rising risks and vulnerabilities is shown by a 2000 research. Hurricanes, storms, and earthquakes are ranked according to the insured value of the property (table 1).

Ioniţă et al. (2009) found that environmental deterioration and anthropogenic changes also increase susceptibility. For instance, agriculture diminishes the soil's absorption capacity, which exacerbates the effects of floods, even if the severity of the meteorological processes remains constant. Destruction of mangrove swamps in Sri Lanka has made coastal towns more susceptible to tsunami surges. Changes in rainfall distribution and infiltration may be caused by deforestation, increasing the catastrophic potential of floods (Burlacu, et al., 2018). There is evidence that environmental changes in the Himalayan Mountain region increased the quantity of debris and catastrophic floods that caused over

$2 million in damage to Bangladesh in 1988, 1991, and 1998. In Cameroon, unstable slopes were constructed on the hills around the towns, resulting in hundreds of casualties from landslides every rainy season. In 1999, because to a lack of urban planning in Venezuela, almost 30,000 people perished in the most advanced towers.

The tsunami that occurred in December 2004 was seen as a warning signal. This catastrophe directly impacted eleven nations and caused damages in more than fifty states, including those incurred by visitors from northern countries. The oil price was impacted by Hurricane Katrina for many months; however, the worldwide financial impact was short-lived.

Scientists call attention to the reality that catastrophic natural occurrences may have global ramifications and repercussions, affecting all of mankind. Extreme events occur with extremely low frequency, and their potential consequences include a global economic crisis, tens of millions of victims, the catastrophic and irreversible destruction of megacities, the endangerment of global food reserves, the disruption of transportation and communication systems, and widespread pollution. In addition, these impacts will result in starvation, diseases, political conflicts, the breakdown of social order and national and international institutions, war, and perhaps the extinction of humankind.

The rising effect of natural disasters must be seen in the perspective of an increasingly complex, interconnected, and vulnerable global community. Changes resulting from human activity and the increased susceptibility of communities are the primary drivers of economic expansion. However, human-induced climate change is considered a potential contributor to the rise in the frequency of severe occurrences (Burlacu, Georgescu et al., 2022).

4 Discussion and Conclusion

In recent years, the hazard of severe hazards and risks occurrences has been the topic of scientific community. This insight occurs at a crucial point in the evolution of humanity, when the planet is becoming more reliant and fragile. Globalization looks to be an irreversible phenomenon, with collaboration, international accords, and the global community gaining popularity (Alpopi, Burcea, et al, 2022). The countries have participated in cooperative efforts to address key issues.

This worldwide endeavour has both good and bad examples. The international cooperation through the Montreal Protocol for the Protection of the Ozone Layer is seen as a success by both the world community and experts. On the other side, the Kyoto Protocol remains contentious.

The foundations of success are scientific certainty, the participation of developed and transitioning nations, and substitutability. The foundations of failure include scientific ambiguity, bigger dimensions, deep economic repercussions, and restricted physical, economic, and political substitutability. Principal obstacles are high prices, the decrease of emissions from big emerging nations (China, India), and adherence to the precautionary principle.

Globalization extends the impacts of chance beyond the boundaries of countries immediately impacted (Rădulescu et al., 2022). If the tragedy happens in underdeveloped nations, the international community reacts with material and human aid as well as solidarity. If catastrophes occur in affluent nations, the negative repercussions are perceived on a global scale, manifesting as significant financial losses.

Globalization process increases the interconnections and risks exposures on communities and societies, regions and countries. In this regard, the degree of adaptation and mitigation processes could address the global challenges and opportunities related to climate change. Therefore, finding suitable solutions to various types of hazards and risks

is important to increase the degree of preparedness through developing collaboration and partnerships at national and international levels.

The reach of multi-risk impacts is extended beyond the borders of countries as a result of globalization. As a result, countries that are impacted are in many cases instantly impacted by hazards and disasters. If a disaster befalls a developing nation, the international community will respond by sending both people and material relief. Significant monetary losses are one indication that the negative effects that natural disasters have on the economies of the world's least developed countries are felt more profoundly across the economy.

Abstract

Research background: The growing environmental problems with a global impact on the quality of the environment require attention from all countries, having international and worldwide dimension, and the urgent adoption and implementation of established measures to protect the environment.

Purpose of the article: The presented contribution points to the necessity of financial resources in the process of improving the environment. It aims to analyse public expenditures and investments spent on the environment in the European Union, compared with the situation in Slovak Republic, as well as to identify the main environmental areas that are supported by investment funds. The aim is also to assess the effectiveness of the funds spent in the relation to the selected indicators, focused on the waste management.

Methods: The main approach to make the determined research is the analysis of the state and the development of public expenditures and investments, as well as the analysis of the ways and approaches, municipality uses for municipal waste management.

Findings & Value added: The contribution results in the finding the trend of the investment to the protection of the living environment in Slovakia that can be used for green economy management. The results can be used for public administration, as well as private investment considering to the living environment.

Keywords: *public expenses; investment to the living environment protection; waste economy; energetic evaluation*

1 Introduction

The pillar of the implementation of Agenda 2030 in the EU is the 8th Environmental Action Program, which is a plan for people, the planet, and prosperity. The pillar stresses the need to improve the implementation of European environmental legislation, increase awareness and communication with the public, ensure the systemic nature of Europe's climate and environmental challenges, (Belanová, 2005) as well as the need to accelerate the transition to a resource-efficient, safe and sustainable economy, production and consumption. Sustainable product policy can make a significant contribution to reducing waste. Where waste generation cannot be avoided, its economic value should be exploited and its impact on the environment should be eliminated or at least minimized (Zaharova, 2019; Mlynárová, 2021).

These facts need to be addressed at a global level, as the amount of waste is constantly increasing, and waste is thus becoming one of the most pressing problems of human existence. This is also indicated in the World Bank's forecast, which estimates that global waste production will increase to 2.58 billion tons by 2030, and 3.40 billion tons by 2050, which presents more than double the growth of the population over the same period. A rapid increase in waste is expected in low-income countries, where the waste will increase more than triple by 2050, mainly in East and South Asia and Sub-Saharan Africa. It should be noted that in these countries, more than half of the waste is currently landfilled and the growth of waste will have huge consequences for the environment, health, and prosperity. Mainly solid waste arising from construction activities is a grave concern in many economies, with heavy regulations by authorities. Vivian and Tam (2013) tried to evaluate new policies based on the latest waste management philosophies available (e.g., the reduction, reuse, and recycle principle, and the polluter pays principle) having an effective impact on the sustainable development of the living environment (see also Mihaliková et al., 2018). Environmental policies are on the agenda of almost all countries of the world, connected with modern innovative technologies, used in the area of waste treatment; however, not all countries and communities give the same priority to environmental policy (Ladaru et al., 2019; Lobova et al., 2022).

In accordance with the Agency 2030 (EEA, 2020 and Envirostrategy, 2019) for sustainable development, Slovakia uses the strategic documents. Slovakia, as well as other member EU states, is trying to maintain and observe long-term competitiveness and to provide sustainable development in accord with all environmental aspects. The European Union is also paying close attention to the issue of waste since from 2012 to 2018; there was a 6.34% increase in waste in the EU. Although municipal waste does not account for a large proportion of waste in many countries, it is the most difficult to manage due to its diversity. The investment to the living environment protection is connected with presently emphasized circular economy, impacted the living environment as well (Busu, 2019 ; Andabaka et al., 2019).

2 Methods

The environment presents a public good that is financed from public budgets. The base of the paper is to evaluate public expenditures and investment to the living environment in Slovak Republic, as well as to identify the main environmental areas, to which the financial sources flow. The main goal is to evaluate effectiveness of the investment in relation to the communal waste.

Therefore, during the research we resulted from the data from Ministry of Environment in the Slovak Republic, where on average, more than two thirds of all expenditures of the Ministry of the Environment and the Environmental Fund come from EU sources, including

co-financing. By environmental protection expenditure, we mean funds for all activities related to the prevention, reduction and elimination of any pollution. The aim of expenditure is to maintain or improve the quality of the environment, or to reduce adverse effects.

We considered environmental costs spent on reducing and eliminating environmental pollution, as well as on prevention itself. These are expenditures arising from air and climate protection, wastewater management, waste management, soil protection and remediation, groundwater and surface water, noise and vibration reduction, biodiversity and landscape protection, radiation protection, research and development (Mihaliková et al., 2018). Their monitoring and analysis is helpful due to the evaluation and monitoring of environmental policy itself and from the point of view of ensuring coordination between the policies of individual member states. In addition to the environmental expenditures of the Ministry of the Environment, the Statistical Office of the Slovak Republic (Statistical Office SR, 2020) also systematically monitors financial indicators of environmental protection for enterprises. The total environmental protection costs and revenues related to the sale of products, devices, components and technologies intended for environmental protection, the sale of by-products or waste products and revenues from the provision of environmental protection services to other entities are evaluated.

The source of the other necessary data for the analysis were data from Eurostat databases, Public Administration Budgets, published by the Ministry of Finance of the Slovak Republic, statistical databases published by the Statistical Office of the Slovak Republic. In the frame of single analysis, we resulted from the continuously published values of chosen indexes from the portal https://ec.europa.eu/eurostat/data/database in available years (Eurostat, 2020). Collected data had been registered, sorted and adjusted in database in MS Excel according to the demand of statistical software JMP, to which adjusted data had been transported and consequently analysed.

3 Results and Discussions

3.1 Investment of the municipalities to the waste economy

From the point of monitoring by the Statistical Office, economic instruments for environmental protection also include investments in environmental protection. Investments for the protection of the environment are considered as investments made for the acquisition of long-term assets used for the protection of the environment (machinery, equipment, land, etc.) in the form of purchase or own creation, including technical improvement. The data of investment are given in the following table 1.

Investments in environmental protection as well as investments in waste management were volatile. The highest investments were in 2012, followed by a significant decline the following year. After 2016, however, it is possible to follow their growing trend again. Overall, it can be stated that the investments of municipalities in the field of waste management have a relatively strong share, from 31% in 2014 to 65.5% in 2016.

Table 1. Investments of the municipalities to the living environment protection, especially to the waste management (thousand Euro)

	2012		2013		2014		2015	
	Value	%	Value	%	Value	%	Value	%
Investment to the living environment	62054		41046		33727		40998	
Investments – waste management	33347	53,7	13752	33,5	10488	31,1	24437	59,6

	2016		2017		2018		2019	
	Value	%	Value	%	Value	%	Value	%
Investment to the living environment	17129		32944,0		58497		52160

Source: own processing according to the data from Ministry of Finance, Slovak republic, Budget of public administration, SR (2012–2019).

3.2 Subsidies to the municipalities from the Environmental fund

Economic instruments are important in the implementation of environmental policy. Through them, negative effects on the environment of individual polluters can be compensated. Economic instruments can be negative (fees, fines) or positive (preferential taxes and levies, loans and subsidies). Among the positive economic instruments to which we will pay more detailed attention are the subsidies provided for environmental protection. They contribute to a positive change in the behaviour of polluters. This type of economic instrument is also indicated in the Database of Economic Instruments used in the implementation of environmental and natural resources management policy, which is maintained by the Organization for Economic Aid and Development and the European Environment Agency (EEA, 2020). At the same time, this is pointed out in the Act, which states that legal or natural persons who protect the environment or use natural resources in accordance with the principles of sustainable development may benefit from adjustments to taxes and levies or the provision of loans and subsidies.

Economic instruments in waste management follow the economic instruments of environmental policy, which use the price mechanism to achieve environmental goals. Their aim is to stimulate waste producers to apply environmentally friendly technologies, more efficiently using production inputs, to support waste recycling and composting (Čulková et al., 2016). Ofuji (2015) states that economic instruments aim at meeting the environmental goal, namely the reduction of waste, as well as the elimination of landfills, which adversely affect natural resources as well as human health. On the one hand, they can

economically burden the environmentally negative activities of the business sphere or, on the contrary, favour their ecological behaviour.

Subsidies are generally non-refundable funds that a grant applicant receives, under defined conditions, mostly for a specific purpose. If they are provided from the state budget of the Slovak Republic, resp. from the funds of the European Communities, it is necessary to understand them as one of the forms of state, resp. European support for identified priorities or development programs. If the state is the provider of the subsidy, the state may specify the specified conditions, or may determine other conditions that will ensure maximum economy and efficiency of the subsidy and is obliged to clearly define the purpose for which the subsidy is provided (Act 523/2004). It should be noted that in the case of drawing public funds, any provision of subsidies is subject to many conditions and criteria in order to maintain the effectiveness, efficiency and economy of expenditure. Subsidies are also used in environmental policy to directly or indirectly limit the use of something that has a demonstrable negative impact on the environment. In waste management, they can be used to promote better waste management, waste reduction and investment in improved waste management. They can take the form of direct subsidies or tax exemptions. Governments often use incentives and subsidies to induce certain behaviours between businesses and households. In particular, subsidies and tax exemptions are often used to support investment in improved waste management infrastructure. Other incentives include, for example, financial payments to municipalities and waste treatment facilities that improve the efficiency of waste treatment, municipalities that agree to a landfill (Israel), payments to companies or households to promote recycling and proper waste management (Environmental Fund, 2022).

The Environmental Fund was established in order to implement state support for environmental care and environmental creation on the principles of sustainable development. The main mission of the fund is to provide funds to applicants in the form of subsidies or loans to support projects aimed at achieving the objectives of state environmental policy. The following table 2 provides an overview of requested and provided subsidies to the Environmental Fund.

The starting point for the provision of support in the form of a subsidy to applicants is the annual publication of the specification of support for activities in the form of a subsidy for which applicants can submit applications. During the analysed period, there were the most applicants in 2017 and in last two years there has been a significant decrease in applicants for subsidies. However, it should be noted that in terms of the number of applicants to whom the subsidy was also provided, the situation has improved significantly over the years. The table 4 shows the annual increase in the number of applicants who received the subsidy, up to 35.95%.

Table 2. Support of waste economy by subsidies in Slovakia

	2012	**2013**	**2014**	**2015**
Number of applicants	299	290	288	227
Applied sum	47 381 246	46 071 650	52 290 815	28 841 277
% from applied subsidies to waste economy from total subsidies	11,65	11,96	10,07	9,303
Number of approved subsidies	1	22	35	32
Provided sum	281 139	2 170 348	2 638 758	2 797 526
% from provided subsidies to waste economy on total subsidies	0,87	10,28	6,91	12,55

	2016	**2017**	**2018**	**2019**
Number of applicants	231	362	120	153
Applied sum	30 466 931	49 804 635	8 437 045	10 630 076
% from applied subsidies to waste economy from total subsidies	10,49	15,265	6,55	9,43
Number of approved subsidies	49	47	37	55
Provided sum	5 512 876	4 262 058	2 570 370	3 279 741
% from provided subsidies to waste economy on total subsidies	14,9	22,338	7,81	8,489

Source: own processing according to Environmental Fund 2022

In terms of the required amount of subsidies, subsidies for the area of waste management were requested on average at the level of 10.58% of the total requested subsidies registered by the Environmental Fund. The highest value was required in 2017, on the contrary the lowest in the following year 2018. The provided subsidies for waste management amounted to approximately the same percentage, on average 10.51% of the total subsidies provided by the environmental fund. The highest value of subsidies was allocated to waste management from the total subsidies in 2017. The following table 3 shows the success of applicants and subsidies received.

Table 3. Success of applied projects (%)

Success	2012	2013	2014	2015	2016	2017	2018	2019
Value	0,59	4,71	5,05	9,7	18,09	8,56	30,47	30,85
Number	0,33	7,59	12,15	14,1	21,21	12,98	30,83	35,95

Source: own processing according to Environmental Fund 2022

The presented results point to an improvement of the situation. Thirty percent of the requested funds were also provided in the last two years, although it should be noted that the value of subsidies decreased compared to 2016 and 2017. Although the situation is improving in terms of the number of applicants and subsidies provided, many applications are still rejected. The reason is often the delivery of incorrect documents or failure to meet the deadline or it happens that the applications do not fall within the submitted call. The application assessment process consists of the first stage of checking the completeness and formal correctness of the applications. Applicants with incomplete or incorrectly completed applications are invited to complete them within the set deadline. Complete applications are submitted for evaluation by fund staff and external evaluators. After evaluation, they are submitted to a meeting of the fund's board, which has a recommendation character for the minister. The Minister decides on the allocation of the subsidy in the form of a written decision on the provision of support in the form of a subsidy. (Environmental Fund, 2012 - 2019). The development of applied and provided subsidies to the area of waste economy from European Fund is given in Figure 2.
Figure 2. Applied and provided subsidies in area of waste economy from the Environmental Fund

Source: own processing according to Environmental Fund 2022

Finally, we compared the situation in Slovakia with EU countries. As we can see in Table 4 the range of the published data for individual indexes are significantly different, while the volume of data connects with data incompleteness in the countries.

Table 4. Structure of data collection in EU

Index	Number of measurements	Analysed period
Investment to the living environment in mil.€	2928	2006 - 2019
National expenses to the living environment protection	3555	2006 - 2020
Environmental donation	77574	2011 -2019
Expenses to the living environment protection per inhabitant	14796	1995 - 2013
Communal waste	21927	1995 - 2020

4 Conclusions

In the content analysis of the paper, we pointed out the importance of investing in environmental protection and one of the environmental problems—the growing amount of waste. We have defined public spending and investment in the environment and pointed to many authors who have researched this aspect in their scientific papers. The main part of the paper was devoted to the analysis of trends and comparison of public expenditures and investments in the EU and Slovakia in individual areas of the environment.

Public spending on the environment presents one of the important economic tools for achieving environmental policy objectives and can positively influence polluters' behaviour.

The presented paper examined public expenditures and investments in environmental protection in the EU and the Slovak Republic and the efficiency of their spending in

relation to waste management. This category of investment was chosen because one of the factors that significantly affect the environment in the Slovak Republic and Slovakia still lags behind the EU average in the evaluation of their indicators is waste. In Slovakia, the amount of municipal waste is growing at a relatively fast pace, and their high landfill rate is a negative phenomenon. The main goal of the formulated measures within the environmental policy is to complete the waste management infrastructure focused on improving the collection and sorting of municipal waste and, subsequently, on their recovery, especially material waste. Funding for the mentioned activities comes mainly from the EU structural funds (90%) and the Environmental Fund (10%) (Bak et al., 2020). However, financing of the living environment protection is not possible only from public sources, but demanding also private partnership (Gao et al., 2022).

The aim of the paper was also to point out the relationship between public expenditure and the rate of recovery of municipal waste. The paper consists of the analysis of the dependence in EU countries, and it confirmed that with the growth of public expenditure on waste management, the rate of recovery of municipal waste also increases. This is a signal of the efficient use of funds to improve waste management indicators. Based on this, we can conclude the need to evaluate the indicators expressing the management of municipal waste with a link to the use of funds spent on improving the waste management system. This will help to assess their effective implementation and the fulfilment of environmental objectives.

Cultural globalization and film policy in small film distribution markets in the Baltic States: towards mission economy approach

Audrius Dabrovolskas[1,*]

[1] Turiba University, Department of Commerce, Graudu iela 68 Riga, Latvia

Abstract

Research background: With the expansion of digital technologies audio-visual content started to be produced in large amounts and distributed on variety of digital platforms. For instance, feature films are distributed on video-on-demand platforms already more than 10 years and this release window became a global channel for media content and brought more competitiveness for cinema theatres. Consequently, media conglomerates put considerable efforts into developing better mechanisms for controlling where, when, and how audio-visual content is circulated. However, media company control crystallizes into a market concentration problem, which is highly noticeable in the film distribution sector across Europe where Hollywood film production dominates in European cinema multiplexes and video-on-demand platforms.
Purpose of the article: The aim of the paper is to question the impact of cultural globalization for the distribution of national film production in Europe and especially for small film distribution markets such as in the Baltic States that are constantly challenged and dominated by Hollywood films and provide new approach and orientation from political economy towards mission economy.
Methods: Methodology is based on critical analysis of statistical data taken from official sources –from Estonian Film Institute, Lithuanian Film Centre and National Film Centre of Latvia.
Findings & Value added: Since national film production and distribution in Europe is heavily influenced by film policy it requires new approach in order to bring innovations in fostering national film production and its distribution through collective process, market shaping, long-term financing and possible partnerships between public and private sectors.

Keywords: *globalization; film policy; film distribution; mission economy; culture*

1 Introduction

Since the film industry is the target of national cultural policies in many countries (Crane, 2014), the dominance of Hollywood film industry in a global film market is considered as an example of cultural globalization. Looking from political economy perspective, cultural globalization is associated with cultural imperialism and it questions how political and economic organisation of media industries affects the production and circulation of meaning and what consequences different ways of financing and organizing cultural production can have for public domain and audiences' access (Golding and Murdock, 2000). Therefore, political economists focus on ownership, finance and support mechanisms, and on how the policies of governments influence and affect media content (Hardy, 2014).

Governments engage in media (film) policy in three main ways – through legislation, regulation and subsidizing. Public support (subsidizing) of the film industry is often defended on the grounds it promotes the national culture and at the same time protects it from dominance of other cultures (McKenzie, 2022). In Europe there is a long tradition of state intervention through all these ways and at the same time the risk of national film production is transferred to the state (Morawetz et al., 2007). On the other hand, film policies started to be reconsidered in terms of globalised cultural economy where small national cinema is constantly challenged by the discourses of transnationalism and regionalism (Hill and Kawashima, 2016).

One of the examples could be Hollywood film production and its influence over European national film production and its distribution. There is an argument if European audiences do exercise free choice in selecting U.S. films over local productions, because Hollywood control film distribution market (Pardo and Tabernero, 2012). Since the traditional major studios are international conglomerates that take advantage of economies of scale and scope and especially in distribution, globalization can be seen as a menace in terms of standardization of cultural products (Chisholm et al., 2015). Particularly Eastern European filmmaking was and still may be in a disadvantaged position in regard to international distribution, because a project may be supported on the production level, but not necessarily on distribution (Iordanova, 2002; McKenzie, 2022).

Since film distribution involves not only the choosing a release date of the film, but also the design and implementation of advertising campaigns (McKenzie, 2012) and marketing (Kerrigan and Ozbilgin, 2004), more and more it is considered as a policy (Harris, 2016). In fact, film distribution is the key zone for profit while in Europe only film policy support for the production is constantly emphasized.

Another important factor and a challenge for film policies is that traditional film value chain is challenged by digital disruption, social digital technology that demonstrates its value as a product, and a service and as a means of distribution (Franklin et al.,2013). The digital market is growing rapidly, but the EU internal market couldn't benefit economically if the single market wouldn't be maintained (Pelkmans, 2016) and this is a difficult problem since European film industries are fragmented due to multiple languages, cultures and traditions and composed of hundreds of small and medium-sized enterprises that can only operate at the national level, and the national markets for most European films are too small to make big-budget productions worthwhile (Richeri, 2016).

If we look at a small media markets, they must deal with the following hardships: (1) the shortage of resources, (2) a small audience and small advertising, (3) dependence and (4) vulnerability. First, small media markets face limitations on the production side, and then there are limits on the sales side, because the production costs are similar in small and in big countries, and the revenues realized from the sales of audio-visual

production and advertising are too small for the development of audio-visual production (Puppis, 2009).

The Baltic States and their media markets are among the small ones and still in the development stage since all Eastern European film industries experienced massive cuts and withdrawal of secure funding early in the 1990s (Iordanova, 1999). Later on when the states became more rich with the development of their economies they could allocate more financial support for national and regional production.

On the other hand, if financial support is allocated only for film production while forgetting film distribution, a significant part of European films might not even be presented to national audiences. Consequently, film policies in the Baltic States have to be reconsidered and updated in accordance with a new initiatives that already matched the 100th anniversary of the Baltic States in 2018 where the focus was put not only on allocating more financial support for national film production, but distribution as well.

This initiative to finance more national film production and distribution could lead to mission economy orientation since political economy even though stresses the state's intentions toward media industries in regard to growth, competition and distribution of its products, but new political economy (Mazzucato, 2021) is suggested, because of new approach to public policy, which influence business (Kattel and Mazzucato, 2018) and also:

- value and the collective process involving business, government and civil society,
- markets and market shaping with co-creating and co-shaping them,
- organizations and organizational change through co-operation,
- finance and long-term financing oriented towards societal goals and dynamic institutions,
- distribution and inclusive growth,
- partnership between business and the state,
- participation and co-creation within creation process, discussions and debates.

For instance, value, markets, long-term financing, partnership between business and the state and participation and co-creation are interconnected processes in public sector that could be aligned to foster new areas of markets and focus more not on facilitating change, but rather on creating change (Mazzucato, 2016). Therefore, there is a need to set a priority and after setting it (a transformative activity), there should be policy instruments to support the exploration of the new areas of opportunities as well as coordination devices to assist the formation of networks and partnerships (Foray, 2018). In regard to film policy not only quantity of investment has to be considered while developing national film production and distribution, but quality in the underlying governance mechanisms as well.

2 Methodology and Methods

2.1 Research aim

The aim of this paper is to question the impact of cultural globalization for the distribution of national film production in small film distribution markets such as in the Baltic States that are constantly challenged and dominated by Hollywood films and provide new approach and orientation from political economy towards mission economy.

2.2 Methodology of the research

The calculations of Lithuanian, Latvian and Estonian film distribution and its support are based on yearly official statistics from Lithuanian Film Centre, National Film Centre of Latvia and Estonian Film Institute and also secondary statistical source.

3 Results and Discussion

At first it is important to notice that all three institutions (Lithuanian Film Centre, National Film Centre of Latvia, Estonian Film Institute) responsible for the formation and implementation of film policy in the Baltic States introduced new strategies and regulations to support distribution of national films in 2017 and 2018 that could be associated with mission-oriented approach. National Film Centre of Latvia established film visual identity, popularization and accessibility strategy called "Latvian films for Latvian Centenary" in 2017. Estonian Film Institute and Lithuanian Film Centre issued conditions and procedures for supporting the distribution of national films in 2018.
Figure 1. Financial support for national film distribution in Lithuania and Latvia 2017-2019 (in Euros)

Source: author's calculations according to Lithuanian Film Centre and National Film Centre of Latvia (2022)

Estonian Film Institute provides information about amount of support for national film distribution only from the year of 2020 where 23000 EUR were allocated (Estonian Film Institute, 2022).

Table 1. Market share by admissions of national films in Lithuania, Latvia and Estonia in 2017-2019

	2017	2018	2019
Lithuania	21,47 %	27,41 %	19,03 %
Latvia	7,84 %	22,06 %	20,16 %
Estonia	8,04 %	17,85 %	23 %

Source: Facts & Figures 2020

While comparing the amount of financial support for national film distribution in Lithuania and Latvia it is possible to identify that at least one national film, which distribution was supported by Lithuanian Film Centre was among top-10 most watched films in cinema theatres that year respectively in 2017, 2018 and 2019 while in Latvia only one film, which distribution was supported by National Film Centre of Latvia reached top-10 position among most watched films in cinema theatres in 2018 (Facts & Figures, 2020).

The market share of national films in cinema theatres in Latvia and Estonia have significantly risen between the year of 2017 and after financial support for distribution was started to be allocated according to new regulations (Table 1). In Lithuanian case the market share of national films was already higher and even decreased in 2019 despite the rising financial support.

4 Conclusions

Hollywood film industry's domination in a sense of film production and distribution is an example of cultural globalization that affect small media and film industries. This dominance is challenging for Eastern European and particularly the Baltic film industries that are still developing their film policies.

The year of 2018 was a breaking point for Lithuanian, Latvian and Estonian film policy development since more financial support was allocated not only for national film production, but distribution as well. National Film Centre of Latvia was the first one to introduce the strategy to promote national films through distribution while Lithuanian Film Centre and Estonian Film Institute issued conditions and procedures for supporting national film distribution. These film policy measures are the examples how public institutions can participate in shaping and co-creating markets and start long-term financing oriented towards societal goals that are also connected to fostering national culture. There is still left space for the value creation as such, partnerships between business and state and participation and discussions in film policy since the growth of financial support for film distribution is only one of the financial instruments that helps to co-create the market and focus more on mission-oriented approach.

Auto-evaluation of English language skills of management students in the context of global education

Lucia Dančišinová[1,*]

[1] University of Presov in Presov, Faculty of Management and Business, Konstantinova 16, 080 01 Presov, Slovakia

Abstract

Research background: At present, work practice increasingly requires competencies or skills that add value to the general education of employees. Global education contributes to the awareness of global themes that affect each individual, develops their critical thinking, and deepens their understanding of areas and topics that affect the whole world. Global education often requires foreign language skills that can be understood as part of intercultural and global competences.
Purpose of the article: The aim of the paper is to present the results of the needs analysis of management students to describe the specifics of foreign language teaching to develop soft skills for practice in a global environment. It illustrates the changing needs of the student population.
Methods: At the end of the winter semester of the academic year 2021/2022, a questionnaire survey was conducted among Master's degree management students aimed at auto-evaluation of their foreign language skills and weaknesses.
Findings & Value added: Master's students assessed their foreign language skills in the middle of the assessment scale, with respondents with poorer English proficiency also identifying a higher number of areas in which they see their weaknesses and slightly accumulating the causes of these shortcomings. The results of the survey illustrate the expectations of management students which can serve as a basis for the LSP course aimed at the development of global and intercultural competences.

Keywords: *global competence; intercultural competence; foreign language skills; auto-evaluation; LSP*

1 Introduction

Academic literature dealing with foreign language communication has increasingly focused on topics such as intercultural competence or intercultural communication, which could be

---

[*] Corresponding author: lucia.dancisinova@unipo.sk

also seen in a rising number of university textbooks devoted to intercultural communication (Jeleňová 2014; Ali Taha 2015; Slivková 2015, 2017; Dančišinová, 2022). Many authors (Průcha, 2010; Wang, 2020; Yurtsever and Özel, 2021; Kalaja and Pitkänen-Huhta, 2020) believe that foreign language knowledge is part of intercultural competence and dedicate their research to the development of models of intercultural competence that would not only focus on becoming an effective speaker but also interpreter (Valencia Álvarez and Michelson, 2022; Pondelíková, 2022). From the overview of current literature on intercultural competence, an obvious tendency to analyse intercultural communication in the environment of international trade can be seen.

The current dynamic nature of society's life and the need for sustainable development also place demands on the way students are taught and prepared for practice. The idea of global education is increasingly used in national and international education programmes, while the beginnings of global education in Slovakia as a response to globalisation processes are associated with non-governmental organizations (Globálnevzdelelávanie.sk, 2019). Although there is not a homogeneous definition of global education, the website Globalnevzdelavanie.sk (2019), created as part of a consortium project of three non-governmental organizations (Človek v ohrození, PDCS, and CEEV Živica) and a representative of the university environment (Faculty of Education, Matej Bel University), defines this educational approach as "cross-cutting discipline covering topics in the field of sustainable development, human rights, ecological, multicultural, global education." The aim of this type of education is to understand the relationships between people from developed and developing countries and to support international cooperation (Globálnevzdelávanie.sk, 2019). Global education highlights the global context in learning.

In the current globalised multicultural Europe, it is impossible to function without adequate intercultural communication competence of citizens (Kostková 2012, p. 9). Lustig and Koester (2010, p. 1-3) add that in the post-millennial world, people have no choice whether or not they want to communicate or cooperate with members of other cultures, but individuals must learn to communicate in the right way and understand the importance that culture plays in communication. Demographic, technological, economic, and political changes create a world dominated by cultural differences in a global environment (Osler, 2020; Thesing, Gerritsen and Van Mulken, 2021; Negedu and Ojomah, 2021).

Monceri (2022) claims that intercultural communication is a discipline within a system of science. Pondelíková (2020, p. 57) describes intercultural competence as the ability of an individual in an intercultural environment to react appropriately and effectively. Many authors (Slušná 2012; Abarca Millán, 2021; Ahmadi Safa and Tofighi, 2022; Roiha and Sommier, 2021; Okken, 2022) claim that there are special methodological procedures in intercultural education that contribute to the development of intercultural competence, and the teaching of foreign languages is its important aspect. The aim of the paper is to present the results of the needs analysis of management students to describe the specifics of foreign language teaching to management students to develop global and intercultural competences and soft skills for practice in a global environment.

2 Methods

At the end of the winter semester of the academic year of 2021/2022, a questionnaire survey aimed at auto-evaluation of foreign language skills was conducted among students of the Master's degree of study at the Faculty of Management and Business of the University of Presov (FMB UP). The respondents were management students in the first and second years of study in full-time and part-time forms of study. The questionnaire was distributed in an electronic form via the MS Teams platform and was accessible to all students who enrolled in the Applied Foreign Language for Managers (English) 1 and 3

courses. 177 students were willing to complete the questionnaire; the distribution was as follows:
- full-time students, 1st year: 79 (45% of the total number of submitted questionnaires);
- part-time students, 1st year: 9 (5%);
- full-time students, 2nd year: 70 (39%);
- part-time students, 2nd year: 19 (11%).

The total number of students asked to complete the questionnaire was 349. There were 367 enrolled students, but 18 part-time students attended courses in the first as well as the second year of study. Applied Foreign Language 1 (English) was enrolled by 134 full-time students and 26 part-time students and Applied Foreign Language 3 (English) was enrolled by 156 full-time students and 51 part-time students. The questionnaire was filled in by 50.7% of the total number of full-time and part-time students enrolled in courses; the distribution was as follows:
- 59% of the first year of full-time study (enrolled in the course);
- 35% of the first year of part-time study;
- 45% of the second year of full-time study;
- 37% of the second year of part-time study.

We consider it a representative sample as each student had equal access to the questionnaire and the reluctance to fill in the questionnaire would also be reflected in the information quality of the answers. However, the information value is higher for the full-time form of study.

3 Analysis of results

In the first entry of the questionnaire, students should evaluate their English language skills on a scale from 1 to 5. The chosen rating scale corresponds to the grading scale used at primary and secondary schools in Slovakia, i.e., grade 1 is the best, and the quality worsens towards grade 5, which is the worst rating. The resulting evaluation was an average grade of 2.47, which corresponds to the average quality of knowledge in the middle of the rating scale. The best grade 1 was marked by 27 students and the worst grade 5 by only one student. Better grades of 1 or 2 were marked by 46% of respondents and worse marks of 4 and 5 were marked by 7% of respondents.
Figure 1. Auto-evaluation of English language skills (%).

Source: own processing

The second entry of the questionnaire focused on the self-assessment of English knowledge in the context of its use when students could agree (yes) or disagree (no) with the statement: I think that my knowledge of English is sufficient for the purpose of its use. The majority of students (77%) agreed with this statement. In relation to the previous entry

of the questionnaire, it can be stated that even if students evaluate their knowledge of English as average, they consider the level of their knowledge to be sufficient in the context of its use. Analysis of the answers to the first two questions revealed that 90% of people who rated their English language skills with 1 or 2 grades (46% of the total number of respondents) agreed with the statement that their knowledge was sufficient for what they were using it for. These were mainly students in the first year of full-time study (48% of students who marked 1 or 2 grade).

The third question of the questionnaire was aimed at finding out the purpose of using the English language, while students could mark more options. The options and the percentage of the total number of respondents were as follows:
− at school: 86%;
− for travel: 65,5%;
− at work: 34.5%;
− social media: 73%;
− playing games: 29%;
− watching movies, series: 79%;
− reading books in English: 21%;
− other: 7%.

Entries 4 and 5 of the questionnaire identified perceived weaknesses and their causes and students could mark more options. In the fourth entry, students were asked to indicate one or more options concerning their weaknesses as far as their English language skills are concerned. The options and their percentages were as follows:
− grammar: 57%;
− vocabulary: 56.5%;
− pronunciation: 37%;
− reading comprehension: 14%;
− conversation: 42% ;
− writing: 13.5%;
− listening comprehension: 22%;
− other: 2.3%.

Students predominantly marked their weaknesses in the area of grammar and vocabulary, slightly less in conversation and pronunciation. These are traditional areas of foreign language teaching.

The identified causes of the lack of knowledge, with the options and their percentage of the total number of respondents, were as follows:
− teacher: 3%;
− lack of motivation to learn: 29%;
− laziness: 43%;
− wrong coursebook: 8.5%;
− few opportunities for improvement: 27%;
− fear of mistakes (ashamed of making a mistake): 51%;
− 'I don't have the cells': 16%;
− it is not necessary for me: 2.3%;
− I don't like the English language: 3.4%;
− other: 7%.

The most common cause of the lack of knowledge regarding the English language was a feeling of shame and fear of mistakes, which gives interesting information to the teacher about the affective motivation of students or their emotional stance towards foreign language learning. Other most identified reasons were also laziness, lack of motivation, and

few opportunities for improvement. These options are mainly related to motivation to learn and are of affective nature.

We were also interested in the correlation between the auto-evaluation of student´s knowledge of the English language (entry no. 1), the identification of weaknesses (no. 4), and their causes (no. 5). We tested the interdependence through a linear sequential correlation (Kendall's sequential correlation coefficient) using the Statgraphics XVIII program.

Table 1. Results of the Kendall correlation coefficient.

		Question 1	Question 4	Question 5
Question 1	rK		0.3828*	0.2553*
	n		(177)	(177)
Question 4	rK	0.3828*		0.4468*
	n	(177)		(177)
Question 5	rK	0.2553*	0.4468*	
	n	(177)	(177)	

* significant at the level of significance $\alpha < 0.01$
Source: own processing

Based on the results of the Kendall correlation coefficient, we can formulate the following conclusions:

1. Respondents with worse auto-evaluation of English knowledge (entry no. 1) see their weaknesses (no. 4) in a larger number of areas; or respondents with better auto-evaluation of the knowledge of English see their weaknesses more specifically, i.e., in a smaller number of areas.

2. With the worsening auto-evaluation of the English knowledge (entry no. 1), respondents slightly cumulate the causes of these weaknesses (entry no. 5), i.e., the worse auto-evaluation of the knowledge does not have only one or two reasons, but there are several identified causes of weaknesses related to the English language knowledge.

3. Causes (entry no. 5) and weaknesses (entry no. 4) related to the lack of knowledge are positively interrelated, i.e., more causes mean more weaknesses.

In the sixth entry, students should express their expectations about the outcomes of learning English in the university course of English. They were given several options concerning the areas on which the teaching should focus, and they could mark more options. The areas were selected regarding the purpose of teaching and the professional focus of the students. The options and the percentages were as follows:

− vocabulary: 52%;
− writing a professional text in English: 23%;
− reading comprehension: 35%;
− speaking fluently: 56.5%;
− specifics of English business communication: 48%;
− searching for information in English for professional purposes: 25.4%;
− writing an abstract (final thesis): 21%;
− reading professional texts in the field of management: 18%;
− other: 1.1%.

According to the respondents, the most common area in which foreign language teaching at universities should focus is teaching students to speak fluently. It's a rather naive expectation. Professional vocabulary and specifics of business communication, as the other most frequently identified areas, are already related to the professional focus of

respondents, and have a rational basis. Approximately one-third of students also gave importance to reading comprehension.

4 Conclusion

In accordance with the requirement to develop intercultural and global competences, the LSP courses at the universities should be designed to meet the requirements of the practice. To design a suitable LSP course, a needs analysis was used to assess the foreign language skills of management students at the FMB UP. The questionnaire was distributed to all groups of Master's students in both years and forms of study. However, the largest group of respondents consisted of full-time students in the first year of study (45%). The resultant assessment of their knowledge of English was a grade of 2.47, with respondents agreeing that this level of knowledge is sufficient for what they use it for. The most common purpose of using a foreign language in this group of respondents was for school, in connection with the mass media, and for travelling. The identified areas of their weaknesses regarding the knowledge of English were grammar, vocabulary, and conversation, and the most common causes of the identified weaknesses were fear of mistakes and shame, laziness, a lack of motivation, and few opportunities for improvement. By correlation analysis of the relationships between the auto-evaluation of English, identification of weaknesses, and their causes, we found out that respondents with worse self-assessment see their weaknesses in a larger number of areas, accumulate the causes of these weaknesses, and more causes mean more weaknesses. Students expect English teaching at the university to expand their vocabulary, improve their ability to have fluent conversations, and develop knowledge of the specifics of English business communication.

Abstract

Research background: There is still much debate about whether or not globalization and economic growth are interrelated, and how governments and industrial societies in advanced economies are affected, with the end result being a connection between globalization and corporate and state welfare in terms of development in the long term. A network economy without hierarchies is defined as globalization, and this leads us to hypothesize that global economic growth would be responsible for deindustrialization, income inequality, or change in the welfare of advanced states as a result of globalization.

Purpose of the article: Our research aims to answer the question of whether worldwide syncope is not the result of globalization, what causes them, and also highlight the main characteristics of sustainable development.

Methods: The main research method is the review of specialized literature in order to understand how globalization has been debated in its causal relationship with economic trends and what conclusions have been reached so far. This was doubled by a documentary analysis to highlight the main characteristics of sustainable development.

Findings & Value added: The findings of our research were that globalization has led to a lack of appreciation for the authentic dimension of human nature by many leaders of highly developed countries. If respect for nature was essential to Eastern philosophy, Western philosophy would only recognize respect for man and his demiurgic characteristics. It would therefore come as no surprise that the West has enjoyed unprecedented freedom to plunder, dominate, and desecrate the natural world. Because of this aggressive and selfish approach to humanity's relationship with the natural environment, another threat to the continued existence of the ecosphere would be the management of the planet. The added value resulting from our research is given by highlighting the characteristics of successful businesses and the impact of these businesses on the sustainable development of society.

1 Introduction

There are a number of studies that test the correlation between globalization and the global economy, but there are also a lot of studies that test the result that was obtained: the effect of globalization on governments and on stratification in advanced economies among industrial societies. This type of research has as its final deliverable the correlation between globalization and corporate and state welfare from the perspective of sustainable development (Bran et al., 2018; Bodislav et al., 2019; Profiroiu et al., 2020; Rădulescu et al., 2020a). The idea that globalization represents the framework of a network economy is one that emerges from the academic definitions of globalization (without hierarchies). As a result of this, we are led to the realization that the expansion of the world economy is to blame for phenomena such as deindustrialization, the widening of income disparities, and the alteration of the standard of living in developed countries.

Bran et al., 2019, acknowledge that globalization is not the root cause of the global syncope that we are currently experiencing. The question that naturally arises next is what is causing these global syncopes. Since the 1980s, the global transformation has been observable, particularly in the United States, where a series of political reforms led to the deregulatory of certain economic activities as well as an attempt to dismantle state welfare in favour of corporate welfare. In the United Kingdom, a series of political reforms led to the deregulatory of certain economic activities and an attempt to dismantle state welfare in favour of corporate welfare. To put it another way, the welfare of corporations has essentially taken the place of the welfare of the state. A hybrid model of transformation through global interconnection was created starting with the first syncopation, which was the crisis of the 1970s. This crisis led to the lobbyist empowerment of Main Street by creating productive but marginally streamlined super conglomerates through corporate mergers, plant and utility company closures, and national and corporate downsizing that pursued globalization (Bodislav et al., 2020). This model was based on the transfer of responsibility for the execution of state financial policy to Main Street and Wall Street. Wall Street was tasked with being responsible for the financial execution of Main Street's operations. Main (with a short-term vision) (with a short-term vision). It was determined that the economy of the United States required a significant amount of upheaval because of the adversarial nature of the relationship that the United States maintains with Japan. This conclusion was reached. The difficulties brought on by competition between states could be reframed as opportunities to quicken the rate at which goods and services are distributed all over the world. When viewed in this light, the concept of global competition that has been brought about as a result of globalization can be considered to be a resultant concept (Sarbu et al., 2021). This is a fact that has led to the pursuit of creating artificial competitive advantages (without any real basis), in order to maintain a visible position on the map of the global economic landscape. You can see that the situation has completely changed from what it was like in the 1970s by looking at the diagram that illustrates the current state of the economy in the United States of America (Bran et al., 2019).

2 Methods

Our research aims to provide an answer to the question of whether or not worldwide syncopes are the result of globalization, as well as to the question of what causes them, and it also aims to highlight the primary characteristics of sustainable development. The primary research method involves conducting a review of specialized literature in order to gain an understanding of how globalization has been debated in regard to its causal relationship with economic trends and the conclusions that have been reached so far. This

was supported by a documentary analysis that aimed to shed light on the most essential aspects of sustainable development.

3 Results

In their study titled "Globalization, Governance, and the Environment in the Next Decade," Bran et al. (2019) propose that globalization has broken up into three distinct processes, which are as follows:

1. The expansion of international trade is the first step in the process that characterizes globalization. As a result of this development, companies are no longer competing with each other within their own national economies (which are closed), but instead with all countries that are able to produce a good that is comparable to the one that is traded by the local company. This alters the global competitive model (at the firm level). Additionally, it is a challenge for businesses that are under the impression that outsourcing production is the one and only way for them to expand their profit margin while simultaneously decreasing their production costs (the transfer of work from the developed area, which includes transaction costs, to the emerging or preemerging area).

2. The second process that defines globalization, which includes the Asian Tigers and the inefficiency costs they cause for the United States of America and other developed countries, is also a problem for these businesses. Even though the global economic crisis has slowed the rapid expansion of the Asian Tigers, these nations have still benefited from approximately twenty years' worth of foreign direct investment (FDI) in the target states that have constructed today's high-performing infrastructure, massive investment in human resources, political stability, and trade linkages;

3. The global financial flow is the final aspect that defines globalization. This aspect includes things such as accumulated external debt, equity in global transactions, and currency exchange risk. All of these factors combine to make the national economic system more susceptible to unpredictability, which is why the nation's central banks need to devise new guidelines for the management of exchange rates and put an end to policies that contribute to the build-up of inflationary pressures (the interest rate is directly proportional to the inflation rate and they attract speculators to the market).

It has been hypothesized that additional factors, such as globalization and the use of computers for economic translation, may have a detrimental effect on countries that are still in the process of developing their economies (Wade, 1990; Shaiken, 1993). This would result in the loss of employment based on real production, as well as the loss of people with low levels of specialization, making it difficult for them to be re-employed and producing "ballast" in the labour market, which would lead to lower wages. The loss of employment based on real production would also result in the loss of people with low levels of specialization. In addition to this, this would result in the reduction of employment opportunities based on actual production (Burlacu et al., 2021; Ladaru et al., 2022; Belostecinic et al., 2022; Rădulescu et al.,2021)

Second, the jobs that are being created as a direct result of the expansion of the global economy call for a higher level of education than the jobs that are traditionally referred to as "blue collar" jobs. "Knowledge workers" is the term that's used to refer to people like these (Reich, 1992 apud Bran et al., 2019). The fact that these workers have achieved a higher level of education makes them eligible for a position that pays more, which, in turn, increases the amount of work that they produce (Fligstein, 1999 apud Bran et al., 2019). Both of these factors, in their own unique way, are detrimental to the state of the economy. Because investments in human capital have an inverse relationship to the distribution of skills, individuals who possess fundamental capabilities that are not currently in high demand are still located at the bottom of the distribution (Bran et al., 2020). This leads to an

unequal distribution of income and forces the government to spend money on people who are considered to be "outside the game," also known as misfits. In other words, it forces the government to spend money on people who don't fit in.

As a consequence of this, two aspects of globalization emerge that deceive governments into falling victim to their traps (Burlacu et al., 2020). As a result of widespread layoffs (which have a multiplicative effect because we need to include the families of those who are fired in the discussion of the problem), as well as an increase in requests for assistance from families with low incomes, the need for state protection is growing. In order to provide assistance to these groups, the government implements what are known as "expansive fiscal policies," which ultimately leads to the emergence of new challenges. Governments have difficulty raising taxes and are unable to benefit from these increases because of the theory of optimal taxation, also known as Laffer's curve, as well as the fact that corporations will move their headquarters from a tax execution location to an offshore location if given the opportunity. This is going to happen as a result of companies moving their headquarters out of areas where taxes are being executed and into offshore locations. The process of deindustrialization is ultimately sped up by the fact that globalization makes it harder for individuals to start new businesses (Popescu et al. 2021). Large budget deficits are therefore the result of social pressure and the inability to implement economic policies, both of which cause the value of the national currency to decrease as the deficits get larger. Because of this, interest rates on foreign markets will rise, making it more difficult and expensive to finance the government's deficit spending (Burlacu et al., 2019). When interest rates are high, there is a corresponding slowdown in the economy (Negescu Oancea et al., 2020).

The governments of the world are caught in the web of globalization, which both causes and forces deindustrialization on the national level and exacerbates social inequality. Globalization also leads to and compels deindustrialization on the international level (Rădulescu et al., 2020a). The only way out of this predicament is for the national economy to become more attractive to international investments (globalization is a two-way street). This can be accomplished by having a fiscal policy that is constrained, having a legal framework that is efficient and respected, having clearly defined property rights, and having optimal monetary policy. This is the only way to extricate yourself from this sticky situation (optimal in the sense of maintaining low inflation). The only thing that the government can do to stimulate economic growth and bring in foreign investment is to maintain its level of financial investment in the country's educational system. This is the only option available to them (Angheluta et al., 2021; Burlacu et al., 2021).

The widespread effects that globalization has on an economy have led to the emergence of a new type of capitalism, one in which social inequality is growing, governments are powerless to do anything to fix the problems caused by globalization (due to the fact that State Unions limit the number of things that can be done to maintain a steady rate of economic growth), and the pressure of meritocracy will be the defining characteristic of globalized capitalism in the coming years. However, in order to make sense of the changes and problems that globalization brings, the emerging or soon-to-emerge area needs an argumentative norm.

There are two normative issues that could be brought up: first, the globalization's resistance to openness can be explained by pro-social economic policies that are meant to protect the internal market; and second, there is the potential for a normative gap. Both of these normative issues have the potential to be problematic (the labour market, in particular). However, free trade is the engine of economic growth for national companies (as long as there are competitive trade relationships, the companies will benefit) and the wealth of nations. There is no empirical evidence to suggest that eliminating the social safety net will lead to systemic social insecurity (the creation of a sense of social fear, the

fear that tomorrow's existence will be limited), which will slow down economic growth. This is due to the fact that the free trade system guarantees that companies will engage in competitive trade relationships with one another.

4 Discussion and Conclusion

A prosperous enterprise is one that is built to last by producing goods and services that are competitive in the market, attend to the requirements and pursuits of customers, and generate profits for the enterprise. To have a competitive advantage, a company needs to increase the number of customers it has and improve the quality of the goods and services it offers. All of this is predicated on the fact that the production process generates more value than the capital components it employs (Porter, 1990).

Because in business, decisions are followed by actions and the result is either a successful or an unsuccessful one, the environment of business is very different from the academic environment the political environment, and the bureaucratic environment. To get the most out of your efforts to be successful, you should take the risk of failing about the same on both sides. However, the success that the company has achieved is a contributor to global economic risk, which is developed as a result of the accumulation of all potential scenarios involving gains and losses. If you want to be a cog in the machine that drives the global economy, you have to base your choices on how morally sound they are. If you do not, you might find yourself in a situation where the immoral economic agent is removed from the market in the long run. This is the worst-case scenario. This is due to the fact that the modern economy is structured like a network, which demonstrates how interconnected various economic agents are (either individuals or corporations).

Quantum physics lends credence to the theory that the realities of different subatomic particles are distinct from one another; however, each subatomic particle also possesses its own interactions, which are derived from the potential properties of the particles and not from the particles themselves. Whether or not they can be seen, the world and all of its components are composed of the substance and energy that make up the universe. A holistic understanding of the world is necessary to have complete sensory perception. The stuff that makes up the world is called matter, but it can also take the form of energy (Wheatley, 1999).

The animal spirit is what drives passions and interests, and they have a significant advantage over moral values in that our brains contain more reward receptors for passions and interests than they do for moral values. A culture that prioritizes "self-interest considered from the perspective of the whole" over decisions made by individuals or groups has been shown to be fostered by globalization (Akerlof & Schiller, 2010).

The culture of globalization, which encourages gluttony, was the driving force behind the rise of a consumer-driven economy (Bell, 1978). Due to their greed, they had a desire to "possess," rather than "create." Outside the middle class, "adolescence" can be understood to represent globalization. This is a phenomenon that has emerged in the modern era. On the other hand, the modern definition of "adolescence" promotes apathy, unrestrained consumption, and a lack of responsibility, all of which contribute to the deterioration of the situation over time (Young, 2009).

"Adolescent" globalization was led by Americans, particularly baby boomers, who succumbed to the greed of those who took advantage of the lack of information to do bad things. This occurred because there was a lack of information at the time (Enron and WorldCom). At the beginning of the third millennium, individuals are characterized by their desire to possess things, and moral values are made to serve the "golden calf" of unrestrained consumption.

According to the findings of our study, globalization has resulted in many leaders of highly developed countries having a diminished appreciation for the genuine aspects of human nature. If reverence for the natural world were central to Eastern philosophical thought, then respect for man and his demiurgical qualities would be the sole focus of Western philosophical thought. As a result, it should not come as a surprise that the Western world has enjoyed a level of freedom that has never been seen before, allowing them to pillage, dominate, and desecrate the natural world. The management of the planet presents yet another danger to the ecosphere's ability to continue existing as it has done so for as long as it has because of humanity's aggressive and self-centred approach to its relationship with the natural environment. The contribution that our research makes to society in terms of added value comes from the fact that it sheds light on the qualities that define successful businesses and the influence that these businesses have on the long-term growth of society. These companies would be sustainable because they would produce competitive goods and services that meet the requirements and interests of their clientele while also achieving economic success. In this day and age of globalization, it is essential to take into consideration the importance of striking a balance between the socioeconomic requirements of humanity, the natural and financial resources of the earth, and the preservation of the planet as a whole to achieve sustainable development.

International Business of Railway Undertakings on the single European Railway Market and its Current Form

Igor Domeny[1,*], and *Anna* Dolinayova[1]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: Introduction of the law related to the creation of the single European railway area has brought with it a deregulation of the market for entities based in a Member State, meeting the criteria set for the business in railway transport. With the gradual opening of the market, the number of railway undertakings providing their services abroad has been increasing. It concerns both the state and private railway operators, in the segment of open access services, and in recent years increasingly also in the field of public services subsidized by the public authority.

Purpose of the article: In this article we focused on the share of international business in railway transport services in some selected EU countries. The main aim is to determine the strengths and weaknesses of the current single European railway area from the perspective of degree of market opening for foreign entities and transparent conditions of access to the railway infrastructure.

Methods: To achieve the purpose of the paper, authors used the simple multi-criterial analysis for evaluating the level of international business of railway undertakings in chosen EU countries.

Findings & Value added: Based on the final score from multicriteria analysis it is possible to consider the impact of the individual market indicators on the overall result in the analysis. The resulting market rate is depended mainly on the market deregulation level and market share of foreign railway undertakings on the performance indicators. On the other side, the model of vertical structure is the least influencing factor. The boom of this type of business can come especially with the gradual introduction of public tenders for provision of PSO.

Keywords: *international business; passenger railway transport; railway market deregulation; market share*

JEL Classification: *F23; R40; K23*

1 Introduction

International business of enterprises is in the current global market more and more popular in the field of the transport as well. Establishment of the single European railway area through the railway reforms has led to the deregulation of the railway market in Member States, firstly in the segment of commercial, usually long-distance, and high-speed services. Uniform conditions for licensing the railway undertakings in EU made it easier for foreign entities to enter the domestic market as well. There are still several barriers concerning the different models of structural reforms in individual Member States and regulatory issues in the process of the railway network capacity allocation. Entry of new entities to the segment of international passenger railway transport services can help fulfil the aims of the EU related to the sustainable mobility and quality improvement of the railway transport services. It also helps to create a healthy competitive environment on the market, which increases the efficiency of public transport and will bring benefits to end customers – passengers.

In this paper we have mapped the international business of railway undertakings on the single European railway market. The main aim is to determine the strengths and weaknesses of the current single European railway area from the perspective of degree of market opening for foreign entities and transparent conditions of access to the railway infrastructure. This is performed by using the multicriterial weight method for evaluating these several factors in chosen Member States.

Several authors addressed in their studies the topic of railway market deregulation and access conditions to the railway infrastructure for railway undertakings. Solina & Abramović (2022) evaluate the effects of railway market liberalisation from the EU perspective. Guillen (2022) dealt with a similar topic with focus on new challanges for future public service contracts. His paper analysed the new legal challenges that public service contracts will encounter and what their impact will be on the process of liberalisation or the EU passenger rail market. Alexandersson and Rigas described the process of railway reforms in Sweden from vertical separation to the entry of the first railway companies into the market in open access (Alexandersson & Rigas, 2013). Virgen focused specifically on the entry of new RU´s into the market in open access and the impact of open competition on price developments (Virgen, 2017). A similar study was carried out in Central European countries (Czech Republic, Slovakia, and Austria) by Tomeš and Jandová, taking into account changes in prices and revenues of railway undertakings and also the range of services operated by individual RU´s (Tomeš & Jandová, 2018). Zou et al. (2021) dealt with the issue of market access to the high-speed railways and the economic growth main Chinese prefecture-level cities. Thompson (2021) made a handbook on railway regulation in terms of concepts and market practice. Knorr & Eisenkopf (2022) introduced an alternative regulatory approch for long-distance passenger rail services on the example of Germany. Railways regulation model applied in the United States was adressed by Russell (2020). Jecny & Kaderabkova (2022) wrote about the role of state in railway operation in interaction with development of economic in the Czech Republic.

Topic of international business of railway undertakings brought Altieri et al. (2022) when determining differences in railway strategies on the empirical case of private, public-owned and third-sector railways in Japan. Jiang et al. (2022) dealt with the role of boundary-spanning commitment in international joint ventures companies. The complexity of international business in general has been addressed by Casson and Li (2022) in their paper. Bauer and Friesl (2022) evaluated the synergy effects in mergers and acquisitions. Ma et al. (2022) focused on newcomers in the international business, in terms of the issue of old capital.

2 Theoretical backgrounds

In the field of international business in railway passenger transport we divide between various forms of businesses of railway undertakings. In most cases, they establish their branch in a foreign country in the form of a subsidiary and provide passenger transport services on their own licence and security certificate issued by the regulation authority of the country. Otherwise, there are another business models used, based on the nature of the services and companies participating in their operation. In Table 1 we summarize individual forms of international business in railway transport known in European Union member states.

Table 1. Different international business models of passenger transport in EU

Model	Characteristic	Example of RU/country
direct participation	foreign RU operate services through the parent company abroad	*Regio Jet* – Czech private RU operating open access services in Slovakia, Austria and Hungary *Trenitalia* – Italian incumbent operating open access services in France *NS International* – RU with seat in the Netherlands operating international services to Germany, Belgium, UK, France
subsidiary	establishment of the local branch abroad	*Arriva* – German RU with own subsidiaries in the whole Europe (Arriva trains, Arriva mobility solution…) *Flix train* – German private RU with the subsidiary established in Sweden (Hector Rail) *SNCF* – French incumbent with subsidiary operating high-speed trains in Spain (Ouigo Espana)
joint venture	cooperation of two and more RU by establishment of company with a partial share	*Eurostar, Thalys* – high-speed branch with the share of national incumbents in Belgium, France, and the Netherlands *Trenord* – Lombardian (Italy) railway company cooperate on international services with incumbents in Germany and Austria (DB, OeBB)
franchising	provision of the railway infrastructure and vehicles to the RU under the local brand	model extended in the UK

Source: authors

International business is extended mainly in the segment of open access services, with the participation of both incumbent and private RU´s. In recent years, they also started penetrating to the market with PSO, generally using the model of subsidiary, which is the most appropriate model due to the necessity of the accounting separation of operated services for the purposes of expense reporting and compensation payment. Joint venture business model is usually used when two or more companies operate international trains in open access regime, or they are trying to enter as a competitor with new brand into foreign market.

3 Methods

For the evaluation of the level of railway market opening for foreign railway undertakings in individual states, the method of multi-criteria analysis will be used. The main role of the techniques of multi-criteria analysis is to deal with the difficulties that human decision-makers have been shown to have in handling large amounts of complex information in a consistent way. MCA techniques can be used to identify a single most preferred option, to rank options, to short-list a limited number of options for subsequent detailed appraisal, or simply to distinguish acceptable from unacceptable possibilities (Multi-Criteria Analysis: A Manual, 2009). For applying the MDCA, these steps are necessary in the order:

−   establish the decision context,
−   identification of the options,
−   identification of objectives and criteria,
−   scoring,
−   weighting,
−   examination of results,
−   analysis of sensitivity (Iuga et al., 2018).

3.1 Criteria determination

Criteria for the evaluation have been chosen according to the current requirements on the market with passenger rail transport services in the context of its deregulation and transparent competitive environment on the market. We also divide between two basic types of providing services by foreign railway undertakings (RU´s), which are open access on the commercial basis and participation on the public tenders for provision of PSO. For both modes we determine these evaluation criteria:

−   market share of foreign RU´s on the total operational performance in train-km,
−   market share of foreign RU´s on the total transport performance in passenger-km,
−   number of foreign RU´s acting on the domestic market,
−   vertical structure of RU´s in the country – separated or integrated model (binomial),
−   degree of market deregulation in country – expressed by the liberalization index (LIB index).

3.2 Weighting and scoring

Determination of weights for individual criterion is an issue, considering that a higher degree of subjectivity is present. For this reason, we choose the method of pairwise comparison of criteria to calculate the appropriate weight (Tab. 2). It means that when comparing two criteria, the more significant criterion is rated "1", less important criterion "0". Final weight is calculated as a proportion of the row sum of the criterion and the sum

of all row scores. Formula (1) below is used for the calculation of weight of each criterion w_j, where n represents the number of criteria and f_j a row sum of the criterion possibilities (Multi-Criteria Analysis: A Manual, 2009).

$$w_j = \frac{f_j}{\dfrac{n(n-1)}{2}} \quad , j = 1, 2, \ldots, n$$

(1)

Table 2. Set of weights of criteria using the pairwise comparison.

	market share - tkm	market share - pkm	number of RU´s	verctical structure	market deregulation degree	sum	weight
market share - tkm	-	0	1	1	0	2	0,2
market share - pkm	1	-	1	1	0	3	0,3
number of RU´s	0	0	-	1	0	1	0,1
verctical structure	0	0	0	-	1	1	0,1
market deregulation degree	1	1	1	0	-	3	0,3
					sum	10	1,0

Source: authors

In the case of non-binomial criteria, the score for each criterion is assigned based on the objective expression of given quantity obtained from the available data and statistic databases. Binomial criteria are expressed by values of 0 and 1, whereas 0 is in general assigned to the lower/weaker level of the criterion. For example, the criterion of vertical structure of RU´s assigns a value of zero in case of integrated model and a value of one for the separated model (because of the lower transparency of capacity allocation when the infrastructure manager and carrier are a part of the same holding company).

Table 3. Set of criteria for multicriterial evaluation.

	character	weight	variable	score scale (0-5)
market share - tkm	numeric	0.2	percentual share expressed as a decimal number	0, (0;0.1>,(0.1;0.2>,(0.2;0.3>,(0.3;0.4>
market share - pkm	numeric	0.3	percentual share expressed as a decimal number	0, (0;0.1>,(0.1;0.2>,(0.2;0.3>,(0.3;0.4>
number of RU´s	numeric	0.1	number of foreign railway undertakings with trains in operation	0, (0;1>, (1;3>, (3;5>,(5;n)
vertical structure	binomial	0.1	0/1 - integrated model/separated model	2.5 for "0"; 5 for "1"
market deregulation degree	numeric	0.3	lib index	(400;500>,(500;600>,(600;700>,(700;800>,(800;900>

Source: authors

Set of the criteria for further evaluation is presented in Table 3. For each of them we can see the character of the variable, value of the weight according to the calculation (1) and score scale, when based on the intervals of variable the final score will be assigned. The final score is calculated as a weighted sum of scores assigned to each criterion.

4 Results

For purposes of this analysis, we have chosen several EU Member State with various conditions of the access to the railway market. Some of them are the example of fully legally opened market (Sweden, Germany), in other cases is the process of liberalization of

railway market in country still not finished at the required level (Hungary). Overview of the market conditions in individual countries based on our criteria from chapter 3 is presented in Table 4 (all data are belonged to the year 2020). The market share of foreign railway undertakings expressed in train-kilometres and passenger-kilometres usually does not exceed the share of 10 % with a few exceptions as Sweden wit 34 % market share or Germany and The Netherlands with approx. 15 % market share. While in Sweden we can see international business mostly in open access segment, in other cases are foreign RU´s interested into PSO services which are in Germany and The Netherlands assigned using public tenders. 5 % share of foreign carriers in Slovakia is represented by Czech railway undertakings Regio Jet and Leo Express, which are providing their international trains between Czech Republic and Slovakia as open access services. In Hungary or Spain, there were not any international business provided by foreign railway undertakings, caused primarily by difficult access to infrastructure (which is also reflected in the value of their liberalization index)

Table 4. Overview of market conditions in chosen Member States based on our criteria

	market share - tkm	market share - pkm	number of foreign RU´s	vertical structure	lib index
Austria	< 1 %	< 1 %	1	integrated	784
Czech republic	< 1 %	<1 %	1	separated	726
France	< 1 %	<1 %	1	integrated	602
Germany	14%	9%	>5	integrated	819
Hungary	0%	0%	0	integrated	616
Italy	<1%	<1%	1	integrated	722
Poland	<1%	<1%	1	integrated	720
Slovakia	5%	7%	2	separated	708
Spain	0%	0%	0	separated	554
Sweden	34%	34%	2	separated	850
The Netherlands	16%	5%	2	separated	799

Source: authors by IRG-Rail (2022), IRG-Rail (2021), Rail Liberalisation Index 2011 (2012)

Final score for each country calculated according to the used methodology and scores for individual criteria are listed in Table 5 below. As we can see, the highest score reaches Sweden, followed by Germany and The Netherlands. We can find most of countries in the score interval between 2 and 3. The lowest values belong to Spain and Hungary.

Table 5. Results of multi-criteria analysis

	market share - tkm	market share - pkm	number of foreign RU´s	vertical structure	lib index	total score	order
weight	*0.2*	*0.3*	*0.1*	*0.1*	*0.3*	-	-

5 Discussion

From the results of the multi-criteria analysis an order of evaluated countries based on their total score was achieved. Based on this score and the score of individual criteria it is possible to consider the impact of the individual market indicators on the overall result in this analysis and discuss the international business of railway undertakings in context of market conditions and the access to railway infrastructure in individual Member States.

A combination of vertical separated model with high level of market deregulation usually led to higher number of carriers entering the passenger railway market, while part of them is also in one of the forms of international business. We can see this fact from the final score of Sweden which belongs to one of the most opened markets in the EU. Despite of this, in case of vertical integrated model in Germany we also record a high market rate. We can attribute this to the fact that all long-distance services in Germany are operated in open access mode and therefore international services are in most cases provided by foreign incumbents. On the example of Hungary and Spain as the lowest rated countries based on our results, it is possible to conclude that insufficient market access conditions do not create a suitable environment for international business of railway undertakings in any known form.

In this paper, we firstly made an overview of current forms of international business of railway undertakings in the EU. Using the multi-criterial evaluation, we demonstrate the various levels of market access conditions and the current situation with international business on a sample of selected Member States. From all criteria, we can consider the vertical structure model as the least significant factor involved in the resulting score. The resulting market rate is depended mainly on the market deregulation level and market share of foreign railway undertakings on the performance indicators (train-km or passenger-km). There is still a space for the development of the international business segment, which, however, has been increasing in recent years along with the continuous opening of the market. The boom of this type of business can come especially with the gradual introduction of public tenders for provision of PSO.

For the further research, a comprehensive evaluation of the market conditions for international business in all Member States will be required, which also brings the requirement for a sufficient amount of quantitatively expressible data and use of more accurate methods for the evaluation. The relatively short duration of the deregulation process in the EU on a practical level is also an issue we will have to deal with.

Comparative analysis of labour productivity in agriculture in 8 ex-communist countries in Europe

Victor-Marian Dumitrache[1,*], *Florin* Dobre[1], *Ciprian* Rotaru[1], and *Alexandra Maria* Sarbu[1]

[1] Bucharest University of Economic Studies, Piata Romana 6, 010374, Bucharest, Romania

Abstract

Research background: Across the European Union, the variations the in agricultural labour productivity are significant among countries. The large disparities in agricultural productivity levels between European countries and regions have been a challenge for the CAP since its inception. Despite the EU funding and the market opportunities, the EU countries that were communist before 1989 have a low labour productivity in agriculture, all of them being under the EU average of 19.900 EUR / full time equivalent. These differences may have been generated by the technological capital used across the Eu in agriculture, by the dynamics in the use of land and the share of share of the labour force employed in agriculture at national level.

Purpose of the article: The purpose of these article is to compare the labour productivity among 8 EU ex-communist countries: Bulgaria, Croatia, Czech Republic, Hungary, Romania, Poland, Slovakia, and Slovenia - in the context of globalization – pointing out the socio-economic circumstances that determined the differences.

Methods: We did a comparative analysis of the indicators provided by The World Bank and the Eurostat, that may have impacted the labour productivity in agriculture.

Findings & Value added: The paper may bring insights related to the major differences among these 8 EU ex-communist countries in terms of labour productivity in agriculture, that may be used in improving the EU and the national policies impacting agriculture.

Keywords: agriculture; *labour productivity; land use; ex-communist countries in the EU; farm machinery*

JEL Classification: *O13; J43; P52, E24*

1 Introduction

The main land user in the European Union is agriculture (Profiroiu et al., 2020; Rădulescu et al., 2022). It occupies 174.6 million hectares, or 40% of the total land area (Eurostat, 2017a). The number of agricultural holdings has been steadily declining for several

---

decades, but the size of the farms shows a trend toward greater holdings. In the EU-27, the typical farm size rose from 11.5 ha in 2003 to 16.2 ha in 2013. (Eurostat, 2017a)

As a result of the privatization and redistribution of agricultural land, eastern European countries show the highest rates of loss in the number of farm holdings (e.g., Slovakia: 65.8 percent) (Eurostat, 2017a). Between 2003 and 2013, the EU-27's total agricultural labour force, measured in annual work units (AWU), which accounts for part-time and seasonal employment, declined by 34% (Eurostat 2017a; 2018); the average AWU per farm holding fell from 0.91 in 2003 to 0.88 in 2013. (Eurostat 2017a, 2018). However, the productiveness of the remaining agricultural employment has grown: the average EU standard output (SO) created per yearly work unit, which may be used as a proxy for agricultural labour productivity, grew from 24,101 Euro in 2007 to 34,830 Euro in 2013 (at current prices) (Eurostat, 2017a). The three countries with the largest improvements in agricultural labour productivity between 2007 and 2013 were Slovakia (158%), Bulgaria (123%), and Latvia (112%) (Eurostat, 2017a).

Europe-wide variations in agricultural labour productivity are significant (Ladaru et al., 2022; Popescu et al., 2022). The continental northern-central countries and the continental peripheries, including the Mediterranean, Eastern Europe, and Scandinavia, are shown to have important disparities (Radulescu et al., 2021). For instance, Denmark, Belgium, and Luxembourg have the greatest standard production per annual work unit (155,717 Euro/AWU from 2007 to 2013), while Romania (5958 Euro/AWU) and Bulgaria (6704 Euro/AWU) have the lowest (Eurostat, 2017a). A barrier to fulfilling the territorial cohesion goals outlined in the Lisbon Treaty is the size of the territorial asymmetries in labour productivity throughout the EU (Ezcurra et al., 2008), which are substantially bigger in agriculture than in the secondary and tertiary sectors (European Commission, 2008a). Through financial assistance for farm restructuring and modernization (Hennis, 2005; Dumitrache et al., 2020), the Common Agricultural Policy (CAP) has over the years sought to increase agricultural productivity as one of its main goals. However, the large disparities in agricultural productivity levels between European countries and regions have been a challenge for the CAP since its inception.

It is feasible to spot similar patterns for achieving high economic output per labour unit in agriculture (Dumitrache et al., 2021), even while there isn't a specific set of physical, technological, and human capital components and situations that boost agricultural labour productivity (Giannakis and Bruggeman, 2018; Bran et al., 2021). Moreover, when comparing countries with similar backgrounds like the 8 ex-communist EU countries, it is even easier to stop the patterns by analysing both the similarities and the differences between the 8 countries.

2 Methods

The purpose of these article is to compare the labour productivity among 8 EU ex-communist countries: Bulgaria, Croatia, Czech Republic, Hungary, Romania, Poland, Slovakia, and Slovenia - in the context of globalization – pointing out the socio-economic circumstances that determined the differences.

Analysing figure 1 we can see that in 2019, the country with the most productive labour in agriculture was The Netherlands around 72.600 EUR/ Full Time Equivalent (FTE). Also, the least productive was Romania having only around 5.200 EUR/ FTE. The EU average was around 19.900 EUR/FTE.
Figure 1. Labour productivity in agriculture by Member State (EUR/FTE) in 2019

Source: the authors, using data from https://agridata.ec.europa.eu

The 8 EU ex-communist countries that are the subject of this analysis are marked with light blue in figure 1. We can observe that all of them are below the EU average of 19.900 EUR/FTE. However, there is a significant gap between the highest performer of the 8 – Czech Republic with 16.500 EUR/FTE – and the poorest performer – Romania with 5.700 EUR/FTE. From a different perspective, the output of 3 full time workers in agriculture in Romania is produced by only 1 full time workers in Czech Republic.

Further analysing what caused these differences and gaps, we will make a comparative analysis of several indicators developed by The World Bank:

− Labour force working in agriculture
− Share of the labour force employed in agriculture
− Changes in agricultural labour and land use
− Share of agriculture in GDP vs GDP per capita
− Farm machinery per unit of agricultural land

The analysis is made on data from "Employment in Agriculture" report, published online at OurWorldInData.org.

3 Findings

One of the causes of the low labour productivity in agriculture in the 8 EU ex-communist countries can be related to the number of workers from this sector and how this number fluctuated. Figure 2 shows us the share of people of working age who were engaged in any activity to produce goods or provide services for pay or profit in the agriculture sector. All of them being emergent economies in the '90s, the 8 EU ex-communist countries lowered the share of labour force employed in agriculture most likely due to the intensification of industrialization. In the 1991 they formed 2 clusters: Czech Republic, Slovakia, Slovenia and Hungary having around 10% of the people of working age engaged in agriculture, and Bulgaria, Croatia, Poland and Romania having around 25% of the people of working age engaged in agriculture. By 2019, the 7 countries clustered together at an average of 6% (ranging from 2,66% in Czech Republic to 9,15% in Poland). Only Romania reached 21,24% after almost 3 decades of fluctuations.
Figure 2. Share of the labour force employed in agriculture, 1991 - 2019

Source: "Employment in Agriculture" report, published online at OurWorldInData.org.

Surprisingly, from 1991 to 2000, Romania increased the share of people of working age engaged in agriculture each year (exception 1996). In 2000, 45,21% of the working age population in Romania was engaged in agriculture. For almost 10 years, Romania was not aligned to the trends in the region but was doing the opposite. There are few reasons why the Romanian work age population had such a great appetite for agriculture: on one hand the collapse of the industry, high inflation rates and high unemployment oriented the work age population to subsistence agriculture done in small size family farms; on the other hand, the fall of communism, when the agricultural land was mostly state-owned, brought the agricultural land back to people. The high level of fragmentation of the agricultural land and the lack of associativeness were generated by a misconception. The novelty of private property, the freedom of choosing how to exploit the land and the expectation of becoming reach by doing agriculture determined more and more Romanians to do subsistence agriculture in the '90s.

The productivity of agriculture might have been influenced by the variation of the land used in agriculture. As we can see in figure 3, only Romania and Slovenia kept exploiting roughly the same total area as in 1991. All the other countries lowered the surface of land used for agriculture, maybe relying more on machinery and technology for a more intensive agriculture, thus increasing their labour productivity.
Figure 3. Changes in agricultural labour and land use, 1991 - 2019

Source: "Employment in Agriculture" report, published online at OurWorldInData.org.

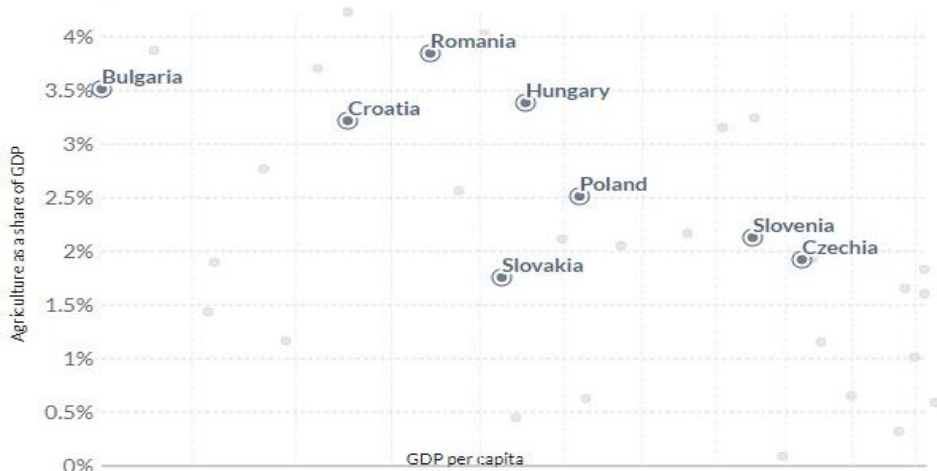
Figure 4 shows us how the wealthiest countries are also the least dependent on agriculture. For example, Czech Republic - having the highest productivity in agriculture among the 8 EU ex-communist countries, estimated at 16.500 EUR/FTE in 2019 – has also the highest GDP/capita and one of the lowest contributions of agriculture to GDP.


Figure 4. Share of agriculture in GDP vs GDP per capita, 2020

Source: "Employment in Agriculture" report, published online at OurWorldInData.org.

Figure 4 may also suggest that the more complex and performant an economy is in the other sectors, the more performant it is in agriculture too.

Another variable that may influence the labour productivity in the field of agriculture is the technological capital used in the agricultural production. It is widely known that in any field technology increases the productivity.
Figure 5. Farm machinery per unit of agricultural land, 2019

Source: "Employment in Agriculture" report, published online at OurWorldInData.org.

Farm machinery is measured in units of horsepower. This is divided by total agricultural land to give the average machinery use per 1000 hectares of agricultural land. This

indicator is presented in figure 5 which shows us that Romania and Slovakia are the least technologized with only 0,73 respectively 0,75 horsepower unit per 1000 hectares. As figure 5 shows, the most technologized country is Poland with 7,17 horsepower units per 1000 hectares, followed by Croatia with 2,81.

Analysing both figure 5 and figure 1 we can see that there is no correlation between the amount of technology (in this case farm machinery) used in agriculture and the labour productivity. For example, 1 worker in agriculture in Czech Republic produces 2.75 times more than and worker from Poland, using 6,23 times less farm machinery than the worker from Poland (measured in horsepower units/1000 hectares).

4 Discussion and conclusions

In this article we compared the labour productivity among 8 EU ex-communist countries: Bulgaria, Croatia, Czech Republic, Hungary, Romania, Poland, Slovakia, and Slovenia - in the context of globalization – trying to point out the socio-economic circumstances that determined the differences. Even if the labour productivity gaps between the 8 countries are significant (i.e., 1 worker from Czech Republic generates as much output as 3 workers from Romania), all of them are below the EU average.

We analysed 5 main variables that may have been causing these differences and gaps. It turned out that the high share of the labour force working in agriculture can be an explanation only for the case of Romania. It does not explain the poor performance of the other countries. Also, as most of the 8 countries – excepting Romania and Slovenia - lowered the surface of land used for agriculture, maybe relied more on machinery and technology for a more intensive agriculture, thus increasing their labour productivity. This variation of the land used in agriculture does not explain the poor performance of Poland, Croatia, Bulgaria and Hungary.

The technological capital used in agriculture in each country does not influence the labour productivity. It may explain the situation from Romania which has the lowest ranking both in farm machinery and in labour productivity in agriculture, but it does not explain many other cases. For example, according to the available data, 1 worker in agriculture in Czech Republic produces 2.75 times more than and worker from Poland, using 6,23 times less farm machinery than the worker from Poland.

We also compared the share of agriculture in GDP vs GDP per capita of the 8 EU ex-communist countries. The data suggest that the more complex and performant an economy is in the other sectors, the more performant it is in agriculture too. We need more evidence to support this as a conclusion. Maybe there are other variables that influence the labour productivity horizontally, across sectors. Further research may take into consideration the structure of the labour force employed in agriculture.

Abstract

Research background: Financial stability is very important for each enterprise. A financially stable enterprise can resist or handle unpleasant situations. Such situations can be a test of the existence, endurance, or the question of whether an enterprise can recover from such a difficult state. The main topic is the issue of ratio indicators and the impact of the COVID-19 pandemic on the hospitality sector.
Purpose of the article: The main aim of the paper is to describe and quantify the impact of the global COVID-19 pandemic on the hospitality industry and to assess crucial changes in the financial performance and stability of the sector considering the significant financial indicators of ex-post analysis.
Methods: To achieve the main aim of the paper, ratio analysis was used and the development of the financial indicators was measured over a 4-year horizon and mapped using a graphical analysis.
Findings & Value added: Analysis and subsequent monitoring of the development of ratio financial indicators is an important step towards knowing the extent to which the industry is financially healthy and how its activities are affected by the global coronavirus pandemic. By exposing the weaknesses, the problems can be prevented in the future, not only in the context of funds, but it can also lead to the setting out of short-term and long-term strategies and goals that will make the sector more stable and competitive even in times of crisis.

Keywords: *corporate performance; financial stability; COVID-19; hospitality sector*

1 Introduction

Financial stability is very important for the company. A financially stable company can withstand or handle emergency situations for him. Such situations can be for businesses a

---

* Corresponding author: pavol.durana@fpedas.uniza.sk

test of their existence, endurance or the question of whether they can recover from such a difficult situation. Companies that are financially secure can respond more flexibly and better to changing surroundings, the situation or legislation, but also to changes in the company itself. For such businesses, the probability of possible bankruptcy is reduced and the business risk is also minimized. By quickly and appropriately identifying the most decisive risk factors, the company could prevent adverse impacts on the company's economic results (Kliestik et al., 2022).

In order for the company to correctly evaluate its financial situation, it is necessary to carry out a thorough analysis of the company, i.e. a financial analysis, through which essential facts are determined. The company will thus find out which of these facts are its strengths and need to be further developed, or which are the weak points of the company and may be accompanied by financial problems in the future. From a time point of view, financial analysis provides a view into the past (ex-post), i.e., the company itself can evaluate how it developed, and into the future (ex-ante), which can help the company when compiling a short-term or long-term financial plan (Gajdosikova et al., 2022).

Financial analysis currently has justified importance. The COVID-19 pandemic has had significant but negative impacts on most economic sectors in all countries. Individual countries have established quarantine measures to prevent the spread of the COVID-19 pandemic and to minimize the negative effects of the pandemic (Valaskova et al., 2021). The sectors of the economy in Slovakia most affected by the pandemic include services, industry, and air transport. Gradually, operations in the production spheres were closed, as were some shops. Travel was more or less forbidden. Such a recession caused not only a high number of layoffs, a number of businesses at risk of bankruptcy, but mainly a large drop in gross domestic product in Slovakia. Businesses have been trying to survive this pandemic crisis with the smallest possible impact on their operations. They monitor the development of the financial situation regularly, i.e. at quarterly intervals, try to increase their productivity and monitor liquidity, activity, and profitability at least at their minimum sustainable values in order to stay on the market (Hlawiczka et al., 2021).

The aim of the paper is the description and quantification of the impacts of the COVID-19 pandemic on the hospitality sector and evaluate changes in the financial performance and stability of the monitored company and in comparison with the industry when monitoring ratio financial indicators in ex-post analysis.

Currently, the issue of financial analysis makes even more sense with regard to the new pandemic disease COVID-19. The COVID-19 pandemic poses a threat not only to humans, but also to small and large businesses, and thus to the global economy (Carracedo et al., 2021). The threat is made up of individual restrictions that have been set by countries around the world to try to stop the spread of the new disease, COVID-19. The goal was a vision of returning to the "good old" days before the pandemic (Castañeda-Navarrete et al., 2020).

Compared to the financial crisis of 2008, it is significantly different from the current pandemic crisis caused by the new disease of COVID-19. As Pardhan and Drydakis (2021) state, the current pandemic crisis is primarily characterized by a high decline in gross domestic product not only in developed countries, but in countries around the world. Currently, gross domestic product is said to have fallen by around 3% according to the International Monetary Fund, down from 0.1% during the financial crisis. Another difference is that the financial crisis affected all sectors of the economy negatively. During the pandemic crisis in 2020, some sectors of the economy were hit hard, such as tourism, services or the automotive industry, which were helped by the measures taken and also the closure of businesses. In contrast, however, there are sectors that have enjoyed great success and sales growth despite the pandemic, as these products were in demand. These

are sectors of the economy such as the pharmaceutical industry, the food industry, or the technology industry.

The impact of the COVID-19 pandemic, the impact on corporate finances and decision-making was addressed by Iyer and Simkins (2022), who state that such an investigation was not easy. A certain change was the publication of financial statements at quarterly intervals, i.e. the shortest possible monitored intervals, which complicated the collection of an adequate amount of information in order to create a true picture of the company's financial situation. Zhang and Zheng (2022) compared companies and found that companies with high cash reserves can face crises such as the global COVID-19 pandemic, compared to companies with insufficient cash reserves. If businesses cut payroll and investment, their cash reserves would increase during a crisis. Based on a survey of 1,400 US dividend-paying companies, Krieger et al. (2021) that 213 companies reduced the value of dividends and 93 companies did not pay dividends at all. The authors concluded that with this step of the companies, the authors concluded that these are companies that are efficient and know how to manage even in times of crisis.

Mirza et al. (2020) presented several stress frameworks that describe probabilistic phenomena in non-financial listed companies, such as an increase in the number of defaults, an increase in foreign liabilities on the liabilities side, or a decrease in asset coverage. The results of these studies indicate that the solvency of each business will deteriorate, with sales and total market value falling. The authors also investigated how they can maintain solvency and came up with the idea of deferring taxes. In the event of a downturn leading to the collapse of the business, there should be cross-support with liabilities and equity.

Ibn-Mohammed et al. (2021) addressed the impact of the global COVID-19 pandemic on the Sustainable Development Goals, which were adopted by the United Nations in 2015, to improve living conditions and nature by 2030. The goals were based on two assumptions: globalization and sustained economic growth. The authors' research pointed to the fact that current sustainable development goals are not stable against shocks caused by pandemics. The authors, Naidoo and Fisher (2020), state that two-thirds of the total goals will not be met by 2030 and even state that the fulfilment of some goals is threatened by the pandemic if they cannot mitigate the effects of the pandemic.

2 Methods

To achieve the main aim of the paper, ratio analysis of 580 Slovak enterprises operating in the sector NACE I (Accommodation and Food Service Activities) was used and the development of the financial indicators (liquidity, activity, indebtedness and rentability) was measured over a 4-year horizon. Friedman non-parametric test was used to reveal the differences in the development of the ratios and measure the impact of the global COVID-19 pandemic.

The following table (Table 1) summarizes the calculation of the financial indicators used in the analysis.

Analysing the data of all enterprises, the graphical analysis was used. The graphical analysis creates pictures of the data, and this will help to understand the patterns and also the correlation between process parameters. Often graphical analysis is the starting point for any problem-solving method. The process may be immediately understood by graphical analysis, which also improves communication and gives additional study a clear direction. It is a crucial tool for identifying the reasons of data fluctuation, which aids in understanding the process and its fundamental problems.

Table 1. Analysed financial ratios

Financial ratio	Abbreviation	Algorithm
Cash ratio	L1	Cash and cash equivalents to current liabilities

3 Results and Discussion

Based on the analysis of ratio indicators in the monitored industry during the years 2017-2020, we would like to make suggestions and recommendations for the investigated sector to improve its financial situation. In general, it can be said that despite the ongoing pandemic, businesses managed to avoid bankruptcy and get through a difficult financial situation.

When illustrating the development of cash ratio (L1) during the monitored period, we considered that the monitored enterprises achieved the desired values of the indicator (calculated average values) in 2017 and 2018. In 2020, when the environment was affected by the COVID-19 pandemic, businesses did not reach the recommended values of the indicator. Our recommendation is that businesses should strive to increase the most liquid assets, e.g., by selling a certain part of the property or by maximizing the profit that the company would achieve, e.g., by expanding the offer of its products and services (Nagy and Lazaroiu, 2022). The development of the quick ratio (L2) took a negative direction, as the companies did not reach any of the recommended values in the monitored period in even one year. By suggesting how to improve these values, we came to the conclusion that it would be appropriate to reduce the receivables that the company has (using factoring or forfaiting services) (Kovacova, et al., 2022). The development of the current ratio (L3) was also negative, since the recommended values were not reached in any monitored year. The enterprise could achieve the recommended values by increasing the value of assets, especially current assets. A reduction in the volume of short-term liabilities will also contribute to increasing the liquidity of companies in general (Figure 1).
Figure 1. Liquidity ratios (development)

In the ratio analysis of activity, companies from this sector must work on measures that will either minimize turnover times of business items or maximize the turnover of business items (Gajdosikova and Valaskova, 2022). Turnover times of business items only increased year-on-year, which negatively reflects the financial situation of businesses. Although the sales produced by businesses grew until 2019, they fell deeply in 2020 due to the pandemic. Analysing the period of stock turnover (STP), the value of the material available to companies increased year-on-year. We recommend that it possibly minimize the value by selling this material, which would increase the company's funds and at the same time decrease the costs of managing them. Considering the debt collection period (DCP), we would again recommend to the company, as in the case of liquidity, using factoring or forfaiting for a quick purchase of receivables.

This would reduce the company's receivables payment times. During the turnover period of total assets, the highest values were reached, which can harm the company, even though the values of the indicator decreased until 2019, the maximum was reached in 2020. The turnover of total assets (TAT) developed positively until 2019, but in 2020 the value decreased by more than half. Businesses are advised to increase turnover, not to increase the volume of assets, and to use all the assets available to them. Businesses can do so when the pandemic measures are relaxed, which will also cause the expected increase in sales (Gregova et al., 2021). The turnover of current assets (CAT) had the same development. It is recommended that companies increase their financial accounts, e.g., through the sale of materials or accelerated payment of their receivables. The last ratio of activity indicators was the turnover of fixed assets (FAT), which developed similarly to the latest one (see Figure 2).

By analysing the indebtedness, we assessed that the total indebtedness (TI) is in the range of 49–59 %, which means that it reaches the recommended values, and thus the companies use their own and foreign capital in a balanced way. For the self-financing ratio (SF), the values decreased year-on-year, which was undesirable for companies. We therefore at least recommend that the company increase its share capital by the deposits of the owners of the company, despite the fact that equity capital is more expensive. In this case, it would have the advantage that if the company continued to borrow capital from creditors, it would not have to be considered a risky entity (Michalkova et al., 2021). The credit debt ratio (CD) followed a similar trend, which can be a warning signal for various creditors, while bank loans were primarily of a long-term nature. It is necessary not to increase the volume of loans.
Figure 2. Activity ratios (development)

The interest coverage ratio (IC) which reaches high values, can be positively evaluated, which means that companies are able to repay loan interest. After evaluating the indicator of financial leverage (FL), it is possible to claim that companies should either increase the volume of their own resources, or increase the share capital with deposits by the business owner while maximizing the profit at the end of the next accounting year in order to avoid bankruptcy. Therefore, businesses should think about a marketing strategy that would attract more potential customers (Gajanova et al., 2021). The cash flow coverage ratio (CFC) shows high values of repayment of liabilities through cash flow for companies. Businesses are therefore advised to maximize their profits during the next period. The insolvency ratio (IR) of enterprises can be evaluated negatively, as values higher than 1 have been reached. This is the inability to pay their obligations, which was caused by the enterprises themselves. It would therefore be appropriate to reassess the volume of total liabilities or increase the receivables, e.g., by favouring payment conditions, which would achieve an advantage over the competition (Figures 3a and 3b).
Figure 3a. Indebtedness ratios I (development)
Figure 3b. Indebtedness ratios II (development)

In general, the achievement of favourable and high values of individual profitability indicators is largely influenced by the growth of corporate profits. Net profit growth can be achieved in various ways, e.g., expansion of the services offered to customers. Companies should consider what new methods or offers they can use to attract the attention of new potential customers (Ballerini et al., 2022). Furthermore, we suggest companies to increase the price for accommodation appropriately, so that it remains competitive and does not differ much from others. With this step, the company could slowly approach the financial situation it was in before the outbreak of the COVID-19 pandemic (Figure 4).
Figure 4. Rentability ratios (development)

To a certain extent, the growth of profitability indicators is also influenced by the decrease in total costs, which are part of the overall profit calculation. Companies should deal with the optimization of the volume of costs throughout their existence, because solving the issue of cost optimization is a long-term issue and it is excluded that this issue should only be addressed when the company's financial situation is threatened (Sahman et al., 2009). There are several ways in which the company manages to reduce its total costs. It would be appropriate to focus primarily on reducing the costs of the company's economic activity. When reducing labour costs, the company should consider the possibility of outsourcing. It would also be effective if businesses reduced their tax through tax write-offs. On the other hand, it is possible to use depreciation to finance business assets, which is the so-called "free capital" (Preisinger, 2019).

The financial situation and performance of companies have completely changed due to the impact of the global COVID-19 pandemic. The pandemic has affected every financial ratio we monitor. Compared to 2019, however, companies managed to increase the year-on-year values of individual liquidity. The most negatively affected indicators are activity indicators, where some values increased by more than 50% during turnover times, which only hurt the business. Turnover indicators, on the other hand, decreased by 50%, which also has a negative effect on business activity. The pandemic also hurt businesses in financing their needs, when their indebtedness increased, which meant that businesses were more dependent on foreign capital than in previous periods. Profitability indicators were also affected by the pandemic, when a negative net profit was achieved due to increasing costs.

4 Conclusions

In general, financial analysis is considered the most widely used and sought-after means by which businesses can reliably assess their financial health through various financial indicators. Ratio financial indicators are among the basic indicators of financial analysis. Their advantages are that they can be used to analyse the development of the company's financial health over time, whether based on their results it is possible to predict the future development of the company's financial situation, or whether their results are comparable to the results achieved by the industry. By evaluating the results, we came to the conclusion that the global COVID-19 pandemic had a severe impact on the development and operation of companies in the selected sector.

Prediction of the evolution of economic crime in the Slovak Republic

Jakub Durica[1,*], *Viktor Soltes*[1], and *Veronika Adamova*[1]

[1] University of Zilina, Faculty of Security Engineering, Department of Security Management

Abstract

Research background: Conventional theft and other illegal means of enrichment have recently been abandoned. Economic crime is now coming to the foray are perpetrated by educated people who know about finance. In few cases, it happens that economic crime is committed by only one person; in most cases, it is an organized group that has an established modus operandi and has been committing this crime for a long time. Economic crime causes economic damage to the state, legal and natural persons. It is mostly a latent crime, i.e. it leaves no visible criminal traces and is therefore difficult to detect.

Purpose of the article: The main objective of the authors of the article is to predict the possible development of economic crime up to 2027. The prediction of crime will reflect crime trends from 2002 to 2021, when we already know the number of economic crimes for each year.

Methods: The above analysis of publicly available sources will be used in the preparation of this article. Synthesis, induction and deduction will also be used. Last but not least, prediction will be used.

Findings & Value added: The findings of the study, i.e. the prediction itself, will serve state agencies such as the police force, the financial administration. Based on the results of the study, various prevention programs can be applied to reduce economic crime.

Keywords: *crime; economic crime; evolution; prediction*

1 Introduction

Crime and victimization occur in every society, although relative differences in their kind and extent are inevitable (Jibat and Nigussie 2015).

The phenomenon of economic crime remains an ongoing challenge despite all efforts to combat it. The rules that society creates for the economy and its participants are often broken. Corruption, collusion, fraud, tax evasion and other forms of misconduct are widespread and costly (Kertesz and Wachs 2020). The main reasons for the emergence and existence of economic crime and fictitious business are: the imperfection of legislation

regulating economic activity, the high level of corruption, tax evasion, the control of corrupt persons in the main sectors, the low professional level of law enforcement police officers in detecting, documenting and investigating these crimes (Krysovaryy 2021). According to Argentiero (2018), economic crime has shifted significantly in recent years from Backer's economic crime to a more flexible approach where many demographic and socioeconomic variables are taken into account

Economic crime is an ever more commonly used term without a strict definition, which is generally thought to include fraud, corruption, money laundering, intellectual property crimes and some of the cybercrimes that facilitate them (Button 2021). There is currently no settled definition for the term economic crime. This is because each scientist defines economic crime in terms of his or her area of study. It is the same with similar terms such as "crimes in the field of economics", "economic crimes", "shadow economy", "criminal economy", "economic crime" (Cherniavskyi, 2021). Economic crime together with organised crime belong to work related crime (Vestby, 2021).

Economic crime is not a new social and criminal phenomenon in our lives, but it is still not sufficiently, fully and in depth explored in the context of the dynamic changes that are emerging in the world. Economic crime is constantly evolving and is increasingly difficult to detect. This is because economic crime has moved online, and the use of computers, computer networks or other forms of information and communication technology is required (De Nicola 2022). It is quite clear that such a situation is not acceptable for the practice of the state's influence on economic crime, nor for the researchers who are trying to learn about its nature and modifications. Therefore, in the world society there has come the need to introduce a uniform standard of classification of economic crimes (Barzykina, 2016). Levi (2017) states that economic crimes have recently been occurring primarily in cyberspace. Therefore, quantifying the specific damages is problematic.

According to Volobuiev and Schevchenko (2019), the variety of ways of committing economic crime, the use of different technologies, as well as a wide range of modus operandi lead to considerable difficulties in their investigation. Economic crime has improved considerably over the last 50 years and detection is becoming more difficult every year. Kozak (2018) considers economic crime to be property crime but also crimes in the economy. The author views as economic crime the interference in the property, management of the economy, which are committed by the basic stop social position in the structure of the economic for the purpose of unjustified enrichment. Gaspierik (2010) states that the motive for economic crime, as for property crime, is the acquisition of unjustified pecuniary gain. The majority of economic crimes are defined in Act No. 300/2005 Criminal Code, specifically in Chapter V. Some economic crimes are also defined in Chapter VI of the Criminal Code. According to Recommendation No. R (81) 12 of the Committee of Ministers to Member States on Economic Crime, economic crime includes environmental crime. In the foreign literature (Argentiero 2018) it is possible to read about three determinants that we classify as economic crime:

− property crime,
− fraud,
− usury.

Alvesalo and Tombs (2004) say that economic crime can be controlled even today, when globalisation is coming to the fore. According to Draca and Machin (2015), the labour market and wages are to blame for the increase in crime. Because if work was sufficiently rewarded, people would not need to commit crimes for economic reasons. Another possibility for why economic crime exists is the transformation of organized crime from violent crime to economic crime, where we can also include money laundering (Levi 2015).

According to the statistics of the Ministry of the Interior of the Slovak Republic from 1989-2020, a total of 389,676 economic crimes were recorded in Slovakia. Soltes (2022) talks about dividing the trend of development into 2nd periods. The first period from 1989-2021, and the second period from 2002 - present. The reason for the division into 2nd periods is the change in the Criminal Code and the resulting increase in economic crime in 2002. In terms of fundamental economic models, the reduction in crime can be said to be driven by increased resources for policing and crime prevention (Machin and Marie 2011). Currently, the clearance rate for economic crimes da hovers around 50 %. Statistics on the status and clearance of economic crime in the 2nd period, i.e. from 2002 to 2001, can be found in Figure 1.
Figure 10. Statistic of economic crimes (MinV, 2022)

2 Methods

In order to predict the evolution of economic crime, we will consider the number of economic crimes from 2002, i.e. from the change of the Criminal Code, to 2021. Predictions since 2002 are also supported by Soltes (2022), who says that the change in the Criminal Code in 2002 significantly distorts the portrayal of the evolution of economic crime in the Slovak Republic. On the results of the prediction, the competent authorities will be able to develop and determine appropriate preventive measures.

3 Results

As Figure 1 shows, economic crime remained roughly flat until 2013. Since 2014, we have seen a slow decline in economic crime until 2020. In 2021, the number of economic crimes increased slightly. The clearance rate for economic crime has been in the range of 55%-45% from 2002 to the present.

In forecasting we will take into account 3 models, namely:
- lower confidence limit,
- prediction,
- upper confidence limit.
  See Figure 2 for a prediction of the number of economic crimes by 2027.
Figure 11. Prediction of economic crime

As we can see, the forecast is downward sloping, as indicated by the trend of the previous years. The upper confidence limit is slightly upward sloping, which may result in a slight increase in economic crime in 2021. The lower confidence limit reaches a negative number, which is not possible in this context, so we can say that there should be no economic crime in the Slovak Republic from 2026 onwards, but we do not agree with this.

Next, we will predict the number of cleared cases of economic crime. As in the previous case, the prediction will be until 2027.
Figure 12. Prediction of clarified economic crimes

As we can see, we can see that even for the clarified cases, the prediction has a downward trend, as in previous years. The upper confidence limit has a significant increase in cleared crimes until 2023, but stagnates from 2024 onwards. The lower confidence limit has a downward trend, but here we do not get to 0, which is inconsistent with the lower confidence limit for the number of economic crimes. We see that the economic crime clearance rate is decreasing, but this is not a negative phenomenon as the number of economic crimes is also decreasing.
Figure 13. Prediction the development of economic crime and crime clearance

As we can see, the trend of economic crimes is decreasing, which means that the number of solved cases is decreasing every year. However, clarity has an increasing trend and in 2027 clarity will reach 69 %, which is an increase of almost 30 % compared to 2021.

4 Conclusion

Economic crime is one of the most significant types of crime. Its consequences can have an impact on the functioning of individual states. The reason why economic crime is a serious problem is because it is largely latent and difficult to detect. In the Slovak Republic, economic crime is defined in Act No. 300/2005 Criminal Code. The statistics of economic crime in the Slovak Republic can be divided from 1989 to 2002 and from 2003 to the present, due to the amendment of the Act in 2002. The article contains a prediction of economic crime until 2027. The prediction results in a decreasing trend of economic crime. The trend in the clearance rate of economic crimes, which is up to 70 % based on the prediction, is encouraging.

Globalization phenomena on the Slovak financial market profiling the credit cycle - a view of households

Igor Dvornicky[1], and *Kornelia* Belickova[1,*]

[1] University of Economics in Bratislava, Faculty of National Economy, Dolnozemska cesta 1, 852 35 Bratislava, Slovakia

Abstract

Research background: In the development of modern society, we increasingly witness credit booms and excessive loan growth. A typical example is the case of Slovakia, where loans to households have been growing the fastest in Central and Eastern Europe for more than a decade, even after the end of the growth phase of the economic cycle. Indebtedness of Slovak households changed from being the least indebted, when it settled between the top rankings within the EU. A similar specificity in Slovakia also occurred with interest rates, which changed from the highest in the region to the lowest.
Purpose of the article: Despite the fact that the profiling risks for the territory of the Slovak Republic represent to a large extent an unprecedented development, economic theory recognizes similar development scenarios. This allows us to better identify and name these phenomena. At the same time, our intention is to verify whether the competitive war of banks leads to frenzied household indebtedness regardless of economic development.
Methods: We use a multiple linear regression model using the instrumental variable method (IV Regression) to test the derived hypothesis. To estimate the model, we use the steps of statistical tests such as the Hausman test, the Method of Least Squares (OLS), the Pesaran-Taylor test, the Breusch-Godfrey test and the Cochran-Orcutt correction.
Findings & Value added: In the private sector, we capture multiple phenomena such as the transfer of risks by retail banks to the state through their unprecedented risk appetite; sharing the collective guilt of senior management of financial institutions by copying given trends; triggering a mortgage war by banks in an environment of excessive competition; and finally, as a result, the herd behaviour of consumers with disproportionate indebtedness.

Keywords: *share the Blame effect; search for yield; herd behaviour; mortgage boom; bubbles and bursts*

1 Introduction

The environment of credit booms requires a search for their triggers and understanding the causes of (disproportionate) household indebtedness should be an important concern for policy makers and regulators. The most significant generalization of the effects on the credit cycle are *government interventions* in the free market reported in the economic literature. Through the monetary policy of central banks, the interest rate market is influenced, which also causes excessive credit growth. While, interest rates also fell abroad, despite this, the trend of credit growth in neighbouring countries during the observed period did not turn into excessive growth and was even often rather the opposite. In Slovakia, economic experts considered the growth phase of the economic cycle with favourable macro prospects and positive sentiment as the main reason for the stimulus of the credit rally. However, the authors of the paper proactively pointed out that the new drive in the unceasing growth of household indebtedness is primarily driven by the artificially induced pricing of interest rates, as part of the mortgage war in an environment of saturated retail bank competition. In addition, external financial intermediaries play an important role here, whose predatory offer and individual approach to the client act as a multiplier effect. In favour of the stated postulate, the overall rate of growth of loans to households in Slovakia, which is still excessive even after the cooling of the domestic and world economy, also testifies. First of all, the supply strategy contributes to this. The business model of the retail banking sector is focused on providing loans with little room for diversification of activities. This intensifies the competition between them and pushes for the reduction of interest margins, which are among the lowest in the Eurozone. In some months of 2019, they also reached the lowest rank in the monetary union. The phenomenon of low profitability is still present in the eurozone banking sector. The main factor was the decrease in income from the retail sector due to falling interest margins. Until 2016, the Slovak banking sector was one of the most profitable in the region. In the longer term, the attractiveness of Slovak banks from their parent groups' point of view may decrease, which may lead to a decrease in investments on their part. In general, high indebtedness or its rapid growth causes higher losses for banks in times of crisis. However, the experience of the last crisis indicates that there is also a connection between the growth of indebtedness before the crisis and the drop in household consumption during the crisis. Simply put, the higher the changes in the share of household debt to GDP in good times, the deeper was the decline in household consumption in bad times, and thus its lower contribution to GDP. According to Edwards and Mishkin, the traditional business of banks - making long-term loans and financing them by issuing short-term deposits - has declined in recent years. These developments raised concerns that more banks would fail or be forced to take greater risks to remain profitable (1995a). It is the unprecedented appetite for credit and less prudent risk management by the banking houses operating in the territory of the Slovak Republic that is ultimately a phenomenon that we are witnessing in the current development. The IMF also places great emphasis on the impact of low interest rates on financial stability in its analyses. The era of cheap money also has an effect on excessive indebtedness in certain segments of the corporate sector. The long-term persistence of interest rates at low levels, in many cases historically low, is one of the main sources of risks for financial stability. Such conditions create motivations in the real economy and financial markets leading to the accumulation of imbalances and an increase in vulnerabilities. In the event of an economic downturn, these characteristics subsequently amplify and accelerate negative trends and deepen crisis development (2019). In addition to the mentioned mechanisms, low interest rates and unconventional currency operations can have other side effects. The role of quantitative easing in deepening income and property inequality through increasing asset prices, which are concentrated amongst the wealthier

population, is becoming more and more discussed. It is not effective for the development of the economy's long-term potential that low interest rates help unpromising businesses to survive financially and thus hinder the process of the so-called *creative destruction*.

2 Collective optimism and the herd effect as the driving engine of the boom

Despite the assumption that it is natural for all market agents to achieve the greatest possible profit and progress, the occurrence of the named phenomena, which at first glance evoke optimism and maximization of growth, may not ultimately represent a positive effect. The word boom evokes the growth of a certain phenomenon, or its onset at a rapid pace. Based on this, we can say that for further assessment of its usefulness, it also matters what phenomenon it will be used with and what is its trigger. The baby boom among economically active society is perceived positively. Likewise, the term is often associated with a technological boom, which advances the overall development of our civilisation. And what about the mortgage boom, is it a positive phenomenon? Housing loans based on collateral are among the most effective types of loans and help households, as market agents determining consumer trends, to develop. Anyway, economic metrics consider the growth of selected statistical indicators depending on the development of associated groups of indicators. In economic jargon, we then interpret a boom as artificial growth, when some assets can grow beyond the corresponding macroeconomic fundamentals, and in that case, we can talk about the formation of bubbles. In the end, the best-known booms remain etched in history on the example of the sectors mentioned above. The dot-com boom, also known as the dot-com bubble, was a technology stock market bubble in the late 1990s (during a period of massive growth in Internet use) that caused many online service companies to go bankrupt. And of course, the bursting of the US subprime bubble in mid-2007, which grew into a global financial and debt crisis. Optimism as such would be interpreted negatively by few, not even with a collective sign. However, it can be a certain problem if it causes the private sector to insufficiently assess risks, the appropriateness of investments, or if it develops into herd behaviour. According to Chari and Kehoe, there is a general awareness of the association of financial crises with herd behaviour, which they confirm in their study (2003). Kaminsky (1999), Calvo and Mendoza (1996) identify the presence of herd behaviour with the emergence of crises as a significant part of the random component where the main reasons for the crisis were considered to be mainly bad development of macro indicators. The most common cases of herd behaviour, many observers cite large trends in the stock market, when individual investors join a crowd of others rushing to enter or exit the market. According to Brunnermeier, these episodes often begin and end with periods of *frenzied buying* (bubbles) or *selling* (crashes) and are driven by specific emotions - *greed* during bubbles and *fear* during crashes (2001). This phenomenon was already noted by Keynes (1936) when he further compared the behaviour of investors in the asset markets to the famous, generally known example of a "*beauty contest*". With our analysis, we have a unique opportunity to present the phenomenon of the mortgage boom, which occurred in the territory of the Slovak Republic from April 2016 and continues in a transformed form in 2022. The environment of unprecedentedly low rates and the mortgage war of banks has changed the economic term of the *willingness to borrow* (more or less) into a *herding effect* and frenzy by the urge to take out a loan and own real estate. Indebtedness of Slovak households reached the highest values amongst the countries of Central and Eastern Europe. While Slovak clients often reach a higher level of debt when granting a loan than the limits allow abroad. A high level of indebtedness brings several risks; the vulnerability of households to possible shocks (decrease in income, loss of employment, etc.) increases. Excessive debt growth also increases the likelihood of

financial crises and reduces the potential for economic growth. The growth of indebtedness in Slovakia far exceeds the growth of favourable economic fundamentals. The year-on-year growth of loans to households, as well as the growth of real estate prices, has been a double-digit number for several years. With such a combination, economic theory already assumes the possible formation of bubbles. The most significant risk is associated with a possible overvaluation of assets, primarily as a result of the long-term period of low interest rates and quantitative easing. The mortgage war of banks, which plays a major role in the given boom, is also proof that herd behaviour does not only concern the household sector, but also the private sector (in our case, retail banking) is subject to it in its management decisions. Scharfstein and Stein (1990) point out that there is a phenomenon of sharing the collective guilt of managers (so-called *share-the-blame-effect*) as part of herd behaviour in the management of enterprises. If there is a social atmosphere of performing well while taking care of financial stability, it also motivates executive managers across the market. However, this applies even if one starts taking risks, which can threaten financial stability as a whole. In the case of banking houses, the effect of transferring risks to the state in an effort to obtain higher returns through risky investments is also documented. Bagus (2008a), therefore state the enormous influence of the "big player", which in this case is the ECB, which has it all in its hands. On the side of investors, the long-term low interest rates signed the so-called *search for yield* phenomenon. Low market yields push mainly institutional investors bound by achieving a predefined valuation to buy ever riskier assets in an attempt to fulfil these goals. The risk parameters of the portfolio of investment funds, pension funds or insurance companies have been at an elevated level for a long time. In recent months, this trend has become even more pronounced. These entities try to find more profitable assets by extending the duration of the portfolio, buying issues with a lower rating, or investing in illiquid asset classes. However, the tax for this activity is an increase in the risk of their balance sheet in several dimensions – interest, credit and liquidity (NBS, 2019, p. 17). Bagus (2008b), based on studies, sums up three other significant areas through which the spreading optimism caused by government incentives can influence social events. They are:

1. *As a result of the boom, the accounting profits of companies increase*. These misleading profits, as he further describes them, give rise not only to the feeling that the situation in the economy is in order, but also that it is a period of great prosperity and real growth. This further increases the optimism, as a result of which even the general population can invest in the asset market to a greater extent, fuelling the boom even more.

2. *During this boom, the belief is often spread that credit expansion makes it possible to sustain increased production without having to forego consumption.* Euphoria permeates the economy as people assume that it is possible to increase production without having to save in the first place. They also see their savings in debt. Developments in the financial markets, as well as the real estate market, seem to be safe, as they show growth. Therefore, investors continue to speculate.

3. *Boom is transforming the business environment.* Rising asset prices attract more and more investors, and entrepreneurial creativity and effort are directed towards asset price markets. Due to the flow of money into these asset price markets, prices continue to rise, further increasing optimism. People may leave their jobs to speculate in the asset price market, where profits appear to be made more easily than in their original jobs.

3 Methodology

Our goal in conducting a quantitative research study was to determine the relationship between one category characterized as Dependent variable - DV and the other category Independent variable - IV within the population - Slovak households. For the interest of

investigating the dependence of two or more quantitative variables, we have several statistical tools at our disposal. Since we are working with cardinal variables in our hypothesis, our choice is narrowed down to the two most suitable methods, either the correlation method or the linear regression method. With the help of linear regression method, not only we can examine the causal relationship between two or more variables, we can also calculate it exactly. Furthermore, we can determine the size of the influence and even determine the expected values of the dependent variable if we know the value of the independent variable (Greene, 2019a).

4 Results and work procedures

4.1 From the willingness to borrow to the frenzy in household lending

The term *willingness to borrow*, commonly used in Slovak analytical studies and comments, expresses the willingness of households to enter into a credit relationship and thus presents the development of new increases volume of loans depending on the selected period, which can also be examined from different viewpoints. If, within the credit cycle, we experience a disproportionate growth in household indebtedness that grows above the related fundamentals, we are talking about a growth imbalance, which is mostly associated with a credit boom. To expand the terminology of this phenomenon, we use the term *crowd frenzy in crediting the population*, while further investigating its causes. Historical development supported by analytical studies formulate postulates about the dependence of development in the real economy and the credit cycle. In broad terms this linear relationship is logical, more specifically, we can then talk about the examination of more detailed relationships and reactions of the credit market to fluctuations in the national economy. During the research activity, specifics such as the short history of the Slovak Republic with a lack of fluctuations, the underdeveloped financial market or the short history of the modern credit market must be taken into account. Separately, we note that it is also necessary to work with the cultural element as the mentality of nationalities may vary, which could be confirmed by fellow ethnographers, and it can also affect financial decision-making. This fact limits us when formulating conclusions when examining the relationships concerned by relying on the results of foreign studies. Finally, let's mention that financial decision-making falls under the act of human action, which, in addition to the level of financial literacy, is not always rational, subject to emotions, can be impulsive, and is influenced by values that also evolve over time. In view of our analysis, we consider scientific research in this area to be important and establish a derived hypothesis.

H: Availability and cost of loans are more important determinants for households than good times.

The term *good times*, commonly used in analytical studies and commentaries (e.g., of regulator), generally expresses the growth phase of the economic cycle with macro-fundamentals conjuncture, good consumer sentiment, with other favourable prospects. By *the availability and cost of loans*, we understand the release of banks' credit risk and low interest rates for housing loans. For testing the hypothesis, we choose a multiple linear regression model, as we need to identify the effect of the variable interest rate of housing loans on the dependent variable of volumes of housing loans and purify this effect from the influence of other macroeconomic factors.

4.1.1 Data used

We expressed the financial decision-making of households in the area of housing loans using the variable *volume of new loans* in thousand. EUR, which acts as a dependent variable. To test the hypothesis, we examined the dependence of the demand for loans on *the interest rate on housing loans*. Other independent variables were *ESA employment, GDP in CP* and *the real wage index*, which we used to express the economic cycle. An additional variable was *the interest rate of consumer loans*. Supplementary variables, also called instrumental variables, are used when it is necessary to find variables that do not depend on the random component of the equation, but are correlated with other explanatory variables (auxiliary variable method known as IV Regression). The data frequency was quarterly in the time period from 2008Q1 to 2020Q4.

4.1.2 Data preparation

The GDP variables in CP, ESA employment and the real wage index are in the form of year-on-year changes compared to the same period last year – called *romr*. Of this, GDP and wages were adjusted for inflation using *the HICP consumer price index*. We recalculated interest rates to year-on-year changes, thereby treating the effect of seasonality. We recalculated the volume of loans in SKK, from before the introduction of the euro currency, using the exchange rate and comprehensively adjusted for inflation using the consumer price index (HICP). We expressed the interannual changes of these volumes in the form of logarithmic differences. We used this adjustment so that changes in loans could also be expressed as percentage changes (and thus appropriately compared with other variables). Makuch evaluates the transformation of data before entering the model positively and describes it as an innovative element (2016).
Figure 1. Preview of graphs of transformed variables and their visualization over time

Source: own processing based on the output in the Gretl program (2022)

Description of variables:
ld_ubyv_ix - logarithmic difference in the volume of loans compared to the same period last year,
d_rbyv - % change in the interest rate on housing loans compared to the same period last year (romr),
d_rspot - % change in the interest rate of consumer loans compared to the same period last year (romr),
romr_hdp - % GDP change,

romr_zam - % change in employment,
romr_mzd - % change in real wages.

4.1.3 Statistical tests

The different nature of data and types of variables contribute to the variability of potentially applicable methods. As we indicated earlier, we want to express the values of our regression parameters as well as the relations between variables X and Y using a computationally easy function that shows good approximation properties, which is fulfilled by the method of least squares (OLS). However, the linear model must meet several assumptions, on the basis of which the estimation of the model using the OLS method is unbiased and efficient. Heteroskedasticity and rank correlation are often present in econometric models, which (among other things) results in a distorted estimate of the standard deviations of the estimated coefficients and thus we can make wrong conclusions regarding the significance of the regression coefficients (Greene, 2019c). In these steps, we use a test statistic, which is a previously (appropriately) determined function of sample data. The subsequently calculated statistic value serves to decide whether the null hypothesis will be rejected or not (significance testing of H_0).

4.1.4 Step 1) Hausman test for endogeneity of regressor

An important purpose in combining time-series and cross-sectional data is to control for individual-specific unobservable effects (aka "errors") that may be correlated with other explanatory variables. Using exogeneity restrictions and the time-invariant characteristic of the latent variable, we derive a test for the presence of this effect (Hausman and Taylor, 1981). The Hausman test (also called the Hausman specification test) detects the presence of endogenous variables in a regression model. Endogenous variables exhibit values that are determined by other variables in the system. The presence of endogenous regressors in the model will cause ordinary least squares estimation to fail because one of the assumptions of OLS is that there is no correlation between the predictor variable and the error term. In this case, instrumental variable estimates can be used as an alternative. However, before deciding on the best regression method, you need to determine whether the predictor variables are endogenous (ibid). In step 1) we verified the exogeneity of the independent variable *d-rbyv* with respect to the dependent variable *ld-ubyv-ix*. For this, the auxiliary variable *d-rspot* was suitable, which we used as an instrument (IV) in a two-stage regression (two stage least squares TSLS) with independent business cycle variables. The null hypothesis assumes that the estimates using OLS are consistent, whereas the alternative rate with estimates using the instrumental variables estimator (IV estimator) (Adkins, 2018a).
   Null hypothesis
   H_0: There is no correlation between "errors" and regressors
   Calculation result:
   Asymptotic test statistic: Chi-square (one degree of freedom) = 3,4644
   with P value = 0,0627032
   Since the test is not significant (p value > 0.05), we conclude that the residuals are independent of the explanatory variable *d-rbyv*, which we can consider an exogenous variable for the needs of the given model. At the same time, we can use OLS (ordinary least squares) regression to estimate dependence).

4.1.5 Step 2) Pesaran-Taylor test for heteroskedasticity

One of the assumptions of the linear model is the same value of variances of the random component u_i for different values of the explanatory variable x_{ik}. It is referred to as the condition of homoscedasticity or constant variance of a linear model. If the values of the variances are not the same, homoscedasticity is not fulfilled and a phenomenon known as heteroskedasticity occurs. In such cases, the results of the model estimation without taking this disorder into account cannot be verified, as the statistical tests are inadequate. Heteroskedasticity is therefore the inconstancy of the dispersion of random disturbances and residuals, and in the event of its occurrence, even the method of least squares would be inappropriate (ibid). There are several diagnostic tests for heteroskedasticity in IV regressions, the most suitable ones are followed by Pesaran and Taylor (1999), whose experimental study derives an improved test that was also adopted by the Gretl program.

Null hypothesis
H_0: constant variance is present
Calculation result:
Asymptotic test statistic: $z = 1{,}14499$
with P value $= 0{,}252213$

Since the test is not significant (p>0.05), we accept the assumption of constancy (equality) of variance.

4.1.6 Step 3) Serial correlation test (Breusch-Godfrey's)

In linear regression models, independent errors are assumed, therefore it is important to be able to test the presence of autocorrelation of errors in linear regression. We are talking about the serial dependence (correlation) of random disturbances or residuals. Autocorrelation is thus understood as a dependence between two or more values of one variable arranged in time (Greene, 2019d). If the perturbations of a linear model are autocorrelated, the least-squares estimates are biased and generally inconsistent. For this reason, it is important to have tests against autocorrelation available. In our serial independence test, we use the Breusch-Godfrey test, also known as the LM test (*Lagrange Multiplier test*) or its extended version, the LMF test (*The Lagrange Multiplier F*) (Breusch, 1978). Kiviet (1986) described that the standard LM test too often rejects the true null hypothesis, which is solved by the F-test form of the statistic, which has better statistical properties. First-order serial correlation test.

Null hypothesis
H_0: there is no serial correlation (autocorrelation is not present)
Alternative hypothesis
H_A: serial correlation is present (presence of autocorrelation)
Calculation result:
LMF test statistics $= 6{,}33454$
with P value $= P(F(1, 41) > 6{,}33454) = 0{,}0159517$

The test is significant (p=0.016<0.05), so we reject H0 and serial independence. We have to correct the solution for serial dependence.

4.1.7 Step 4) Estimation of the model (COILS - Cochran-Orcutt iterated least squares)

Since the basic assumption of the linear regression model is uncorrelated random components. This means that the random components from two arbitrary observations must be independent, in the case of autocorrelation even the least squares estimator would be ineffective. We must therefore find another estimation procedure or modify the least

squares method in order to obtain an acceptable estimator of the parameter vector. Given the results of the tests in steps 1-3, the appropriate solution will be to use the method of least squares with the Cochran-Orcutt correction for serial dependence. In this way, we will estimate the model of the correlation investigated and interpret it (Cochrane and Orcutt, 1949). The Cochrane-Orcutt procedure is applied by taking quasi-differentiation or generalized differentiation so that the sum of squared residuals is minimized. Since we have the dependent variable in logarithmic form, we have to convert the coefficient estimates into logarithmic ones. This gives us the interpretation of the coefficients: Percentage decrease/increase in the dependent variable for a unit change in the explanatory variable. Since the explanatory variables are also percentage year-on-year changes, we get the interpretation of the percentage change of the dependent variable for the percentage change of the corresponding explanatory variable.

Cochran-Orcutt method, using data for the period 2009:3-2020:4 (T = 46)
Dependent variable: ld_ubyv_ix
rho = 0.621302

Table 1. Auxiliary calculations.

	Variable	Original coefficient	Std.error	T-ratio	P-value	Rounded coefficient	Recalculated coefficient
1	const_β_0	−0,173079	0,0993654	−1,742	0,0890	-0,173	-15,89
2	d_rbyv	−0,495926	0,135077	−3,671	0,0007	-0,496	-39,10
3	romr_zam	0,0413319	0,0316646	1,305	0,1991	0,041	4,22
4	romr_hdp	0,0216751	0,0148161	1,463	0,1511	0,022	2,19
5	romr_mzd	−0,0186760	0,0161930	−1,153	0,2555	-0,019	-1,85

Source: own processing, according to output in Gretl (2022)

Interpretation:

1. Means the trend of the year-on-year % change in the volume of loans while keeping other variables unchanged. However, the coefficient is not statistically significant (p-value > 0.05).
2. Means a % decrease in the volume of loans with a 1% increase in housing loan interest. The coefficient is statistically significant (p=0.0007<0.05).
3. Means a % increase in the volume of loans with employment growth of 1%. The coefficient is not statistically significant (p-value > 0.05).
4. Means a % increase in the volume of loans with a GDP growth of 1%. The coefficient is not statistically significant (p-value > 0.05).
5. It means a % decrease in the volume of loans when the real wage increases by 1%. The coefficient is not statistically significant (p-value > 0.05).

Table 2. Statistics based on quasi-differentiated data.

Statistics	Coefficient	Statistics	Coefficient
Sum squared residuals	1,388402	S.E. of regression (std. error)	0,184020
R-squared	0,639459	Adjusted R-squared	0,604284
F(4, 41)	4,207716	P-value(F)	0,006037
rho	0,121676	Durbin-Watson	1,711090

Source: own processing, according to output in Gretl (2022)

The coefficient of determination, denoted as *R-squared* in the Gretl system, expresses how much of the variability of the dependent variable can be explained by the regression model.

However, the visualized R^2 statistic is primarily constructed for estimating a simple linear model. By adding independent variables to the multiple linear regression model, there is a decrease in the value of the total variability of the residuals (ESS) and an increase in the value of the coefficient of determination R^2. The Gretl program therefore offers the *Adjusted R-squared* function, which corrects the resulting difference (Adkins, 2018b).

The value of $R^2 adjusted = 0{,}604$ finally means that *the model explains about 60.4% of the variability in the demand for housing loans*.

4.1.8 Diagnostics of the suitability of the used model (Common factor test)

We will verify the suitability of the used model using the common factor test. With this test, we verify the assumption that the correction term rho, which we use in quasi-differentiation, is the same for all variables in the vector X (Hendry and Mizon, 1978).

H_0: rho is the same for all variables in the vector X
H_A: rho is not the same for all variables in the vector X
Test statistic: $F(4, 36) = 1.43918$, with p-value = 0.24107

We can see that the test is not negative (p-value > 0.05), so we consider the assumption to be fulfilled.

4.1.9 Evaluation of the hypothesis

Based on the results of statistical modelling, we can conclude that the hypothesis was confirmed. Taking into account the impact of macroeconomic developments in the monitored period, it was shown that the demand for mortgages is significantly dependent on the interest rates. This dependence is (as expected) negative. Moreover, with an increase (decrease) in the interest rate (IR) by 1%, we can assume a decrease (increase) in the volume of loans by approximately 39%. We can also show the dependence in a table (while leaving the other variables in the equation unchanged):

Table 3. Change in the volume of loans depending on the projection of the change of the IR.

% change in IR	1,2	1,0	0,8	0,6	0,4	0,2	0,0	-0,2	-0,4	-0,6	-0,8	-1,0	-1,2
% change in the volume of loans	-44,8	-39,1	-32,7	-25,7	-18,0	-9,4	0,0	10,4	21,9	34,7	48,7	64,2	81,3

Source: own processing (2022)

5. Discussion and proposed solutions to the results of the derived hypothesis

Favourable macroeconomic data, the growth of nominal wages and, as the testing of our hypothesis shows, especially the impact of the drop in interest rates had a great influence on the exceptional growth of indebtedness to the private sector in Slovakia. The willingness of Slovaks to take on debt has thus grown into a phenomenon that we refer to as *herd behaviour* in behavioural economics. At the same time, the year-on-year growth of loans to households has been growing at a double-digit rate for several years and is approaching the level of 50% debt in relation to GDP, which not only keeps the local regulator on the lookout, but also activated international attention and threats from rating agencies.

The environment of extremely low interest rates, which has been a defining situation on the Slovak financial market for a long time, pose several risks for financial stability. This mainly concerns the excessive growth of household indebtedness, the long-term impact on

the deterioration of the profitability of banks and insurance companies, increasing sensitivity to the economic cycle, increasing pressure on real estate prices and the necessity of a shift to riskier or less liquid investments in mutual funds.

We consider the impact of excessive competition in the banking sector, or their current business strategy and remuneration policy, primarily for external financial intermediaries, to be a major risk. Banking houses operating on the Slovak market have been solving margin shortfalls for several years by massively lending to households, significantly reducing the risk policy and building a portfolio of extremely cheap loans, which imposes risks to the functioning of the real economy. Therefore, we conclude that we have noticed a phenomenon of moral hazard in our territory embedded in the sharing of the collective guilt of executive managers (see "share-the-blame-effect").

Edwards and Mishkin (1995b) argue that the excessive risk taking observed in the 1980s in the US was a response by banks to the erosion of profits due to competition from financial markets. This competition has reduced their cost advantages in raising funds and undermined their position in the credit market. Feng deals with the issue in more detail, grouping studies from the 1980s, focused on the American banking system, testing the hypothesis whether higher competition (of the described type) is correlated with a higher frequency of banking crises (2018). The author describes the testing of this hypothesis on the one hand as empirically difficult and the impact on the real economy is often unclear, but at the same time, he collects enough evidence and studies by scientists in favour of this claim. He tests the hypothesis himself in the situation of a major financial crisis. The cross-sectional differences in competition on the local mortgage market versus the value of local real estate and the fluctuations of these values confirm the willingness of banks in economic competition to take on higher risks disproportionally to security. He further finds strong evidence that banks in the highly competitive US environment of 2000-2005 were willing to massively lower their mortgage risk standards compared to banks in less competitive environment.

The ECB study also confirms that the high level of competition in banking (within our territory in retail banking) can increase the accumulation of risks. Excessive competition and rivalry amongst banks can result in reduced risk aversion and accumulation of risks in the banking sector with subsequent impact on the real economy (Carletti and Hartman, 2002a).

At the same time, measures to prevent the transfer of risks by banking houses to society were absent in the legislation for a long time, such as preventing irresponsible lending to households in an environment of high competition in Slovak retail banking sector. In their study, Carletti and Hartman document the fact that the relationship between economic competition, risk arising from liability and optimal regulation has been ignored not only by the policy makers, but also by the economic experts and the literature. Based on an in-depth study of the world literature, they state that most contributions on bank governance and systemic risk pay very little attention to the strategic interaction between banks, ignoring the effects of different market structures on their financial stability and on the efficiency and effectiveness of macro-prudential policy measures. Most traditional models assume that banks operate in a perfectly competitive environment or in a monopoly setting (2002b).

The long-term persistent growth of indebtedness, which was excessive in recent years, significantly deepened the systemic nature of the risk associated with household indebtedness. In order to mitigate the further accumulation of these risks in the future, it is therefore important to moderate the growth rate of household indebtedness, at least to the level of neighbouring countries. *Even in such a case, however, the above-mentioned risks resulting from the current excessive growth of indebtedness will remain present* (Kalman, 2018).

We conclude that since most changes in consumer behaviour can lead banks to non-traditional activities and moral hazard risks, the main role in protecting financial stability must

be played by proactive and effective regulation, then the new business environment can be regulated as effectively as the original one, associated with traditional activities of banks.

Indebtedness can be effectively mitigated through rental housing. The underdeveloped sector of non-commercial rental housing also contributes to the rapid growth of mortgages. Only 11% of households live in a rental property. The preference for buying one's own real estate with a housing loan (even by less creditworthy groups of the population) leads not only to the prevailing social model of real estate ownership, but also to the limited offer of real estate for rent, especially subsidized apartments. The supply of rental housing is almost exclusively determined by the supply of private owners. Rental housing subsidized by the state or municipalities has a very low share. It makes up only 1.5% of the entire housing stock, which is significantly the least among EU countries (Habrman, 2018a).

Price bubbles can also be prevented by faster and better regulation of new constructions. The regulation of new constructions, which inhibit the new property developments in more developed regions, also remain a challenge for the public sector. This leads to a time mismatch between supply and demand and to rising prices. According to the Doing Business index, only 8 countries in the world are worse than Slovakia in this respect. The biggest delays are caused by territorial and construction proceedings. For comparison, the Czech Republic can show a good example in this regard, where territorial and construction proceedings are combined into one process and last 37 days (Habrman, 2018b).

We consider it necessary to adjust the remuneration of financial agents, whose new setting should not allow the possibility of instant earnings but should support professional financial advice. Certain changes in remuneration have recently begun to be implemented, but their systematic and comprehensive application is necessary as part of a macro-prudential policy.

Ultimately, it is necessary to look at credit expansion through the approach of the central bank's policy and government interventions into the principles of market functioning. Our other recommendations are related to raising the national financial literacy standard not only in basic financial and banking terms, but focusing on complex financial decision-making, and areas such as awareness of disproportionate indebtedness, the ability to better assess risk, which we address in a separate study.

Conclusion

The aim of the paper was to verify our postulate by testing the derived hypothesis. At the same time, we anchored the research problem with broader connections using the inductive method. In order to formulate conclusions, we did not necessarily limit ourselves to their diversion into a separate chapter, but we formulated them primarily in the discussion section. Thus, we did not silence the stimulated creativity, let the thought processes flow, allowed the penetration of new postulates, maximized the work with expert literature and thus obtained valuable premises. Our findings ultimately led to solutions and bring concrete proposals for policymakers in Slovakia, as well as other countries in Central and Eastern Europe.

Portfolio Analysis of Real Estate Crypto Tokens and Cryptocurrencies in Mixed Asset Portfolios

David Elferich[1,*]

[1] University of Kosice, Faculty of Economics, Letná 9, 042 00 Košice / Berlin Institute of Finance, Innovation and Digitalization e. V., Badensche Straße 52, 10825 Berlin

Abstract

Research background: In the wake of the last major wave of digital innovation, the highly speculative investment market based on various crypto tokens has been a major factor driving the growth of the financial industry. Bitcoin as the market leading cryptocurrency with a market share of over 40 percent (Coinmarketcap, 2022) takes an increasing market position as a driver for the investment market described above. For this reason, selected cryptocurrencies backed by real assets are used for admixture in the portfolios. Here, selected real estate cryptocurrencies represent both real and investment structures that are easily accessible to all users. The focus of this investigation is the efficient limits of optimal portfolios all portfolio constellations represent, whereby the return can be maximized with respect to the targeted risk.

Purpose of the article: This paper is focused on the analysis of real estate crypto tokens and cryptocurrencies in mixed asset portfolios within the efficient portfolio theory. The research purpose is based on the examination of risk-return ratios for the various constellations of mixed asset portfolios.

Methods: The research approach is to be interpreted as a continuation of the study 'The role of Bitcoin in well diversified portfolios: a comparative global study' by the authors Moro, A. and Kajtazi, A. (2018), with a scientific specification on the analysis of Real Estate Crypto Tokens as a component of mixed asset portfolios.

Findings & Value added: The research results indicate that mixed asset portfolios have beneficial return ratios by including real estate crypto tokens and cryptocurrencies, nevertheless the portfolio constellations have significantly higher risk ratios. Further research results can be stated by referring to the inevitability of Cryptocurrencies market performances, which encourage the financial markets to assign further investment researches.

1 Introduction

The asset class of real estate in mixed portfolios has been one of the main investment focuses of investors worldwide in recent years, as the market has gained interest through the further development of indirect real estate investments in the form of real estate funds, listed real estate shares, Real Estate Investment Trusts, or certificate-based investments. The investment hurdles and risks have been reduced in contrast to direct real estate investment, with the asset class in particular gaining in popularity and being used as a diversification instrument for mixed-asset portfolios. During the last major wave of digital innovations, the highly speculative investment market based on various crypto tokens have been a significant factor in the growth of the financial industry. Bitcoin, as the market-leading cryptocurrency with a market share of over 40 percent (Coinmarketcap, 2022), is taking on an increasingly market position as a driver for the investment market described above. Bitcoin and other popular cryptocurrencies have been subject of research for a couple of years now. Pho et al. (2021) compared Bitcoin and Gold to see which one acts as a better diversifier and concluded that risk-seeking investors looking for higher returns could potentially add Bitcoin to their portfolio. Platanakis and Urquhart (2020) found similar results for risk-adjusted returns in their portfolios. Similarly, Bitcoin has been researched regarding hedging strategies and short selling Bitcoin (Guesmi et al., 2019; Li et al. 2021). Akhtaruzzaman et al. (2020) confirmed Bitcoin as a hedging tool against risk for industry portfolios. This is a similar result to the study by Chemka et al. (2021) where they showed the effectiveness of Bitcoin as a hedging asset in reducing risk in international portfolios. They added, that during the Covid-19 pandemic, Bitcoin cannot provide shelter due to its increased variability. Symitsi and Chalvatzis (2019) concluded that Bitcoin is a significant diversifier when analysing portfolios consisting of currencies, gold, oil and Bitcoin. Especially due to the growing 'acceptance' and 'popularity' of Bitcoin as an asset benefit and simultaneously struggles due to a highly volatile investment increase based on its pioneering position (Nakamoto, 2008). However, the volatility fluctuations of recent years have been too much of a blessing and a curse for Bitcoin, as the following figure shows (Inci, Lagasse, 2019).
Figure 1. Bitcoin's market capitalization during the years 2013 until 2022

Source: Coinmarketcap, 2022

The research focus is on the analysis of risk-return portfolio structures through the admixture of Bitcoin and other crypto assets. The efficient frontier of optimal portfolios includes all portfolio constellations, whereby the return can be maximized with respect to the targeted risk. Here, the selected crypto stocks are added to the optimally diversified portfolios to check their influence on the risk-return structure. An extension to crypto stocks is done for two reasons. First, while the advantage of crypto technology is undisputed, there is still a lack of feasible business models that can be implemented and

understood by users and investors. For this reason, selected cryptocurrencies backed by real assets are used for admixture in the portfolios. The selected real estate crypto assets represent both real and investment structures easily accessible to all users. Thus, the question must be raised: How is the global financial system on the example of the money and asset market, as the central actor, sponsor, and supervisor of the pre-described market developments, affected by these innovative changes? For answering this question, one must refer to the year 2008, a year of historical, fiscal policy dismissal, when a truly disruptive technological development was announced by the publication of a white paper entitled 'Bitcoin: A Peer-to-Peer E-cash System' (Nakamoto, 2008). It was intended to be the starting point for a new type of fiscal policy. In the shadow of the growing progress of central banks' efforts to digitalize the cash-dominated monetary system (Pichler, Summer, Weber, 2020), Bitcoin, and subsequently other crypto-currencies, have shown considerable co-growth progress.
Figure 2. Blockchain process of smart contracts

Source: Abbadi, 2019, p.4

As a result, assets that previously were subject to limits due to illiquidity or legal trading restrictions can become liquid and freely tradable goods. For example, the World Economic Forum in its report 'Deep Shift Technology Tipping Points and Societal Impact' predicts that an estimated 10 percent of global Gross Domestic Product (GDP) will be traded through blockchain applications by 2027 (World Economic Forum, 2015). Especially for the digitization of previously illiquid assets, such as real estate and gold, the process of 'tokenization' enables the value of the entire investment market to increase, allowing buying, selling and trading processes to be carried out in an unlimited and accelerated manner, as the following figure shows in a highly simplified form (Dowsett, Wied, n.d.).

Figure 3. Tokenization of assets through blockchain solutions

Source: Deloitte, 2017, p.19

Various market players worldwide have integrated blockchain applications into their existing systems, as this can be seen in the example of the transaction-rich sectors of the financial market. For example, Exporo, one of the leading crowdfunding platforms for real estate financing, has launched a blockchain-based financing basis for real estate. By implementing the blockchain technology, a 'digital twin' of a property is created, which

makes it possible to reduce the proportionate allocation of share ownership of a property to a fraction of the share ownership that would otherwise be necessary. This allows investors to make diversified investments with minimal investment volumes. At the same time, this process opens up access to otherwise inaccessible forms of investment to a large number of micro to large investors (Exporo, 2020). Thus, corresponding 'tokenized assets' can be promoted and sold in connection with innovative stock exchanges, whereby previously limited investment volumes for particularly illiquid assets can be newly tapped by the financial market (Don, Rajah, Ott, Fromm, 2019). A thorough review of blockchain in the real estate sector highlights, that many blockchain ideas remain empirically unconfirmed. On the other hand, blockchain could increase efficiency, reduce time, and provide verifiability, transparency, and automation in the real estate sector, according to Saari et al. (2022). Additionally, the applications could help reduce fraud, increase security and trust compared to centralized digital solutions (Saari et al., 2022).

2 Portfolio management – research methodology

Portfolio management as the basis of an optimal portfolio is based on rational decisions and helps to close the gap of information uncertainties between business and finance. The concept of the optimal portfolio is based on two fundamental elements of investing: minimization of risk and maximization of the expected return. Investors and their portfolio managers strive to minimize possible price fluctuations while maximizing expected returns. This is done by considering their individual risk tolerance, whereby portfolio 'optimization' heavily depends on the following indicators: variance of the excess return, correlation of returns on assets and Sharpe Ratio. Investors can increase the variance and at the same time the yield of the portfolio by considering uncorrelated or counter-correlated investment values. As shown, positively correlating assets have a negative effect on portfolio variance and negatively correlating assets have a positive effect on portfolio variance (Trautman, Dorman, 2018). It should be noted that the efficient diversification of a portfolio based on these previously described ratios represents the conceptual design of an optimal portfolio and that each investment unit can have an influence on the overall performance of a portfolio. This insight already led Markowitz (1952, 1976) to his groundbreaking work, which continues to form the basis of Modern Portfolio Theory in today's financial systems (Kajtazi, Moro, 2018). In conclusion, Markowitz came to the concepts that an investor based on the Modern Portfolio Theory would have to consider neither the systematic nor the systemic risks – more on this later – but due to the self-regulating diversification of the portfolio, only the systematic risk would be considered relevant. In anticipation of the brief explanation of the risk subdivisions, it should be said that the non-systematic risk, as an asset-specific component, is to be avoided and the systematic, as an overall market-specific risk, cannot be avoided by diversifying the portfolio based on Modern Portfolio Theory, as shown in the figure below (Markowitz, 1952).
Figure 4. Systematic and unsystematic risk

Source: Trautman, Dorman, 2018, p. 13

Markowitz' intention is to reduce unsystematic risk, which at the same time improves the risk-return ratio. Systemic risk, on the other hand, cannot be reduced or avoided and is therefore compensated by a return on an investment. Overall, the depth and breadth of diversification creates a combined portfolio risk-return profile. Relevant to the use of the Mean-Variance Framework as the underlying model of Modern Portfolio Theory, as described in the following part, is the basic assumption of Markowitz (1952) that by calculating the return, standard deviation and correlations, efficient portfolio weighting is possible for portfolio optimization.

3 Mixed asset portfolios – research results

The methodology used is broadly based on Modern Portfolio Theory (Markowitz, 1952, 1976) and on the article "The role of Bitcoin in well-diversified portfolios: a Comparative Global Study" by Kajtazi and Moro, 2018. Here, the methodology is divided into evaluation phases. Existing portfolios are compared to analyse how the addition of Bitcoin and other crypto assets affect risk-return structures. The impact on portfolio risk is mapped, as well as the impact on portfolio return. It should be noted that only portfolio risk in the form of a minimum variance portfolio is defined as the primary objective. The same period from 01.01.2018 to 31.12.2020 is analysed for the studies. The study groups were adopted and analysed for the period from 01/01/2018 to 12/31/2020 in subsequent analysis. To complement the research group of Moro, A. and Kajtazi, A. (2018), additional crypto tokens with a business focus on the real estate industry are attached. Here, a basket of Real Estate Crypto Tokens was studied, which were selected based on the following two databases www.cryptoslate.com/cryptos/real-estate/ and www.coinmarketcap.com. As a result of the previously named real estate crypto stocks, a self-created real estate crypto index was added to the series of investigations.

This consists of the entire basket of the selected real estate crypto stocks, which were shown in the form of a sum function through the one-time inclusion, regardless of their respective price levels. The conducted research approach is not intended to be exhaustive. Individual study values have been selected based on the portfolio structures. In the context of the research, the portfolio structures 'Total Portfolios', 'Mix Portfolios' and 'Two-Pair Portfolios' were examined for their Minimum Variance Portfolios, Naive-Equal-Weighted Portfolios and Maximum Variance Portfolios. These are shown below as an example of the portfolio structure 'Total Portfolios' in the investigation period from 01.01.2018 to 31.12.2020.

Table 1. Portfolio Variance – example – 'Total Portfolios' 01.01.2018 until 31.12.2020

Portfolio Assets	Minimum Variance	Naïve equal weights	Maximum Variance
Portfolio Return	10.90%	-2.49%	-20.78%
Portfolio Variance	3.547%	192.21%	36663.16%
Portfolio Volatility	18.83%	138.64%	1914.76%
R(f)	0.173%	0.173%	0.173%
Sharpe Ratio	0.56	-0.01	-0.01
Slope	0.579	-0.018	-0.011

Source: author's research

In the further evaluation process, in addition to the presented Variance-Portfolio evaluations, corresponding Efficient Frontiers were also examined. These are based on the portfolio structures of the 'Two-Pair-Portfolios', each shown at the reference value 'BTC-USD-Index' and the further examination values. In the following, the imputed evaluation of

the 'Two-Pair-Portfolio' for the examination value 'BTC-USD-Index' and the 'Crypto-RE-Index' for the period 01.01.2018 to 31.12.2020 is shown as an example.

Table 2. Portfolio analytics – efficient frontier – calculation – 'Two-Pair-Portfolio'

Series final – Efficient Frontier Portfolios (01.01.2018-31.12.2020)			
Weights		Analytics	
BTC USD Index	Crypto RE Index	Annual Return	Annual Standard Deviation
100%	0%	36.02%	44.89%
90%	10%	26.18%	405.05%
80%	20%	16.34%	1498.91%
70%	30%	6.51%	3326.46%
60%	40%	-3.33%	5887.75%
50%	50%	-13.16%	9182.72%
40%	60%	-23%	13211.40%
30%	70%	-32.84%	17973.79%

Figure 6. Portfolio analytics – efficient frontier – S&P 100 vs. BTC USD Index

Source: author's research

The collected data models were summarized for further analysis as part of the inductive study and structured according to the three study periods (01/01/2018 - 12/31/2018, 01/01/2019 - 12/31/2019, and 01/01/2020 - 12/31/2020).

4 Conclusion

Accordingly, the researchers Symitsi and Chalvatzis (2019), Shahzad et al. (2019) and finally by Shahzad et al. (2019) demonstrated the beneficial admixture of Bitcoin to mixed-asset-portfolio for enhancing the risk-return performance. However, it should be noted that under extreme market conditions, Bitcoin can be considered a rather weak hedging instrument, which leads to the scientific assumption that further research based on the novel data base is necessary, especially in times of the recent economic financial crash of the global financial markets due to the COVID-19 pandemic (OECD, 2020). This finding of the preliminary research conclusion could be supported by the empirical elaboration according to which a highly significant improvement of the 'risk-return efficiency' is achieved by adding the 'BTC-USD index' to the selected 'mixed asset portfolio'. This is on the one hand due to the improved 'Sharpe Ratios' and on the other hand due to the highly significant correlation evaluations of the return values (Return) when considering the 'Naive equal weights portfolio'. In addition, however, the non-existent correlation between the study value 'BTC-USD Index' and the 'Naive equal weights Portfolio' based on the correlation evaluation of the volatility values (Risk) must be considered, according to which the study value 'BTC-USD Index' shows a significantly higher volatility on average compared to all three portfolio constellations 'Minimum Variance Portfolio', 'Naive equal weights Portfolio' and 'Maximum Variance Portfolio'.

A final remark is listed below, according to which Bitcoin and other cryptocurrencies were already attributed a far-reaching significance in 2015 according to the report 'Deep Shift Technology Tipping Points and Societal Impact' (World Economic Forum, 2015). Following this approach, the World Economic Forum published a far-reaching statement in 2020 as part of the 'Great Reset' (World Economic Forum, 2021). Accordingly, the assigned Global Future Council on Cryptocurrencies stated in 2020 that "Cryptocurrencies have reached a point of inevitability." (World Economic Forum, 2020). A statement, which will be followed in the context of this thesis. Accordingly, the presented research results contribute to the scientific debate on the relevance of cryptocurrencies. A continuation of the research approaches can be advocated and represents the basis for achieving far-reaching research validity.

Abstract

Research background:
The global financial system is on the example of the money and asset market, as the central actor, sponsor and supervisor of the pre-described market developments, affected by innovative changes? For answering this question one has to refer to the year 2008, a year of historical, fiscal policy dismissal, when a truly disruptive technological development was announced by the publication of a white paper entitled 'Bitcoin: A Peer-to-Peer E-cash System' (Gurria, 2008). It was intended to be the starting point for a new type of fiscal policy. In the shadow of the growing progress of central banks' efforts to digitalize the cash-dominated monetary system (Weber, 2020), Bitcoin in particular has shown considerable co-growth progress.

Purpose of the article: The aim of this paper is to analyse the Bitcoin's invention and the impact on the financial markets. Thus, the question has to be raised: how is the global financial system on the example of the money and asset market, as the central actor, sponsor and supervisor of the pre-described market developments, affected by these innovative changes?

Methods: The research method is based on the invention and market analyses of Bitcoin in the financial markets, among other things, since the Global Future Council on Cryptocurrencies stated that Cryptocurrencies have reached a point of inevitability. (World Economic Forum, 2020).

Findings & Value added: According to the World Economic Forum's Global Future Council on Cryptocurrencies the international bodies have been working on assessing risks and appropriate policy responses to the rise of cryptos. Globally, central banks and regulators already have their eyes on this growing trend. (World Economic Forum, 2022).

1 Introduction – Bitcoin's invention

A brief historical digression at the beginning of this work: in the 14th century the Bardi family had a very powerful and prosperous position. Their fields of work included both trade and banking, at that time they ran one of the largest banks of the late Middle Ages and together with the Peruzzi family they were among those who subsidized the war activities of King Edward III against France. In the historic year 1345, when England went bankrupt and the families were not reimbursed for their war payments, they were forced out of their initial businesses. In the same year, the Bardi family, who had almost completely lost their fortunes, decided to change their business: from banking to precious metals mining. However, due to their lack of expertise, they were caught at the very beginning of their new venture and sentenced on 15 October 1345. Interestingly, the main reason for their failure as a mining company was their lack of liquidity and the appreciation of the gold price. The latter in particular marked the historical years between 1333 and 1348, when the epidemic spread of the plague completely changed the social and economic fabric throughout Europe (Kajtazi, Moro, 2018).

In the course of history it can be seen, as the American writer Mark Twain already stated „history doesn't repeat itself; it rhymes", that 'allegedly' constant market structures and their leading market actors are over time constantly forced to make radical economic adjustments due to either socio-political events, technological innovations or recurrent collapses due to epidemic incidents. In recent times since the 1990s, a transformation of the predominant industrialized markets, caused by the progressive globalization and increasing technological disruption, can be observed. The wave of technological inventions in the late 20th century led to a new conception of a modern, sociological and economic market structure, shown by the example of the telecommunication sector in figure 1.
Figure 1. The Evolution of Telecommunications.

Source: M-STAT, (n.d.)

Following this trend, in the 21st century technological developments are still predominant for market changes and are increasingly taking oligopolistic or already monopolistic market structures. For example, the inventions of digital social networks have redefined 'human' interaction, reformulated the idea of 'connectivity' and changed the way people exchange information. The smartphone and its application technologies have provided billions of people with an astonishing array of information and direct access to novel network structures. Each continuation of the Internet's improvement has fundamentally affected the structure of social and economic systems by intensively changing existing assumptions about the need for the physical exchange of information, goods and services.

As already mentioned, technological developments have continued to develop with exponential growth, particularly in the past 25 years, and have almost completely reached all sectors of the economy (Burniske, 2017). Thus, the question has to be raised: how is the global financial system on the example of the money and asset market, as the central actor, sponsor and supervisor of the pre-described market developments, affected by these nowadays innovative changes? For answering this question one has to refer to the year 2008, a year of historical, fiscal policy dismissal, when a truly disruptive technological development was announced by the publication of a white paper entitled 'Bitcoin: A Peer-to-Peer E-cash System' (Gurria, 2008). It was intended to be the starting point for a new type of fiscal policy. In the shadow of the growing progress of central banks' efforts to digitalize the cash-dominated monetary system (Weber, 2020), Bitcoin in particular, and subsequently other crypto-currencies, have shown considerable co-growth progress.

3 Bitcoin a growing investment market – research methodology

The variety of existing crypto-currencies consists of two main categories of blockchains, according to which a division into permission-free and permission-conditioned blockchains is to be made. Permission-free blockchains are based on a public data structure and permission-conditioned blockchains work on the basis of a 'fault-tolerant' protocol, as explained below (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). For an overview, the following figure shows the three layers of the permission-free blockchain and the interconnections of the layers.
Figure 2. Structure of permissionless blockchains.

Source: Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019, p.2

At the application level, transactions are used by the end users. They have an identity which is defined by their individual 'public key' and their secure 'private key'. By combining the two elements, the application layer enables the end user to generate transactions that reach so-called 'mining nodes' via a 'client library' which are directed to the consensus level. The transactions generated can include simple currency exchange or commodity transactions. (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). The consensus layer represents the 'mining' process, whereby the transactions received are checked at the 'mining nodes' by the 'miners' trying to solve a 'cryptographic puzzle'. The miner who solves the 'puzzle' sends the transaction in a block to all 'nodes' so that further miners check the 'solved puzzle' and declare it valid. Subsequently, the transaction is released and irrevocably added to the existing 'chain' in the form of the block (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). The storage layer represents the 'general ledger' of all resolved, checked and released transactions, after which a tamper-proof blockchain is created, which in turn is managed by each 'mining node'. The storage layer is based on a distributed general ledger, which is managed by a public 'node network'.

The inner life of the general ledger thus consists of 'blocks' lined up next to each other, which in turn have stored a series of valid transactions. The 'nodes' are the actors of the 'process',, who act as end users or miners. 'End users' can serve all three levels, the 'miner' has to serve the consensus and storage layers (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). As an introduction, the following illustration shows the three layers of the permission-related blockchain.
Figure 3. Structure of permissioned blockchains.

Source: Zakhary, Amiri, Maiyya, Agrawal, Abbadi,2019, p.5

The application layer of a permission-driven blockchain is structured similarly to the previously described structure of a permission-free blockchain (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). The consensus level also represents the receipt and validation of transactions based on the known and identified 'nodes'. Therefore, the sometimes costly 'mining' process can be replaced by conventional consensus protocols to ensure verification and release of the transactions (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019). The storage level of the permission-based blockchain, on the other hand, is again similar to the permission-free blockchain and is based on a distributed 'general ledger', which can be managed by all nodes of a blockchain (Zakhary, Amiri, Maiyya, Agrawal, Abbadi, 2019).

Research methodology is focused on the basis of an optimal portfolio theory, which offers information to close a gap of information uncertainties between business and finance parties in the markets. The concept of the optimal portfolio is based on two fundamental elements of investing: minimization of risk and maximization of the expected return. Investors and their portfolio managers strive to minimize possible price fluctuations while maximizing expected returns. This is done by considering their individual risk tolerance, whereby portfolio 'optimization' heavily depends on the following indicators: variance of the excess return, correlation of returns on assets and Sharpe Ratio. Investors can increase the variance and at the same time the yield of the portfolio by considering uncorrelated or counter-correlated investment values. As shown, positively correlating assets have a negative effect on portfolio variance and negatively correlating assets have a positive effect on portfolio variance (Trautman, Dorman, 2018). The collected research results are presented within the following subchapter according to the structure of the question.

4 Bitcoin replaces traditional and alternative assets – research results

Irrespectively of the underlying blockchain technology, the global financial investment market is undergoing a process of change. Especially since the times of global economic crises such as in 2001, 2008 and 2020, well-structured 'alternative' diversification instruments show an improvement in the risk-return ratios. Greer provides the following breakdown, as shown in the figure.

Tab. 1. Categorization of traditional and alternative assets

	CAPITAL ASSETS "Ongoing source of something of value…valued on the basis of net present value of its expected returns."	CONSUMABLE/ TRANSFORMABLE ASSETS "You can consume it. You can transform it into another asset. It has economic value. But it does not yield an ongoing stream of value."	STORE OF VALUE ASSETS "Cannot be consumed; nor can it generate income. Nevertheless, it has value; it is a store of value asset."
EQUITIES	X		
BONDS	X		
INCOME-PRODUCING REAL ESTATE	X		
PHYSICAL COMMODITIES (e.g., grains or energy products)		X	
PRECIOUS METALS (e.g., Gold)		X	X

As investments are increasingly driven by an intensive search for returns, 'traditional' asset classes are increasingly being considered less and 'alternative' asset classes primarily more as attractive risk-returns investments (PwC, 2018). This leads to a lower diversification effect of traditional investments. Most of these asset classes are affected by the same macroeconomic variables due to globalization and are no longer limited to individual markets by affecting the entire world economy. This statement, backed up by facts and figures, show that investors have a growing interest for truly new portfolio diversification instruments. In fact, approximately USD 13.9 trillion will be provided by institutional investors for 'alternative' assets in 2020 – from asset classes such as real estate, commodities and gold investments (PwC, 2018). In addition, institutional investors and high net worth individuals have committed more capital than ever before to new investment classes. According to the 2019 Capgemini and Merrill Lynch World Wealth Report 2019, investors have increased their 'alternative' asset share by 4 percent from 11 percent to 13 percent between 2018 and 2019 (Capgemini, 2019).

Gold as one of the supposedly 'most species-like' asset on the research topic 'Bitcoin' will be examined in the following, especially with regard to its characteristics as a diversification instrument compared to traditional assets. For example, as early as 1978, the researcher Greer produced a publication that examined the comparison between gold-deposited 'futures contracts' on equity investments demonstrating a favourable risk-return ratio in the years between 1960 and 1974 by investing in gold (Greer, 1978). Further, Greer (1978) described the yield profiles of 'futures contracts' compared to equities as similar. In their work, they examined the period between 1959 and 2004, with 'futures contracts' showing the same yield results compared to US equities. More recent studies by Conover, Jensen, Johnson and Mercer (2010), among others, found that the addition of gold-backed 'futures contracts' to pure equity portfolios achieves efficient portfolio allocation. In fact, Bitcoin and gold have a species-like structure, which means, for example, that stocks are limited and that production and extraction costs are high. Both asset classes currently have a dual function as both a 'currency' and a 'store of value', whereby gold can also have the function of a 'production factor' in the industry and has an intrinsic value. Thus, the gold price can retain its 'intrinsic' value in isolation from a decline in the demand for money by industrial demand, which is why the volatile fluctuations on a theoretical basis should be

less than for Bitcoin (Krause, Pham, 2017). The researcher Dyhrberg (2016) investigated these correlations further and proved in his study that Bitcoin reacts similar to gold. Thus, both asset classes have the theoretical ability to act as risk hedges for systematic market risks. However, especially due to Bitcoin's faster transaction and reaction capability, the intervals of systematic market risk changes can be absorbed more intensively. This does not mean that Bitcoin can be used advantageously as a diversification tool for short-term portfolio corrections. Thus, the study also showed that, using the example of the UK financial market, Bitcoin can act as a significant hedge and substitute for gold (Dyhrberg, 2016).

Pho et al. (2021) researched if Bitcoin or Gold is a better portfolio diversifier. They concluded that Gold is better for risk-averse investors, but Bitcoin can be a better choice for risk-seeking investors looking for potential higher returns. Another study (Platanakis & Urquhart, 2020) found similar results in regards to risk-adjusted returns. Chemkha et al. (2021) concluded that Bitcoin reduces the risk of international portfolios. According to Akhtaruzzaman et al. (2020) an investment in Bitcoin in an industry portfolio hedges the risk against the named portfolio. Symitsi & Chalvatzis (2019) concluded Bitcoin as a significant diversifier when analysing portfolios including currencies, gold, oil and stocks. They added that the decrease of overall portfolio risk is due to the low correlation of Bitcoin with other assets and is not offset by high volatility. Additionally, Guesmi et al. (2019) show that hedging strategies involving gold, oil, equities and Bitcoin reduce a portfolios' risk considerably, when compared to a portfolio made up of gold, oil and equities only. This applies, when a short position in the Bitcoin market is included and is also confirmed by Li et al. (2021).

The study focus is on the sample assets 'BTC-USD Index', 'S&P WCI GOLD (ER)', 'S&P WCI' and 'Dow Jones U.S. Real Estate Index', which are listed as alternative study assets according to the investment classifications.

Table 2. Bitcoin and alternative assets – Inductive 01.01.2018 – 31.12.2020

Periods	Analytics (discret)	BTC-USD-Index	S&P WCI GOLD (ER)	S&P WCI	Dow Jones U.S. Real Estate Index
2018	Annual Return	-72.95 %	-2.90%	-16.06%	-7.41%
	Annual Standard Deviation	69.66%	11.07%	21.11%	18.38%
	Sharpe Ratio	-0.007	-0.017	-0.010	-0.011
2019	Annual Return	94.51%	14.69%	14.90%	26.74%
	Annual Standard Deviation	57.02%	12.45%	24.43%	14.12%
	Sharpe Ratio	0.001	-0.009	0.002	-0.006
2020	Annual Return	301.32%	22.42%	-10.71%	-7.46%
	Annual Standard Deviation	71.96%	24.26%	41.33%	49.78%
	Sharpe Ratio	0.009	-0.003	-0.001	-0.003

Source: author's research

In the study periods 01.01.2018 - 31.12.2018 and 01.01.2020 to 31.12.2020, it can be seen that the sample value 'BTC-USD-Index' has the most advantageous 'Sharpe Ratio'. In addition to the correlation studies, Bitcoin also has a 'mining' terminology compared to gold, which is close to gold mining (Conover, Jensen, Johnson, Mercer, 2010). Here, both 'mining processes' can be significantly differentiated, according to which the risks in gold mining are particularly the volatility of production costs due to the need for constant exploration of new gold production volumes (Krause, Pham, 2017).

By contrast, Bitcoin production is determined on the basis of the prevailing regional energy costs, as the production volume does not only have to be explored as it is the case for gold explorations. Regardless of the production costs, the possible total production of Bitcoin as well as gold is known. While the assumptions for gold are subject to estimation, in the case of Bitcoin an exact specification is possible (Gurria, 2008). Thus, either 'mining processes' either are more intensive or less intensive in phases compared to the two asset classes. Bitcoin mining, on the other hand, will never be completely interrupted, as the Bitcoin protocol contains a mechanism whereby a minimum quantity is produced on a permanent basis, regardless of the supply-demand constellation (Krause, Pham, 2017).

Thus, the hypothesis that Bitcoin is strongly correlated with alternative investments and will replace gold as a 'store of value' in the future can only be partially confirmed, according to which Bitcoin, although having a clear analogy to the asset class of gold, appears unsuitable for a 'store of value' due to the currently still prevailing volatile price formation (Kajtazi, Moro, 2018). However, as early as 2018, the researcher Fry demonstrates the long-term potential of Bitcoin as a 'value store', after which he finds that the volatile properties of Bitcoin compared to gold are declining over a six-year period until 2017, but, as researchers Bouri et al. (2017) also concluded, this was a consequence of the lower trading volume of Bitcoin. This finding suggests that Bitcoin may approach its function as a 'store of value' over time by decreasing volatility.

5 Conclusion – Bitcoin's impact on the financial system

Since then, Bitcoin has taken a leading position as a cryptographic 'currency', followed by currently more than 5,500 other 'currencies'. The market is dominated by Bitcoin having a market share of around 50 percent Bitcoin and the top four players, Bitcoin, Ethereum, Tether and the top 5 crypto-coins, making up over 80 percent of the entire crypto-currency market (Coinmarketcap, 2022). The crypto-currencies are differentiated by their transaction speeds and underlying application areas. Even though most crypto-currencies were not originally invented with the intention of acting as fixed assets, the majority of investors refer to exactly this function. In particular, the invention of crypto-currencies during a period of financial instability (Gurria, 2008) has led to the inclusion of crypto-currencies in investment portfolios for crisis protection and diversification.
Figure 4. Bitcoin's market capitalization during the years 2013 until 2022

Source: Coinmarketcap, 2022

The core challenges here lie in the volatility of the market and the still unresolved, uniform classification of the individual crypto-currencies. For example, the Commodity Futures Trading Commission (CFTC) has commented that crypto-currencies are a commodity, while the Internal Revenue Service (IRS) has classified crypto-currencies as property and the US Securities and Exchange Commission (SEC) has issued a definition that requires a case-by-case decision (Trautman, Dormann, 2018). In this context, the term 'crypto-currency' leads to regulatory ambiguities, as the term 'currency' itself is an allocation to the asset class of the means of exchange and traditional investment. On the other hand, the technical conception and financial use leads to a contrary allocation as 'value store' and thus to the selection of alternative investments. Consequently, the discussions that have repeatedly flared up in recent years about the definitions of 'crypto-currency' or 'digital gold' (Trautman, Dormann, 2018) must be interpreted in such a way that crypto-currencies can be counted among the largest unregulated markets in the world Foley et al. (2019). The core of any attempt for classification is based on the interpretation of the individual purpose of use and the underlying technology. In line with the scientific research orientation, the empirical evaluations produced do not claim to be exhaustive and are intended to make a scientific contribution to the collection of data and information. A final remark is listed below, according to which the crypto value Bitcoin and other cryptocurrencies were already attributed a far-reaching significance in 2015 according to the report 'Deep Shift Technology Tipping Points and Societal Impact' (World Economic Forum, 2015). Following this approach, the World Economic Forum (World Economic Forum, 2021) published a far-reaching statement through the Global Future Council on Cryptocurrencies, according to which it could be stated that: „Cryptocurrencies have reached a point of inevitability (World Economic Forum, 2020). However, the approaching regulatory intent is pervasive, after which the World Economic Forum published the complementary statement: „According to the World Economic Forum's Global Future Council on Cryptocurrencies, there has been no internationally coordinated regulation of cryptocurrencies — though international bodies have been working on assessing risks and appropriate policy responses to the rise of cryptos. Globally, central banks and regulators already have their eyes on this growing trend." (World Economic Forum, 2022). A scientific statement, which can also be made in the context of this empirical series of investigations with the current state of work consequence and the empirical research results. Consequently, the presented research results represent a contribution to the scientific discourse on the relevance of crypto assets in portfolio structures.

The impact of ICT investments in information systems in developing countries – case study of Africa

Frank Febiri[1,*], *Miloslav* Hub[1], and *Romana* Provaznikova[1]

[1] University of Pardubice, Faculty of Economics and Administration, Studentska 95, 532 10 Pardubice 2, Czech Republic

Abstract

Research background: Since the turn of the 21st century, Sub-Saharan African nations have witnessed a significant economic progress that has been driven by improved governmental and policy reforms, strong agricultural development, increased national and foreign direct investment and improving global commodity prices (ICT Works). However, the widespread adoption of technological advances, such as ICT-enabled infrastructure, is likely to be considered the primary driver for this progress as it has acted as a key enabler for all the other improving factors. This paper will seek to highlight some of the primary opportunities and risks involved in the government and international investments in Information Systems, namely ICT-enabled infrastructure.
Purpose of the article: This paper highlights the importance of government and international investments in Information Systems, with a focus on Information and Communication Technology (ICT), for the economic development of emerging economies, with a focus on Tanzania, Uganda and Ghana.
Methods: This paper reviews past and current ICT enabled investments and their potemtial contribution the African continent. An indepth analyis of the various contributions are examioned.
Findings & Value added: Although there will be many threats to overcome for African nations attempting to implement efficient ICT-enabled infrastructure, it is highly likely that the long-term impacts for the region's economic development will be invaluable

Keywords: *information system; economic impact; eeveloping world; ICT; Africa*

1 Introduction

Although it is acknowledged that ICT is not the only important aspect of the Information System, it is however, an aspect that can be analysed in a systematic and coherent manner.

---

[*] Corresponding author: frank.febiri@student.upce.cz

Furthermore, it is ICT that requires significant government and international investment in order to further bolster economic development. The additional features of the Information System can be addressed through implementing other political and cultural approaches but are by no means less important to the overall success of Information Systems. It can be concluded that investments in ICT are also directly or indirectly investments in the overall Information System. This paper will then highlight the importance of ICT and Information Systems for the economic development in Africa. It is also important to note the previous and current challenges faced by many African nations in adopting widespread access to ICT-enabled infrastructure and how these challenges will likely be addressed. One of the primary issues that many of the developing world are confronted with is what is known as 'achieving critical mass' – which is the widespread use of ICT-enabled devices. This paper will explore this issue in more detail. After highlighting some potential ICT related risks that threaten to hinder economic development rather than bolster it, this paper will conclude that, despite the many risks and challenges posed by ICT, the government and international investment in ICT and Information Systems are absolutely essential for the economic development of African nations. Although it is frequently unwise to apply the same conclusions to other regions without a focused analysis of them, it is reasonable to suggest that investments in ICT-enabled infrastructure will be vital in the progress of all developing economies for years to come.

1.1 What are Information Systems?

Arguably, the most important aspect of modern Information Systems (IS) is Information and Communication Technology (ICT) such as computers, databases, hardware, network infrastructure and mobile devices that enable the processing, storing and sharing of information electronically (Caprar et al., 2022). However, ICT is not the only aspect of the IS. There are also human, social and organisational aspects of the IS that play their own vital roles in the functioning of these systems. For example, the most advanced software is worth nothing if it cannot be widely adopted by the human end-user and therefore, the human element of the Information System is vital. Despite this acknowledgment, it is understood that investments in the improvement, management and continuation of IS in the public sector would almost certainly be found to be primarily focused on ICT. This is due to the fact that the research, development and deployment of ICT-enabled infrastructures requires a significant amount of investment. ICT-enabled infrastructure refers to the entire system that must be in place for a society to become digitally enabled. This includes a reliable network of telecommunication cables and satellites, the availability of affordable and user-friendly personal devices, efficient software that is continuously upgraded and updated, and many more.

1.2 Why is ICT such an important aspect of the Information System?

It cannot be denied that ICT-enabled services have played a key role in the development of modern economies (Nasab & Aghaei, 2009). Although some early studies in the late 1980s and early 1990s found that ICT had a limited impact on economic growth (Johnson, 2021), the advantages are now clear enough that many have suggested that ICT is a necessity for advancing an economy. A national ICT-enabled infrastructure allows a nation to connect with each other as well as the rest of the world on a level that would have been impossible to achieve without it.

Considering that in 2014, the ICT sector accounted for roughly 25% of global business expenditure, with this expected to grow exponentially considering that it is recognised that for every job created in the high-tech industry another five are created in other supporting

sectors (European Commission, 2017). A World Economic Forum study identified five of the most common economic impacts of ICT (WE Forum, 2013). It was identified that, on average, a 10% increase in broadband penetration accounts for a 1.4% increase in GDP growth in emerging markets, whilst the Internet itself can account for up to 3.4% of overall GDP. However, although this may be difficult to prove inconclusively, there is a widespread agreement that connection to the Internet is almost certain to have a strong positive impact on the performance of a national economy (Vives, 2017).

The direct impacts of ICT-enabled infrastructure are multi-dimensional and highly complex. For example, the availability of public services online has significantly improved accessibility to the rural portions of society that would otherwise be completely disconnected. This adoption of public digital services can be referred to as e-Government and is considered almost indispensable (Johnson, 2021). In the first quarter of 2020, more than 45 million visits to US government sources were recorded and this number is predicted to rise and will likely be reflected across the world (Johnson, 2021). However, Africa has been ranked as the region with the lowest e-Government services. Additionally, new 'microwork' platforms allow businesses to outsource many individual tasks to contractors based in emerging economies that provide businesses with cheaper yet comparative services. As more citizens in developing nations are able to access personal devices with reliable connections, they are able to access many more employment opportunities that would have never been available without ICT.

This increase in accessible offshoring and outsourcing contractors allows businesses to prosper whilst individuals are able to increase their household incomes. Both of these factors are mutually beneficial. Additionally, it was found that in OECD countries, more that 95% of businesses have an online presence that exploit social media platforms as invaluable marketing tools that allow businesses to reach a much larger and a sometimes-international customer base. With all this considered, it is reasonable to suggest that the developed economies of the 21st century are entirely reliant on reliable telecommunications networks and Internet connections. However, many developing nations are still working on developing their own domestic ICT-enabled infrastructure in order to compete in the modern economy and to promote their own economic development. In support of this necessity, the World Bank and other international organisations have funded numerous ICT-focused international projects that aim to provide the developing world with the assistance it requires to develop a reliable and essential ICT-enabled infrastructure.

2 Methods

This paper reviews past and current ICT enabled investments and their potemtial contribution the African continent. An indepth analyis of the various contributions are examioned.

3 Results

3.1 Current e-Government Projects

The World Bank funds numerous projects all over the developing world that aim to develop and deploy e-Government initiatives with a distinct focus on encouraging economic development through technological advances. "These projects aim to use technology to uplift living standards and propel the country forward" (The World Bank).

This section will focus on some of the most recent projects that have been adopted in African nations such as Tanzania and Ghana. The 'Digital Tanzania Project' is a $150

million project that aims to increase access to broadband for the public and private sector, as well as for the general population (The World Bank). Although Tanzania has experienced some periods of rapid urbanisation, it has been reported that up to 70% of the population still resides in rural areas, of which most of the poorest citizens are usually found. As this paper will explain, it is arguably the poorest citizens of the rural areas that are less likely to have access to ICT-enabled devices or services even though these populations are likely to benefit the most from them. Tanzania is no exception when observing the economic progress of the African continent, however, there exist some regional challenges that may hinder the progression towards universal digitalisation. Many potential investors in the national ICT-infrastructure are being deterred from investing as the Tanzanian government are charging relatively high prices for the rights-of-way access to the network when compared to their immediate neighbouring African countries. Furthermore, the generally low levels of income experienced by the majority of Tanzanian citizens in conjunction with the increased competition have forced prices for ICT-enabled devices and services, which has caused service providers to accept quite low marginal revenues. The inability to make reasonable profits further discourages investors in the system. The Digital Tanzanian Project seeks to encourage investments in the Tanzanian digital enterprise and to ensure that the benefits are experienced across the country. The World Bank hopes to achieve these objectives by collaborating with the Tanzanian Government in adopting effective policies and laws that do not threaten the growth of the industry, building upon the digital skills of government institutions and younger generations, encouraging private investments by ensuring that those investments are attractive and fair, and providing the government with support channels in combatting cyber-crime, data protection and privacy concerns.

The Digital Uganda Vision is a framework that aims to unify the Ugandan people through digital empowerment and strong ICT policy direction (Boon et al. 2019). However, as of 2019, Uganda had one of the lowest rates of internet penetration in the region. Furthermore, less than half the Ugandan population own a mobile device compared to 83% in South Africa and 87% in Kenya, whilst only 7% of the rural population have access to a mobile device. It has been identified that the relatively slow adoption of ICT-enabled infrastructure in Uganda is partly to blame on how expensive it is when compared to the average national income. However, in order to tackle this issue with affordability, the Ugandan Broadband Commission attempted to significantly revise prices, but there is still a long way to go. Nevertheless, there are also many other contributing factors that hinder the progress of connectivity in Uganda, such as, it being amongst the least developed countries with a very low GDP per capita.

The 'e-Transform Ghana Project' aims to achieve very similar results to the abovementioned projects in Tanzania and Uganda (World Bank, 2020). However, one of the key enablers that is highlighted as pivotal in the success of the Ghanaian equivalent, is the achievement of critical mass (World Bank, Ghana). Critical mass refers to the widespread accessibility and usability of ICT infrastructures and can be measured by three overarching factors. These are the use of devices at reasonable prices that allow the general public to access them; the deployment of electronic payment systems that facilitate micro-transactions; and enough users able to pay for all these services. Without the critical mass, a nation will struggle to adopt nationwide ICT-enabled services as if only a fraction of the population can access it, there will be a huge reliance on the traditional non-technology based approaches(Chen, W.& Kamal F., 2016) Government investments must focus on achieving critical mass by ensuring that ICT services are affordable and accessible by the majority of the population. However, private investors are also key enablers for the success of achieving critical mass.

In all the cases of Tanzanian, Uganda and Ghana, it is evident that the achievement of critical mass will be a major challenge in the short-medium term as governments seek to address a multitude of difficulties in progressing their own economies. The continuation of national and international investments will be the key drivers for facilitating this mass adoption of ICT-enabled infrastructure which is absolutely essential for the economic progress of these countries.

A macro view of the African continent paints a portrait of rapid growth in the ICT sector. In 2020, estimates in the mobile network coverage reveal that Africa has 88.4% connectivity, 77.4% 3G connectivity, and 44.3% 4G coverage. Between 2017 and 2020, the people using the Internet in Africa increased from 24.8% of the population in 2017 to 28.6% in 2019 (Adeleye and Eboagu, 2019). Access to mobile broadband for every 100 inhabitants in Africa increased from 25.5% to 33.1%. Africa's Internet access through fixed broadband for every 100 inhabitants increased from 0.4% to 0.5% (Enke et al., 2019). The statistics demonstrate an upward trajectory for the ICT sector in Africa. However, the data also highlights the facts that Africa lags most of the other regions (North America, Europe, and Asia) in the rate of penetration, integration and mainstreaming of the ICT sector into core socioeconomic processes.

These macro-trends are driven by the underlying dynamics that shape access to the Internet, computers, and ICT infrastructure in Africa. For example, in 2019, only 14.3% of households on the continent had access to the Internet at home. Around 7.7% of households in Africa had access to a computer at home in 2019 (Mitchell and Siebörger, 2019). Additionally, an estimated 39.6% of the young people aged 15 and 24 years were using the Internet in Africa in 2019 (Adeleye and Eboagu, 2019). The data explains the slow rate of ICT uptake in Africa compared to other rapidly growing economies, such as China and Southeast Asia economies.

When compared to the global average, Africa is lagging in most of the metrics used to indicate ICT growth, penetration, and integration. For example, 14.3% of the population in Africa has access of Internet at home compared to the global average 57.4%. Around 18.6% of the people in African use the Internet compared to the global average of 51.4% (Mitchell and Siebörger, 2019). The African continent also lags in the gender gap in accessing Internet services; 37.1% of the men in Africa have access to the Internet compared to 20.2 per cent of women (Li et al., 2022). The global average is 55.2% of men and 48.3% of women access Internet services. The gender gap in Africa is around 17% whereas the global gender gap is 7% (Adeleye et al., 2021).

The next section will explore the problems with ICT adoption across Africa and why investments in ICT and Information Systems are so important for the national and regional progress.

3.2 The current problem with ICT adoption

Due to the relatively high price of satellite bandwidth, the widespread deployment of the Internet in the developing world was unrealistic and unaffordable. Analysis of the affordability of fixed prices reveals that Africa has some of the highest costs for fixed-broadband prices as a percentage of GNI per capita when compared to other regions. The range within the African continent spans from a cost of under 2% of GNI per capita in Mauritius and Seychelles to more than 100% in Rwanda, Madagascar, Malawi, Niger, and Burundi. Mauritius and Seychelles are the only nations in Africa that have attained the Broadband Commission target for 2025 (David, 2019). A large chunk of nations in Africa provide capped monthly data allowances for entry-level fixed-broadband plans. The advantage of this approach is that providers can offer reduced costs; however, users are limited in their Internet use (Sloniec, 2019). Additionally, more than 50% of the countries

offer fixed-broadband speeds of between 256 Kbit/s and 2Mbit/s, which significantly hamper the utility of Internet access. Analysis reveals that nations in Africa that offer optimal access to high-quality data at competitive prices (close to the Broadband Commission target) have significantly developed ICT infrastructure, penetration, and integration into their economies (Maitland, E.& Sammartino A., 2015; Rietveld, J., & Schilling, M. 2021). On the other hand, the African nations that offer access to broadband (or ICT services and infrastructure) are considerably costly rates face slow or stunted growth in their ICT sectors, penetration in their populations, and integration into their economies (David, 2019).

However, bandwidth has now begun to drop in price and is therefore becoming a much more affordable commodity for the developing world to adopt. Arguably, the adoption of the Internet by the developing world is absolutely vital in ensuring that these economies remain competitive and continue to develop. There is a significant risk that many developed nations that do not invest in improving their information system infrastructures will be left behind. Furthermore, the existence of a single Internet provider in the developing countries meant that there was very limited investments and no competition on prices. However, as has been discussed, some nations are experiencing a lack of interest from investors due to too much competition driving marginal profits down. A system that addresses both of these issues with improving connectivity in the developing world must be adopted. On the one hand, governments must facilitate a market that allows business enterprises to compete for customers by offering better prices, whilst on the other hand, they must also ensure that the ICT-infrastructure industry is a profitable and attractive option for investors. This is another area that is being addressed by global initiatives such as those outlined in the previous section.

3.3 Why Invest in ICT/Information Systems

Although the opportunities for investments in Information Systems in Africa are almost endless, this paper will highlight some of those perceived benefits for the education and health sector. It is recognised that systemic improvements to these public services are almost certain to contribute towards the progress of the African economy. After all, a healthier and well-educated population are more likely to individually contribute towards a successful economy.

In the education sector, the ICT Transforming Education in Africa project aims to enrich the social and human prospects through the use of ICT in education. The strategic objectives of this project are to improve, through the use of ICT, the teaching methods and abilities of teachers in African schools; encourage the development and widespread adoption of ICT by giving students the opportunities to learn on ICT systems; and to ensure that national education programmes are able to become more centralised to encourage systemic improvements.

The most important opportunities for improved ICT in the African healthcare sector directly reflect upon the core challenges experienced across the region. There is a significant shortage of experienced and suitably qualified healthcare workers in Africa – a continent that hosts roughly 25% of the global disease burden (Luo, Y. A, 2022). Improved ICT systems would contribute to an improvement to healthcare education, even spread allocation of healthcare workers and resources, and the essential ongoing semi-automated monitoring and evaluation of the healthcare system. The introduction of effective ICT-enabled infrastructures will foster a better connectivity between households, care providers, healthcare services and policy makers. This improved communication between these parties will likely contribute towards the improvement of morbidity and mortality rates (Jandik T. & Kali R., 2009). Furthermore, the accessibility of public information campaigns through

more ICT-enabled information systems will allow governments to better manage public health issues or preventable diseases.

3.4 The hope and risk of doing it wrongly

Investments in improving information systems on a global scale are presenting global development opportunities that would be otherwise unimaginable (African Union, 2020). However, in order to capitalise on these unprecedented opportunities, nation states must commit towards facilitating an environment that is suitable.

Agenda 2063 is the African framework that seeks to transform Africa into a global powerhouse of the future and of which, investments in information systems is a key enabler (African Union). In support of Agenda 2063, the African Union (AU) published the Digital Transformation Strategy for Africa (2020-2030) that aims to utilise technology and innovation to transform African economies by encouraging African worldwide integration, invigorating domestic economic growth, increase job creation and subsequently improve the socio-economic enjoyment of all African populations (African Union, 2020). Amongst many ambitious yet highly achievable specific objectives, the African Union hopes to facilitate continent-wide digital empowerment to all African citizens by 2030. As of 2020, there were roughly 200 million African citizens without internet access. It has been recognised that access to an internet connection for these 200 million would significantly contribute towards GDP growth and therefore, this ambition to achieve universal connectivity will likely prove to be a significant contribution to the development of African nations.

Without significant coordination efforts between nations and regional organisations such as AUC, ATU and UNECA, it may be very difficult to achieve the digital agenda. Although this threat does not directly relate to the investments in national and regional adoption of the ICT-enabled infrastructure, it does relate to the adoption of Information Systems as a whole. As previously discussed, the human and organisational features of the Information System are key enablers in exploiting the infrastructures in place. However, it is likely that most interested parties recognise the importance of collaboration which will assist in alleviating this risk.

The improved access to digital technologies will almost certainly lead to an increase in cyber-crimes that many African nations may not be equipped to deal with. Therefore, there is a demand for increased international and regional support to ensure that cyber-crime is addressed in the most effective and reasonable manner. As many of the poorest across Africa have had limited access to ICT, once they do gain access there is a high risk that many will not be aware of the new risks to their personal data and capital. The most efficient approach to addressing this risk would be to ensure that people are educated about the risks as well as ensuring that anti-cyber-crime units are adopted by governments who would have previously not needed them. Both of these mitigatory actions will require significant investments to ensure they are achieved effectively.

Perhaps a relatively overlooked risk to increased accessibility to the ICT-enabled infrastructure relates to gender inequality. It has been found that there is a significant difference between women and men's access to mobile and internet devices across Africa. Failure to address this gender gap may result in further gender inequality as more men will have access to the increased opportunities offered by ICT. The most effective approach to mitigate this risk to gender equality may yet to be determined. However, there may be a requirement for government initiatives that offer free or heavily subsidised access to ICT-enabled devices for women. This would also require significant investments but would almost certainly alleviate the risks whilst also proving to facilitate a higher percentage of women able to access the benefits available to them.

Furthermore, there is a risk that if access to ICT-enabled infrastructures is unaffordable for the poorest citizens, then they will be unable to benefit from its widespread adoption. Arguably, the very poorest are likely to benefit the most from newly available resources such as e-Government services as it is these populations that are in most need of improved socio-economic opportunities. If African nations fail to provide access to ICT at an affordable rate, then the rich-poor divide may be exacerbated even further, which may be even more difficult to address at a later stage. The most effective approach to this risk would likely be similar to the approach suggested for the gender inequality risk which would also prove to be costly yet impactful for the regions economic development.

4 Conclusion

Although there will be many threats to overcome for African nations attempting to implement efficient ICT-enabled infrastructure, it is highly likely that the long-term impacts for the region's economic development will be invaluable. Economic development must not only be related to domestic GDP growth as it is important that people's quality of lives also improve concurrently. Significant investments in African Information Systems, such as those from the World Bank and African Union, are absolutely essential in ensuring that the future progress of the African economy is secured. As more people are awarded more access to the Internet, there will be an exponential growth is improvements to education, health and business opportunities that will all contribute towards regional development. It can be reasonably concluded that government and international investments in Information Systems are pivotal in bolstering the developing world's economic growth.

Climate change strategic management adaptation in agriculture in Slovakia

Patrik Fitala[1,*]*, Xénia Szarková*[1]*,* and *Radovan Savov*[1]

[1] Slovak university of Agriculture, Faculty of Economics and Management, Tr. Andreja Hlinku 2, 949 01 Nitra, Slovakia

Abstract

Research background: Climate change is undeniable. Strategic management plays a key role in assessing the right agricultural solutions to climate change problematic. While agriculture is one of the main contributors to climate change, it is also a sector that is highly sensitive to extreme weather events resulting from climate change.
Purpose of the article: This work focuses on studying the impact of climate change on agriculture and evaluating strategic adaptation measures.
Methods: We performed statistical analysis to confirm positive or negative effects of climate change on agricultural wheat yields in Slovakia. Through a provided data from local farmers, we examined the farmer's attitude to climate change, its impacts and clarified his climate change adaptation choices, and finally, through a cost-benefit analysis, we estimated the cost-effectiveness of climate change adaptation measures.
Findings & Value added: The results showed that farmers in Slovakia are currently feeling a positive effect of increased temperatures on their wheat crops but are negatively impacted by the lack of rainfall. We can assume that the need for strategic management, implementation of strategies and their subsequent control are not only an important element of farm management but also long-term prosperity. The cost-benefit analysis showed that three measures in particular, crop rotation, fertilization, and minimal tillage, would have the greatest impact on the cost analysis and overall strategies.

Keywords: *climate change; impact; agriculture; adaptation measures; strategic management*

JEL Classification: *O13; M11; Q54*

1 Introduction

Agriculture is undoubtedly one of the sectors most affected by climate change, but it is also one of the largest sources of greenhouse gas emissions. The main manifestations of climate change include rising temperatures, changes in the intensity and frequency of precipitation, and an increase in the occurrence of extreme weather events. The objective of this thesis is

---

* Corresponding author: xfitala@uniag.sk

to provide an analysis of the impacts of climate change on agriculture, confirming the positive or negative impacts, finding a farmer's perspective, and evaluating the measures as a strategic management approach, especially adaptation measures, necessary to mitigate or adapt to the climate change.

2 Current state of solution of the evaluated issue in the theory

According to the Singh (2021), the factors effecting climate system include natural processes and in the last three centuries were extended by the human activities. As it is mentioned by the US Global Change Research Program (2018), it is important to make a distinction between the terms, climate changes that have a natural origin and climate change, which origin is purely anthropogenic. Županić et al. (2021) stated that the Central European region shows general features of climate change and warming occurs in all areas. According to Slovak hydrometeorological institute (a) over the last 100 years, we have seen a trend of increasing the average annual air temperature by 1,1 degrees Celsius and a decrease in annual total atmospheric precipitation by 5,6% on average. With the upcoming climate changes, the need for strategic measures is high. The Strategic management is the integration of all functions so as to pro-actively manage the total farming system in harmony with the internal and external environment towards achieving the long term goals of the farming business.

2.1 Agriculture in Slovakia

Slovakia is a mountainous country, only 40% of its area is less than 300 m.a.s.l. (Ministry of Agriculture and rural development of Slovak Republic, 2020). According to data from Enviroportal (2021b), the total agricultural land in 2020 was 2 375 025 ha, out of which the largest part was arable land 59,17% and permanent grassland 35,79%. On the other hand, hop gardens had the smallest share of 0,02%, orchards 0,73%, vineyards 1,1% and gardens 3,19%. The key question that economic analysts should answer for decision-makers and investors is whether, when, and how to adapt to the adverse effects of climate change. Han (2017) and Buranatrakul et al. (2018) emphasise that while on the one hand, there are several scientific studies on the physical consequences of climate change, on the other hand, there are still no standardized procedures in which the costs and benefits of adaptation measures ("cost benefit analysis") are assessed against other solutions or maintenance costs of current situation.

2.2 Empirical evidence from current literature

For example, Dunsenge et al. (2018) used an ARDL-linked testing approach, and the results of their study showed a Plant carbon metabolism is impacted by rising CO2 concentrations and temperatures, but also feeds back onto the climate system to help determine the trajectory of future climate change. The link between climate change and economic growth was examined by Malhi et al. (2020) and the study analysed gross domestic product (GDP), precipitation, temperature and arable land as well as impacts on ecosystems. The results showed that there is a unidirectional causal relationship of temperature and arable land to GDP. The strategic management of systems approach was used in a study by Banson et al. (2018) examining the impact of new systems on pork production in Ghana. The results of this study showed a significant positive relationship between new technologies and pork production, with positive and significant short- and long-term relationships between pork production and income. A study by Rehman, Ozturk, and Zhang (2019) examined CO2 emissions and agricultural productivity in Pakistan using an ARDL limit test approach. The

results showed that acreage, energy use, fertilizer use, GDP per capita and water availability were significantly related to CO2 emissions, while improved seed distribution and total grain quantity were negatively related to CO2 emissions in Pakistan. A study by Chandio et al. (2020) examined the impact of global climate change on agricultural production in China. The results show that agricultural production is significantly affected by CO2 emissions in the long-term and short-term analysis, while temperature and precipitation have a negative impact on agricultural production in the long-term.

3 Methods

Our work is focused on assessing the impact of climate change on agriculture, primarily by confirming the relationship between climate change and agricultural yields, by understanding the farmer's view of the impact of climate change on his business, his role, responsibilities, and adaptability, and by the economic evaluation of adaptation changes. The data used in the calculations in the first part of the practical part were obtained from the Slovak hydrogeological institute, focusing on the period from March to September from 1997 to 2019. In the second and third part, we obtained data from 5 local farms situated in East and Centre Slovakia regions. To achieve the goals of our work, we used the following methodology - Descriptive statistics, Unit root test, Correlation analysis, Regression analysis, Guided interview, Net present value and Internal rate of return.

Descriptive statistics- Measures of location (central tendency) - arithmetic mean, median, mode, geometric mean, and quartiles. Measures of variation (dispersion) - range, interquartile range, variance, standard deviation, and coefficient of variation. Measures of shape – skewness and kurtosis used for the test of normality.

Unit root test - One of the tests used for the verification of non-stationarity or stationarity of time series data is the Augmented Dickey-Fuller test (ADF). The decision rule in this testing is following: If the p-value is > 0,05, then we accept the H0 hypothesis, but if p-value is < 0,05, then we reject the H0 and accept H1. The hypothesis set for the ADF test is following:

- H0: There is a unit root in the time-series sample, the data series is non-stationary.
- H1: There isn't a unit root in the time-series sample, the data series is stationary.

Correlation analysis - Correlation analysis provides the information about the relationship between quantitative variables.

Regression analysis - The hypotheses for the multilinear regression are following:

Hypothesis for the model:

- H0: The model is statistically insignificant.
- H1: The model is not statistically insignificant.

The decision rule in this testing is following: If the p-value is > 0,05, then we accept the H0 hypothesis, but if p-value is < 0,05, then we reject the H0 and accept H1.

Hypothesis for the coefficients:

- H0: The coefficients are statistically insignificant.
- H1: The coefficients are not statistically insignificant.

The decision rule in this testing is following: If the p-value is > 0,05, then we accept the H0 hypothesis, but if p-value is < 0,05, then we reject the H0 and accept H1.

Net present value and internal rate of return - Net present value (NPV) is used in the investment planning for the analyzation of the profitability of a projected investment or project.

4 Results

4.1 Data specification

Regarding the data specification, for the analysis of the impact of climate change on yield we used the data from 1997 until 2019 with focus on the period from March to September. In the case of yields, we focused on data on reflecting the hectares yield of wheat in tons. Data of the remaining six variables monitored the climatic condition of the area of East Slovakia during the same period. Specific variables are Yield, Area Temperature, Rain, Wind, Humidity.

4.2 Descriptive statistics

In the first part of our analysis, we focused on the basic data analysis using descriptive statistics for the summarization and description of the characteristics of our data set. The mean value of yields of wheat was 4,664 tons per hectare, and the maximum average temperature was at 21,473 degrees Celsius. According to skewness, that measures the degree of asymmetry, we can conclude that yield, and average rain are positively skewed, while the area, average minimal temperature, average maximum temperature, wind, and humidity are negatively skewed. For the kurtosis, referring to the shape of the distribution, the analysis showed that yield, average maximum temperature, average rain and wind have negative (flat distribution) kurtosis and the area, average minimum temperature and humidity have positive (peaked distribution) kurtosis. Maximum yield of wheat was recorded in 2019 and achieved 6,37 tons per hectare while the minimum 3,03 tons per hectare were recorded in 2003.

The second part of the results considerates the analysis of our data transformed using the natural logarithm. Almost all variables, lnYield, lnArea, lnAverage minimum temperature, lnAverage maximum temperature, lnWind and lnHuminidity are negatively skewed, and only the lnAverage rain is positively skewed. LnYield, lnAverage maximum temperature, lnAverage rain, and lnWind have negative kurtosis, meaning their distribution is flat, while the distribution of lnArea, lnAverage minimum temperature, and lnHuminidity is peaked, having positive kurtosis.

In order to be able to conduct time series analysis, it is firstly necessary to test the stationarity, as non-stationary variable could cause several model-misfunctions. Therefore, we decided to test the data using Augmented Dickey-Fuller test.

4.3 Augmented Dickey-Fuller test

Results of this test show, that almost half of our variables are non-stationary, (yield, area, and average rain) as the value of the test statistics was higher than the critical value at 5% significance level, confirmed by p value that was higher than 0,5. Rest of the variables (average minimum temperature, average maximum temperature, wind, and humidity) are stationary. Due to the fact that not all variables were stationary it was inevitable to use the first difference. Results of variables unit root test at first difference show that all variables are stationary at the level of significance 10%, however, with the critical value at 5% significance level, the variable area was still non-stationary. For that reason, that our data are not stationary and thus we cannot conduct regression analysis, we decided to transform our data using natural logarithm that should ensure that our data will be stationary.

Table 1. Augmented Dickey-Fuller test (ln)

Variables	Test statistics	5% Crit. v.	P-value	Interpretation	10% Crit. V.	Interpretation
lnYield	-4,520	-3,600	0,0014	Stationary	-3,240	Stationary
lnArea	-5,217	-3,600	0,0001	Stationary	-3,240	Stationary
lnAv. min. temp	-4,617	-3,600	0,001	Stationary	-3,240	Stationary
lnAv. max. temp	-5,517	-3,600	0,000	Stationary	-3,240	Stationary
lnAv. rain	-4,144	-3,600	0,0054	Stationary	-3,240	Stationary
lnWind	-3,975	-3,600	0,0095	Stationary	-3,240	Stationary
lnHumidity	-5,360	-3,600	0,000	Stationary	-3,240	Stationary

Source: own processing (2022)

4.4 Correlation

The next step in the analysis of the impact of climate change on yield was calculation of correlation matrix that describes the relationship between two variables, either positive or negative.

The correlation between the lnYield and all other variables is positive, meaning that the variables will always move in the same direction. For instance, when the area of wheat production increases by one hectare, then the hectare yields of wheat will increase by 0,385 tons. However, the correlation between the lnYield and lnAverage minimum temperature, the lnYield and lnAverage maximum temperature, and lnYield and lnWind is very weak. The correlation between the lnYield and all other variables is positive, meaning that the variables will always move in the same direction. For instance, when the area of wheat production increases by one hectare, then the hectare yields of wheat will increase by 0,385 tons. However, the correlation between the lnYield and lnAverage minimum temperature, the lnYield and lnAverage maximum temperature, and lnYield and lnWind is very weak.

Table 2. Correlation

	lnYield	lnArea	lnAv. min. temp	lnAv. max. temp	lnAv. rain	lnWind	lnHumidity
lnYield	1,000	0,385	0,025	0,013	0,188	0,013	0,285
lnArea	0,385	1,000	-0,024	0,040	-0,412	0,380	-0,079
lnAv. min. temp	0,025	-0,024	1,000	0,838	0,269	0,234	-0,374
lnAv. max. temp	0,013	0,040	0,838	1,000	-0,078	0,081	-0,728
lnAv. rain	0,188	-0,412	0,269	-0,078	1,000	0,177	0,363
lnWind	0,013	0,380	0,234	0,081	0,177	1,000	-0,140

lnHumidity	0,285	-0,079	-0,374	-0,728	0,363	-0,140	1,000

4.5 Regression analysis's

For the final part of the analysis of the impact of climate change on yield of wheat we conducted the regression analysis for the estimation of the relationship between a dependent variable, in our case lnYields of wheat, and independent variables. We decided to conduct regression analysis with variables transformed by using natural logarithm, due to the reason that only log transformed variables were stationary. The regression equation that is a result of the regression analysis shows the relationship between each independent variable and the dependant variable. The regression formula with our data is following:

$$lnYield = \beta0 + \beta1lnArea + \beta2lnAv.min.temp + \beta3nAv.max.temp + \beta4lnAv.rain + \beta5lnWind + \beta6lnHumidity + \varepsilon$$

The results of the regression analysis show that 58,9% of the variation of the hectare yield of wheat is explained by the independent variables. Significance F at 0,015 indicates that the model is not statistically insignificant, as we reject the H0 hypothesis and accept H1 hypothesis. Regarding the coefficients, the lnArea, lnAverage minimum temperature, lnAverage maximum temperature, lnAverage rain and lnAverage humidity are all statistically significant. We also rejected the H0 hypothesis and accept H1 hypothesis. Only the coefficient lnWind is statistically insignificant as its p-value 0,758 is higher than 0,05, therefore we do not reject the H0 hypothesis.

4.6 Strategic cost-benefit analysis

Following are the information about the adaptation measures that we decided to evaluate. Regarding the cost, we are mainly focused on implementation cost, of our selected company that would have to incur to implement these practices, and on maintenance costs but we also mention some operational cost that would be related to these changes.

Except the irrigation, that would require an investment equal to 1600 € per hectare, all adaptation practices have relatively low implementation costs, below the 400 € per hectare. For the implementation of mixed cropping the farm would not have to incur any implementation costs.

Regarding the maintenance costs, again the highest costs would be for the maintenance of irrigation system around 550 € per hectare. Medium amount of money would have to be spend on the maintenance of fertilization practises (260 € per hectare). On the other hand, the lowest maintenance cost would be for the crop rotation (25 € per hectare) and mixed cropping (20 € per hectare).

Concerning the operational costs, the cost of application of the fertilizer is approximately 6 € per hectare and the same amount of costs must be spent on spraying. In the case of tillage and the use of deep drilling, the cost per hectare is around 40 € and, last but not least, the mowing cost is around 35 € per hectare. When deciding which adaptation measures to apply while considering the costs, the most beneficial would be the crop rotation, fertilization, and tillage. Crop rotation requires only minimum costs for the implementation and maintenance and results into improved soil quality and decreased incidence of pests and diseases. Fertilization, mainly the use of the fertilization applied specifically on the leaf, can improve the absorbance of nutrients and it also reduces the amount of fertilizer required by half. we present the expected increase in the yield of wheat after adoption of each of the adaptation measures. Except mixed cropping, all adaptation

measures would result in the increase of yields. The most notable increases of 5 and 4 tons per hectare relates to fertilization and tillage, respectively. These two measures were also mentioned in the assessment of costs, as being the most effective.

5 Discussion

The agricultural sector is a large contributor of CO2 emissions. On the other hand, agriculture is severely affected by the changes in temperature, precipitation, soil, and water availability that are a result of changing climate. As it was proved by the results of our practical part, climate change is already influencing the agricultural conditions in Slovakia and is influencing the behaviour of the agricultural business.

Our findings of the impact of climate change on the yields of wheat however do not correspond with the studies carried out by other researchers (Zaied and Zouabi, 2016; Dumrul and Kilicarslan, 2017; Raihan et al., 2021; Chandio et al. 2020). In all the mentioned studies, the researchers confirmed negative impact of increased temperature on various crops or the overall agricultural output. Our finding suggested that if the average maximum temperature increased by one percent, the hectare yield of wheat would increase by 5,884%. On the other hand, Zaied and Zouabi (2016), Dumrul and Kilicaslan (2017), and Raihan et al. (2021), concluded that increase in the precipitation would have positive impact on the agriculture. That was also confirmed by our result, as the regression analysis suggested that a 1% increase of rainfall would lead to increase in yields of wheat by 0,457%. Different conclusions were presented in the study of Chandio et al. (2020). According to their estimations negative impact on agricultural output has not only the increase in temperature, but also increase in precipitation. The study calculated the impact of land area under cereal crops to agricultural output and concluded that a 1% increase in the land area will lead to increase of agricultural output by 1,2774%. Our findings were similar as a 1% increase in the land area will lead to increase of yield of wheat by 0,942%. Ali et al. (2017) in their study focused specifically on the effects of climate change on the major crops including the wheat. Their findings revealed that maximum temperatures have an adverse effect on the wheat production, while the effect of minimum temperatures is positive. Their results also shown that rainfall and relative humidity negatively influence wheat crop yield. All of their conclusions are therefore in direct contradiction to our findings as for instance, increase in precipitation, and increase in humidity would have in our case positive impact on wheat yield. Soryali et al. (2021) confirmed that farmers have very differing beliefs regarding the climate change and the views on their responsibilities towards mitigating and adapting to climate change differ. However, generally, finish farmers seem to have high awareness of climate change and are keen to take necessary actions.

Third part was oriented on the evaluation of costs and benefits of adaptation measures. The findings of Williams et al. (2020) indicated that application of strategic adaptation practices (intercropping, mixed cropping, crop rotation, irrigation, and fertilization) would yield positive results and would be economically profitable, therefore using strategic management approach was needed. According to their evaluation, implementation of irrigation measure would be the most expensive. Overall, only crop rotation and mixed cropping were recommended as the other three practises presented higher risk of failure if adopted due to their longer return. Our results indicated that most beneficial, regarding the costs, would be the application of three practices, crop rotation, fertilization, and tillage. Therefore, we came to the same conclusion with the study of Williams et al. (2020) only in the application of crop rotation. Similarly, in their study was also confirmed the high financial burden connected with construction and maintenance of irrigation system.

Due to the fact, that not all of our conclusions were confirmed by the other studies, we suggest that this thesis might be an inspiration for a much more robust and in-depth research that can be carried out on the larger area in case of evaluation of impact of climate change and on larger sample in case of evaluation of perception of farmers on climate change.

6 Conclusion

To conclude, we were able to achieve our aim. We assessed the overall perception of the agricultural business on the climate change, and more specifically, its point of view regarding the measures that could be applied to mitigate or to adapt to changing climate. And, in the last section, we evaluated costs and benefits resulting from the implementation of each adaptation strategic measure. Our recommendations would be following:

- To create a database that would be centre point for all data related to the climate change and its impact. Regarding the agriculture for instance to have the possibility to find information about the CO_2 from agricultural activities.
- To conduct more comprehensive study, including larger area, that would focus on studying the impact of climate change not only on the yields of wheat but also on the other crops.

There are many studies that examine the impact of climate change on agriculture and while the current effects are not the same for the agriculture around the whole world, it is expected that in the future climate change will lead to the food insecurity. Our work has its limitations, but we believe a that with this part of work we were able to practically and theoretically contribute to positively impact this problematic.

The impact of globalization on the availability and use of telematics data

David Fořt[1], and *Miloslav* Hub[1,*]

[1] University of Pardubice, Faculty of Economics and Administration, Studentska 84, 532 10 Pardubice, Czech Republic

Abstract

Research background: "Think globally, compare locally" is a key to success when defining the composition of a car fleet. Fuel consumption (and related emissions) is second most important parameter (after purchase price) when fleet cars are compared, but source data are calculated based on New European Driving Cycle (NEDC) or newer Worldwide harmonized Light Vehicle Test Procedure (WLTP). The difference between the results of NEDC, WLTP and Real Driving Emissions (RDE) is 20 – 40%. With the arrival of plug-in hybrid electric vehicles and the increase of their global market share, the consumption gap even grew.
Purpose of the article: RDE is the right way to minimize the consumption gap and offers better results, but cannot provide custom data for the choice of the objective fleet. None of these models can consider driving behaviour, weather conditions, road gradient, vehicle load, other car driver and local specifics, so such a model needs to be developed.
Methods: For such an objective model, driver habits and local conditions need to be collected based on his standard fleet operation and applied through the evaluative model to new vehicle selection, where these vehicles are rated upon same conditions in real traffic. Data for the valuation model can be collected from telematics black boxes in older fleets and connected cars by new cars.
Findings & Value added: This is an area where data modelling should take place, as it can bring near-realistic results and bring the utilization of fleet operation to the next level.

1 Introduction

Part of decision-making process is evaluation of risks and costs. Globalized world leads us to act based on "best practices" previous decisions made anywhere in the world. These decisions were sometimes made according to global conditions not respecting local influences. "Think globally, act locally" is an indispensable approach in decision making

---

[*] Corresponding author: miloslav.hub@upce.cz

process as local conditions may vary compared to global conditions despite default inputs are identical. Even small local influence may significantly change the results and radically change the final decision. A hidden area where are these principles overlooked is Fleet management (Akkartal and Aras, 2021). Fleet management is an administrative approach that allows companies to organize and coordinate work vehicles with the aim to improve efficiency, reduce costs, and provide compliance with government regulations (Bielli et al., 2011). Costs can be divided info fix and variable.

Fix costs are mainly managed locally as it's taken from local market, respectively from local offers. Vehicles lease or purchase payments, insurance etc. are demanded locally due to local requirements (e.g. vehicle homologation EU/US). Exceptionally are accepted offers from other markets, if global company is able to give an offer. Depreciation, licenses and permits are given by local legislative. Fixed costs are easy to determinate before acquiring the fleet on any time during operation, renewal process.

Variable costs include costs needed to operate the fleet. These costs are less predictable than fixed costs and are dependent on work volume. Main variable costs that should be included are fuel, tolls, accidents, maintenance and repair. All of this category can be affected by route planning, driving behaviour and maintenance planning. Maintenance plan is given globally by the vehicle producer for each model. It is based on mileage, time (eventually engine hours or fuel used) and it's obligatory for vehicles warranty. There isn't much space for optimization as it is given globally and mandatory, just precise planning can lead to better utilization and limited downtime. Tolls are given by local conditions, regardless of operator, state or private, fees are defined for vehicle category and roads and cannot be influenced without changing vehicle type. Only option is to optimize route to ideal ratio toll fee vs. lost time caused by using road without fees. This option is available in most of online navigation application and except trucks does not offer much space for optimization. Repairs costs can be divided into two sections, by the driver at fault and through no fault by the driver. Second option repair are caused by external influences like damages caused by other vehicles or by road traffic, weather, vandalism and other unpredictable causes. Some like damages caused on parked vehicle can be limited by save parking spot, but that is not available anywhere and increase operation costs of vehicle. Accidents and Repairs where the driver is at fault are connected with driving behaviour or generally with carelessness. As mentioned in a study conducted by (Ando et al., 2010) driving behaviour where absolute value of acceleration, deceleration or handling exceed 0.2G (G=0.98m/s2) is evaluated as potentially risky. With higher speeds and increasing absolute value of acceleration repair costs caused by accidents grows. Whatever aggressive driving behaviour causes higher repair costs exact statistics how much the driving behaviour correlates with damage costs in local conditions are not available. Due to this fact only general data enters the decision making process or such costs are ignored. Last but not least in operation costs is fuel. Fuel is the biggest cost in operation. In decision making process fuel costs are derived from official fuel consumption of the vehicle delivered by car producers. These values are set according to global standards, New European Driving Cycle (NEDC) (Dong et al., 2020) or newer Worldwide harmonized Light Vehicle Test Procedure (WLTP) (Park et al., 2021). NEDC and WLTP were created to set up standards to unify driving cycle in which the CO_2 emissions are measured. Same driving cycles are used to set up official fuel consumption by each vehicle. (Kadijk et al., 2016), (Ramos et al., 2018)

New European Driving Cycle is an older driving cycle develop in the 1980s and last updated in 1997 created to estimate the emissions levels and fuel economy. Originally designed to measure emissions and fuel consumption by petrol vehicles, but also used to measure diesel engines. As new engine types were delivered NECD is used to measure hybrid vehicles and battery electric vehicles. NEDC was valid for EU countries 1998-

08/2017 as homologation lab-bench procedure, even it is not valid anymore, vehicles with official fuel consumption estimated according to NEDC are still parts of existing fleets and need to be included in analyses. (Shim et al., 2014)

NEDC test cycle in done on cold vehicle (20-30 °C) and in "laboratory" conditions, generally performed on a roller test bench. NEDC is composed from two driving cycles, Urban Driving Cycle ECE-15 (UDC), which simulates typical driving condition in European cities and Extra-urban driving cycle (EUDC) which simulates more aggressive driving and higher speeds. Both cycles are precisely defined from time, speed and acceleration perspective. NEDC is composed from 4 UDC cycles and one EUDC cycle, see figure 1. Whole cycle last 1180s, where 0-780s is destined for 4 UDC and 780-1180s for EUDC. (Shim et al., 2014)
Figure 1. New European Driving Cycle.

Source: (Pavlovic et al., 2018)

Despite long driving cycle development and updates of NEDC the consumption gap (difference between official fuel consumption and real consumption) increases rapidly (Degraeuwe and Weiss, 2017). According to data collected from self-reporting consumers and fleet operator fuel consumption data increased the consumption gap substantially in the EU, from about 6% in 2001 to almost 40% in 2017. NEDC was not able to reflect the progress in 21st century technology, which was the main reason for such consumption gap increase (Ktistakis et al., 2022) . Therefore in 2017 European Commission introduced Worldwide harmonized Light Vehicle Test Procedure.

2 Methods

WLTP is a global standard for estimating the levels of pollutants, CO_2 emissions and fuel consumption. It is designed to test traditional petrol and diesel cars, any kind of hybrids and electric vehicles also. WLTP as hint it is not just an EU standard, but it is accepted by China, Japan, the United States, India, Canada, New Zealand, Australia and many more. (Klosterman, 2020)

WLTC are not a laboratory tests, for better results is WLTP divided to three categories according to vehicles performance. Each category has different test cycle and vehicles are sort out depending on vehicle power-to-mass ratio (W/kg) (Bouter et al., 2020):

- Class 1 – lower power vehicles with power <= 22 W/kg
- Class 2 – medium power vehicles between 22W/kg and 34W/kg
- Class 3 – high power vehicles with power > 34 W/kg and all OVC-HEVs, NOVC-HEVs and PEVs

2.1 WLTC Class 1

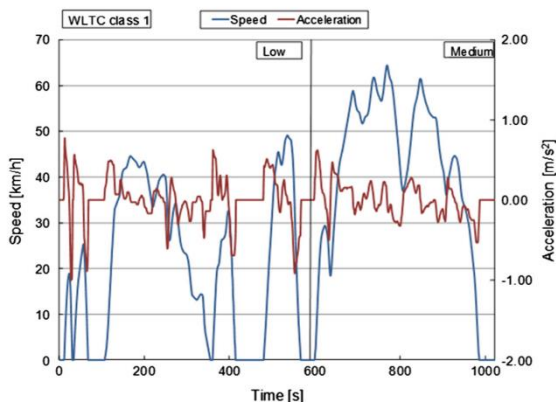
WLTC Class 1 is intended for power vehicles not able to achieve speeds needed for more powered vehicles. Class 1 cycle is composed from low and medium test cycles specific for Class 1, where low least 589s and medium 433s from total 1022s. Compared with NEDC is distance 2875m shorter.


Figure 2. WLTC Class 1 v3.2 Speed and acceleration profiles.

Source: (Tutuianu et al., 2015)

2.2 WLTC Class 2

WLTC Class 2 is intended for medium powered vehicles with power between 22W/kg and 34W/kg. Class 2 test cycle is composed from four cycles, low, medium, high and extra-high with duration 589 s, 433 s, 455 s, 323 s, total 1800 s. Total distance is 22.64 km.
Figure 3. WLTC Class 2 v3.2 Speed and acceleration profiles.

Source: (Tutuianu et al., 2015)

2.3 WLTC Class 3

WLTC Class 3 was proposed for vehicles with power-to- mass over 34 W/kg and for all OVC-HEVs, NOVC-HEVs and PEVs. Test cycle is divided into 4 sub-parts as by Class 2,

low, medium, high and extra-high, but with different course than by Class 2. Total duration is 1800s, distance is 23.27 and high speed is 131.2km/h compared to 123.1km/h by Class 2. (Tutuianu et al., 2015)
Figure 4. WLTC Class 3 v3.2 Speed and acceleration profiles.

Source: (Tutuianu et al., 2015)

WLTC is definitely step forward from global perspective, test cycles are more complex, additional equipment is included and many other. Next to it, it is no more a test in laboratory conditions and with real driving (RDE) part and measurement with portable emission measure system seems that problem with consumption gap, resp. emission gap solved.

3 Results

A Dutch study from 2020 based on data from Travelcard Netherland BV analysing 259,000 petrol passenger cars, of which 33,000 (plug-in) hybrids, 277,000 diesel passenger cars, of which 4,000 (plug-in) hybrids, and 54,000 vans (Merkisz et al., 2020) was found that the introduction of the Worldwide Harmonized Light vehicles Test Procedure (WLTP) reduced the average consumption fuel gap by 20–24% by petrol cars. Converse results were by plug-in hybrids where consumption gap increased to large consumption gap (150-300%), especially by petrol. (Merkisz et al., 2020) These values are valid for Netherlands conditions, where plugin-in hybrids and full electric vehicles are very widespread and completely used. In Czech conditions are results much worse as charging infrastructure is very limited and charging outside home/work needs be more planned. Due to this fact plug-in hybrids are in standard operation used more as petrol vehicles and electric saving estimated in WLTC consumption is not used. That is the main reason for larger consumption gap by PHEV in Czech Republic, see Table 1 PHEV results from 1-8 2022. Source: own study. Even with excellent driving style, which by petrol cars would mean lower fuel consumption values than official fuel consumption, is consumption gap more than 200%.

Table 1. PHEV results from 1-8 2022.

Labels	Mileage (km)	Official fuel consumption	Average of real consumption	Consumption GAP	Driving style with traffic	Driving style
PHEV 1	17436	1.7	4.66	274%	1.35	1.30
PHEV 2	15731	1.3	5.21	401%	2.07	1.55
PHEV 3	10164	1.6	3.68	230%	1.80	1.49
PHEV 4	22168	1.6	9.36	585%	2.23	1.98
PHEV 5	9755	1.2	4.36	363%	2.39	2.35
PHEV 6	13710	1.4	6.85	489%	1.89	1.76

5 Discussion

Petrol and diesel vehicles with official fuel consumption according to WLTC is lower, as mentioned approx. 20-25% by vehicles without focus on driving behaviour and traffic fluency. Driver, resp. driving behaviour, and selecting route, reps. Traffic, affects the consumption gap the most compared to other influences like vehicle factors (vehicle maintenance and aging, rolling and aerodynamics resistance, tires, etc.) or environmental factors (weather conditions, ambient temperature, cold start, road grade, etc.). At Picture 5 Relation between driving behaviour w/o traffic and consumption gap, analysing 25 vehicles Skoda Octavia 1.6TDI in 8-month time period with average mileage per month above 2 500km, you can see the relation between diving style w/o traffic and consumption gap.

If driving behaviour is worse by approx. 1 point the consumption gap increases by approx. 30%. There is also visible that driving style affects consumption more than traffic situation. Unfortunately, there aren't enough data for full evaluation of the result. The driving style uses 1st version where are only fluency, moderate/aggressive acceleration and deceleration enter the driving behaviour evaluation.
Figure 5. Relation between driving behavior w/o traffic and consumption gap.

Source: Own research

Next version of driving style being developed will include more inputs like road altitude, local speed limits and more. Using new data modelling methods and big telematics data collected from black-boxes installed in fleet cars will new model based on data modelling results bring consistent overview enabling decision based on local conditions and customized upon drivers behaviour and needs. Such decision will better respond to fleet needs, increase utilization and limit unexpected excess expenses.

Globalization and decentralized finance

Katarina Frajtova Michalikova[1,*]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Department of Economics, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: The focus of article is introduction of basic building blocks that forms essential platform or toolset if you will, for implementation of various decentralized finance services, which has become a very popular investment for users in recent years. We live in a time when society is changing thanks to technological progress. Technology is advancing in all industries and banking as well finance sector in general is no different. After electronic banking services, which are now an integral part of our lives, decentralized services such as cryptocurrencies, insurance, loans, stock markets and lot of others have been recently introduced to public.
Purpose of the article: With the help of these decentralized services, you carry out various financial transactions practically without waiting, with for very low fees and without need of so-called intermediary institutions that interconnect trading parties. There are already thousands of such services that can be easily utilized in the virtual world.
Methods: Article has been implemented as a result / outcome of various research and analyze procedures focused to map and compare the real world online DeFi services available in the 2022 market.
Findings & Value added: In the article we are focusing to the basics of the decentralized finance services world, its advantages and disadvantages, transactions, wallet as well as most recognized service – cryptocurrencies; vital alternative of the convectional currency as we know it today.

Keywords: *decentralized financing; cryptocurrencies; financing; Bitcoin; Ethereum*

JEL Classification: *M48; G30; F60*

1 Introduction

Decentralized finance banking is generally a term for financial services that take place / are implemented on top of the public blockchain database platforms such as Ethereum, Solana, Decent and others.

---

[*] Corresponding author: katarina.michalikova@fpedas.uniza.sk

This type of financing does not use third parties and requires no paperwork. Through smart contracts, everything is automated, which means that financial intermediaries (e.g. brokers, banks) are not necessary.

Decentralized financing allows any two parties to conduct operations reliably and directly without an intermediary or other external body. More people can access financial services at lower costs or get better interest rates than traditional financial institutions. Although decentralized finance is different from banks, they also provide services such as: earning interest, borrowing, lending, trading assets, buying insurance and trading derivatives (Sarnecký, 2022).

With the help of new technologies, companies and merchants, people can perform financial operations. Using a peer-to-peer financial network (directly between two people, it does not go through a centralized system), they use connectivity, software, hardware improvements cryptography and security protocols. This type does not require access rights for trading in financial instruments, lending or borrowing (Lahuta, 2021).

The use of decentralized financing is relatively simple, as interested parties will acquire a large number of remarkable opportunities in this context, including the creation of smart contracts and their implementation. All you need is an internet connection and you can trade, lend to someone, or borrow through software that tracks and verifies financial transactions in decentralized databases - blockchains. Blockchain decentralized database collects information from all users and is possible to operate in form of millions parallelly running instances located different places that form one uniform and consistent platform (Benson et al., 2021).

With the help of decentralized financing, anyone, anywhere can use financial services. In this type of financing, users can control their digital assets with the help of either personal wallets or business services.

2 Methodology

In this section, we focus on the comparison with centralized banking financing.

Centralized finance is generally a term for financial services that are provided by eligible financial institutions such as banks, insurances or similar corporations. For them, the main goal is to achieve the highest possible profit. Contrary to DeFi, this type uses third parties, which help in the movement of money between parties, but each party also charges certain fees for their services.

In a centralized financial system, financial institutions are important intermediaries that control and mediate financial transactions. Intermediaries try to reduce transaction costs and ensure that financial transactions are mediated efficiently and smoothly (Chen and Bellavitis, 2020).

Through a central exchange, trade orders are processed in centralized funding. Funds are processed on a central exchange, meaning you don't own your let's say key to access your wallet. The central exchange determines how much fees you have to pay for trading and what coins you can trade. In the end, you are not the owner of your finance when buying or selling thanks to a centralized exchange. The exchange sets the rules for you to trade according to.

Unlike an OTC market that allows direct trading between two agents, an exchange is an institution that standardizes assets and trading rules for multiple participants. Therefore, the stock exchange provides mechanisms to maintain asset liquidity and to determine asset prices (Mohan, 2022).

With such centralized approach however comes also various risks and disadvantages. Global world finance system has been disrupted and faced a growing disappointment as well as massive loss of reliability in relation to their customers. These events led various

inventors to idea, whether banking, investing and payment processing could become decentralized and disintermediated. A wide range of new innovations in financial products and services has experienced rapid growth (Allen et al., 2022).

Decentralized financing differs in, that the field of cryptocurrency financial products, they try to maintain the typical characteristics of cryptocurrencies in contrast to centralized financing. They are mainly:

1. Trust in centralized financing, you must trust exchanges and centralized assets, you have no other choice. In decentralized financing, you don't have to trust anyone, because your funds are in non-transparent wallets, where no one has access, nor administrators of the certain service. In centralized funding you have to trust the company, while in decentralized funding you have to trust the protocols and especially the technology.

2. Authorization With decentralized financing, if you have a non-administrative crypto wallet, you do not need to register your account, while with centralized financing, user registration must take place and must be subject to KYC (Know your customer) regulations. Registration serves to prevent criminal activities such as compliance with cryptographic regulations and money laundering (Micky, 2022).

3. Public verifiability Each user of decentralized financing can observe and control the implementation of changes to the state of his funds. It may happen that some decentralized finance applications may not be open source, we can verify this on the blockchain in this case, still this aspect is irrelevant. It is about transparency of the basic implementation / communication protocol that gives decentralized financing technologies an unrivalled power to transfer trust.

4. Fees; One of the advantages of decentralized financing are fees, because they are minimal. Whereas centralized fundings have higher fees for platform maintenance, employee salaries and product improvements.

5. Liquidity; In centralized financing projects, the platforms match the orders of buyers and sellers similar to stockbrokers. In DeFi, all trading is done automatically on the blockchain. Instead, the platforms rely on an innovative concept where both sides of the trade are pre-funded by liquidity providers who are motivated to find their funds. Finally, the trading fees are distributed among the liquidity providers.

6. Speed Execution; speed is relatively fast in both CeFi and DeFi, although it depends on each platform individually. Most exchanges can provide near-instant execution for market orders.

7. CeFi customer services is a highly competitive space where every exchange and institution is actively trying to attract customers. Customer care services offered by this sector are trying to be as perfect as possible, they even established dedicated departments, that proactively look after the needs of the customers. In contrast, DeFi networks are independent networks and usually do not come with customer support services although situation is slightly changing doe to the growing competitiveness.

8. User experience Beginners are more inclined to use centralized financial products because they are easier to use and usually have customer service that answers questions. Most of them even provide an education section on their website. And with DeFi, there is in most cases no human customer service.

9. Regulations; The CeFi sector / space is governed by rules and regulations. Policies such as the fight against money laundering and terrorist financing are being enforced. Regulators and observers are concerned about the risks associated with DeFi, as they are easy targets for hackers and lack investor protection.

10. Innovations; There is not much to innovate when it comes to CeFi services. However, since blockchain is still in its early stages with breakthroughs occurring routinely, DeFi

networks are innovating at an exciting rate. This leaves users with more automated benefits.

11. Potential Threats; The key threat associated with CeFi is nightly hacking of exchanges or other institutions. While exchanges and providers often use state-of-the-art security measures to protect themselves, this does not help them when it comes to exchange heists. On the other hand, the biggest enemy of the DeFi system is the network itself. Any error in the source code of the blockchain can put participants' assets at direct risk and cause complete loss of their deposits (Wazirx, 2022).

3 Results

3.1 Advantages and disadvantages of decentralized financing

3.1.1 Advantages

Immutability of data

Data may not be changed or deleted after being saved in the system. The advantage of immutability is the usability of increasing confidence in the system and its data. Users of these accounts are guaranteed that the data is reliable and will remain there as it was uploaded to the system. However, this property does not guarantee that trusted data has been stored in the system, it follows that it has not been manipulated before being stored in the system.

Absence of central authority

The absence of a central authority that manages the operation of the entire system has many advantages:

− The structure of the system is under the supervision of all involved entities.
− The system has greater immunity to cyber attacks.
− It reduces possible risks and costs and increases the speed of operations in transactional contact between individual entities.

Security

Although decentralized financing is free, if the systems they use must make information available to regulatory and supervisory authorities, and the state must guarantee the cyber security of digital processes (Savona, 2022).

Transparency and privacy

High transparency is another advantage of DeFi, where all transactions are publicly visible. However, they do not provide account names or any information about the owners, so as not to violate the privacy of the parties between whom the transaction was sent. The private key serves us precisely to unlock the owner's account, where he has all the information about him.

Horizontal scalability

Vertical scalability is worse, because the constant growth of the volume of transactions and weaker nodes do not meet the requirements for their demands. However, horizontal scalability is very good. The system is more stable and can provide more computing power when there are more nodes in the network.

Autonomous processing

An account can also be created by a device connected to the network and not only by a legal entity (organization, person) (Bagha and Madisetti, 2017). Automation is already carried out in the device and transaction management in general. In modern platforms, it is already possible to program and thus automate transactions in the form of so-called smart contracts (Bagha and Madisetti, 2017).

Connecting entities that do not trust each other

DeFi financing brings together entities that do not trust each other.

Cryptocurrency financing is unique in that it enables a transaction without the involvement of a central authority (bank, auction portal), i.e. a third party. Entities do not have to rely on the trust of another to complete a transaction.

3.1.2 Disadvantages

Vulnerability through smart contracts

Nowadays, there are many cryptocurrency platforms that provide smart contracts. The goal was to program digital contracts between two or more participants connected to the system, but which would not be legally enforceable in the real world. Anyone can deploy the program code to the blockchain, there is a chance for the potential misuse of smart contracts (Bagha and Madisetti, 2017).

Product risk

Less mature funds or newer protocols are not tested and usually have higher returns. There is a significant amount of risk involved in how your income is generated. Unlike a classic bank, there is no regulation or insurance of your money with DeFi.

Privacy

Transparency of transactions is an advantage, but on the other hand, it can be a disadvantage. If the identity of the account owner is known, we can find out a lot of information about him, such as

e.g. account balance, when they spend money, how often and so on. And it is with transparency that a cyber attack can occur.

Availability

A problem can also arise with the availability of nodes, which some owners, for example they can turn off at night. Since there is no central authority, no one guarantees us that the system will work 24/7.

Insurance

Decentralized financing lacks labour insurance. The insurance is intended to protect investors against fraudulent activities or in case of hacking.

Your responsibility

DeFi presents itself as risk-free and hassle-free financing, but it is not responsible for your mistakes. DeFi transfers responsibility from intermediaries to users. If you accidentally lose your funds, no one is responsible but you. As a result, there is a need to create tools in DeFi to prevent human error. With freedom in financing comes responsibility, and many participants are not used to having to take care of themselves, which can lead to losing their funds or being defrauded (Liecher, 2020).

Transactions

With decentralized financing, it is the same as with traditional financing. Users have an electronic wallet created on their account, in which they store funds in cryptocurrencies. When users send money to each other, it's anonymous, no one needs to know about it.

During the transaction, as with traditional financing, the user enters the destination address where he wants to send the money and also enters the amount he wants to send. He then confirms the transaction with his private key assigned to him.

In the next part, a third party enters into the transaction, which confirms the transactions and consists of other users. The reward for users is different for different types of cryptocurrencies. The advantages of cryptocurrency transactions are mainly low fees, speed and transparency. Their speed is a big advantage, mainly because they all take place within one hour. As soon as you enter a transaction, it will be published on the Internet.

Transaction fees are much lower than sending by bank transfer. Huge benefits we register for international transfers. One of the major disadvantages of transactions is non-returnability (if we enter the transaction incorrectly, it will not be returned to us and it is not possible to claim it).

Figure 15. Transactions log example

Source: https://my.fumbi.network/

3.2 Wallets

A crypto-wallet is a device or program that manages public or private keys that are necessary for cryptocurrency transactions, even when the cryptocurrency is not deposited in the wallet. A wallet is also defined as an encrypted long series of random numbers or words (the so-called personal key). All wallets also have a public key, which is mathematically linked to a private key and allows deposits to be accepted. One wallet can accept several keys, i.e. transactions at once.

These wallets are divided into software and hardware. Hardware wallets are physical devices, they look like a USB key, the advantage of these keys is that they work offline and guarantee higher security for the protection of cryptocurrencies. The opposite is software keys that are online, thus also have security risks. The most used wallets are Coinbase.com, Trezor.io, Blockchain.info.

3.3 Blockchain

According to the National Security Agency, blockchain is defined as an infrastructure that enables different distributed software applications to store, access and store data in a way that guarantees data integrity and high availability, as well as confidentiality.

These are data records of a smaller scale, meaning that only basic information about events, messages or transactions arising in the ecosystem of mutually communicating parties (participants) is entered into the blockchain (NBU, 2021) (Mirri, 2019).

Cryptocurrencies are based on blockchains, which allow parties that do not trust each other to agree on the transfer of funds with minimal counterparty risk (Harwick and Caton, 2020).

Blockchain can also be understood as a type of decentralized distributed database, where there is a list of records where blocks are connected to each other. A record is any information that should be kept in the database, e.g. a record of receiving the shipment or a record of the creation of a document (Mirri, 2019).

In order for transactions to be carried out on blockchains, fees expressed in cryptocurrency units of the blockchain must be paid (Metin and Őzturan, 2022).

Blockchain is one type of distributed network. This is the basic technology of cryptocurrencies, where not only money or currency may be stored within the database, but different types of data may be involved in these cases. When entering data into the database from participants, other participants must confirm the correctness of the entered information and it can then be added to the block (Hrabčák, 2019).

Characteristic features of blockchain:

- is based on an agreement – there must be an agreement between the participants, only then can the information be added to the block,
- cryptographic sealing – information cannot be reversed or replaced, therefore it is closed in blocks,
- chronological sequence of information – information, transactions are recorded chronologically in the blockchain,
- it is digital - no paper documentation.

3.4 Cryptocurrency mining

Cryptocurrency mining is a very interesting process by which cryptocurrencies are compared to digital gold. However, for profitable mining it is necessary to create your own hardware just for mining. As a result of mining, this process becomes extremely competitive, but if we want to mine, we need to study how mining works, find out the cost of electricity, which contributes to the calamitous increase in the environmental footprint, and learn how to mine most efficiently. It is for these reasons that customers prefer to buy cryptocurrency and thus avoid difficulties. (JANA et al., 2022).

3.4.1 Mineable cryptocurrencies

The category of minable cryptocurrencies includes all cryptocurrencies that can be mined by the general public. These currencies include Bitcoin, Litecoin and many others (Coinmarketcap, 2022).

Mineable cryptocurrencies also include preloaded cryptocurrencies. Cryptocurrencies that are frontloaded are known because a certain percentage of their entire money supply is frontloaded, meaning that it was mined by the creator of the cryptocurrency itself or by a small group of people. Among them are, for example, FuelCoin, CureCoin and others (Coinmarketcap, 2022).

3.4.2 Non-minable cryptocurrencies

They represent cryptocurrencies that are not mineable by the public. In this case, it can be cryptocurrencies that use a different system than mining or are not intended for the general public. Non-minables include Ripple, BitShares and others (Coinmarketcap, 2022).

Fully preloaded cryptocurrencies also belong to the category of non-minable cryptocurrencies. Fully leveraged cryptocurrencies are cryptocurrencies whose total money supply has been leveraged, such as Ripple or Osmosis.

4 Conclusion

The use of decentralized financing is on track, but still has room for improvement. Decentralized finance will find many new users in the future and will enter everyday life and be a daily part of financing.

Investors who want to invest and thus take risks with their funds should first of all answer the following questions: What should I buy? How much should I buy? When should I buy it? When should I sell it? These questions cannot be answered in the future, as the market fluctuates, which means that sometimes it is up and sometimes down. Investment platforms provide the investor with help and information on when to buy and sell cryptocurrencies. The most used investment platforms include: eToro, FUMBI, Binance, Kriptomat and Coinbase.

Unemployment in Slovakia and its comparison with other V4 countries

Barbora Gabrikova[1,*]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: If there is an imbalance between demand and supply in the labour market, unemployment occurs. Unemployment is a phenomenon that is part of our lives and has a negative impact on every person. It represents a serious economic and social problem that is part of every country and cannot be solved without state intervention. The problems brought about by unemployment have an impact not only on the individual, but also on the whole society. Therefore, countries around the world are trying to fight unemployment, for example, through various tools of active labour market policy, on which the governments of individual countries spend considerable funds.

Purpose of the article: The main aim of this article is to carry out the analysis of the development of the unemployment rate in Slovakia and then compare the development of the unemployment rate in Slovakia with other V4 countries.

Methods: In this study, we made an analysis of the development of unemployment in countries such as Hungary, Poland, the Czech Republic and Slovakia, during the period 2011-2020. For the analysis, we used the data available from EUROSTAT.

Findings & Value added: The results of the study indicate that among the countries of the Visegrad Group, the Slovak Republic is the country with the highest unemployment rate. The results could be beneficial in the case of efforts to reduce the unemployment rate through various instruments or government measures, not only in Slovak Republic.

1 Introduction

Unemployment is a phenomenon that represents a problem for the whole society. It affects the lives of individuals and is part of the economies of all countries of the world. We classify unemployment among the socio-economic problems belonging to the market

---

* Corresponding author: barbora.gabrikova@stud.uniza.sk

economy. It affects not only less successful economies, but also developed market economies. The high rate of unemployment, together with the high rate of inflation, are considered the most serious economic problems ever. (Chu et al., 2021; Simionescu, Cifuentes-Faura, 2022)

Unemployment can be understood as a state in the economy when all the working population, who are of productive age and at the same time willing to work, cannot find a job on the labour market for certain reasons (Sengupta, 2009).

A situation where a high rate of unemployment of economically active people appears is an undesirable phenomenon. It is employment and productive work that represent the conditions of socio-economic development at the level of the region and the state. An increasing amount of professional literature points to the negative consequences of job insecurity in many areas of life. The impact of unemployment on the economy is mainly manifested in the economic loss that occurs when there is no full employment in the economy and therefore the output is below the potential level. (Švábová et al., 2019; Fiori et al., 2016; Eckhard, 2022)

Different measures of the labour market are used to solve the problem of unemployment, Berzinskiene and Juozaitiene (2011) talk about the regulation of relations between employees and employers, determining the amount of the minimum wage, assistance for employees and job seekers, unemployment insurance services.

Currently, even in the countries of the European Union, which are perceived as economically stable, unemployment is fought through the tools of active labour market policy (Švábová, Ďurica, Klieštik, 2019).

The classification of tools of active labour market policy by the authors d'Hombres and Santangelo (2019) is identical to the classification of tools of active labour market policy used by Eurostat and also by the Organization for Economic Cooperation and Development, these three groups are concerned:

- training courses,
- incentives for employees,
- labour market services.

Hamalainen (2002) says that the government knows how to intervene in regional labour markets through active measures. Such measures include education on the labour market and selective measures in the field of employment.

The effectiveness of active labour market policy instruments depends above all on the sufficient level of their financing and, of course, on the effectiveness of their setting. If these instruments were underfunded or ineffective, the effect of these instruments would be very low or could disappear altogether.

The main aim of this article is to analyse the development of the rate of registered unemployment in Slovakia and compare it with the development of the rate of registered unemployment in other countries of the Visegrad Group. The structure of this article is follows. In the introduction part, we focus on the basic theoretical framework related to the solved problem, it presents studies that, like us, are devoted to the given problem. A description of the individual methods of unemployment quantification can be found in the Methodology section. The analysis of unemployment development in individual countries can be found in the Results section. The results section is followed by a discussion and conclusion, which contains a brief summary of the obtained results.

2 Methods

In the conditions of the Slovak Republic, two different metrics are used to calculate the unemployment rate. The type of metric depends on the institution that quantifies unemployment, it can be the Center for Labour, Social Affairs and Family (COLSAF) or

the Statistical Office of the Slovak Republic. In the case of both metrics, the unemployment rate is quantified by the following relationship:

$$MN = \frac{NEZ}{EAO} * 100 \ [\%] \tag{1}$$

where MN represents the unemployment rate, NEZ is the total number of unemployed persons and EAO represents the economically active population. The difference between these metrics lies in the definition of unemployment and the economically active population (Illés and Ódor, 2005).

Since both of these institutions follow a different definition of the economically active population, the way they calculate the total number of the economically active population, which is a variable in the denominator of the relationship for calculating the unemployment rate, also differs. For this reason, it is possible to observe two different rates of registered unemployment in the conditions of the Slovak Republic.

Due to the fact that the legislation regarding the unemployment rate and its calculation differs in the states, this unemployment rate cannot be used for comparison between individual countries. Since in this article we are comparing the unemployment of several countries, such as the Slovak Republic, the Czech Republic, Hungary and Poland, in order to ensure a good comparability, it is necessary to use the same metric.

The European Statistical Office compiles the unemployment rate for EU member states. A "harmonized" unemployment rate based on International Labour Organization definitions is compiled. "Harmonized" mean values that concern individuals and households are used by EUROSTAT for the entire EU to ensure the comparability of member states (Illés, Ódor, 2005). In this case, the unemployment rate is calculated by the following relationship:

$$unemployment\ rate = \frac{number\ of\ unemployed}{labour\ force} * 100 \ [\%] \tag{2}$$

In this study, we will focus on the analysis of the development of unemployment in Slovakia during the period 2011-2020, while using freely available data from the Statistical Office of the Slovak Republic (www.datacube.statistics.sk).

In the case of comparing the unemployment rate of the Slovak Republic with other countries of the Visegrad Group, we work with data from EUROSTAT, because we are comparing several countries with each other, and as mentioned above, in order to be able to compare the unemployment rates of individual countries, it is necessary to use the same methodology for calculating the unemployment rate.

3 Results

We can consider the countries of the Visegrad Group as countries that operate at a similar level of economic development and are characterized by a similar employment structure (Zielinski, 2015). This is precisely why we decided to compare the development of unemployment in the countries of the Visegrad Group, which also includes the Slovak Republic.

3.1 Unemployment in Slovakia

During the monitored period of 2011-2020, it was also possible to observe the emergence of unemployment in the territory of Slovakia. The data from which he analyses the development of the registered unemployment rate in the Slovak Republic come from the official database of the Statistical Office of the Slovak Republic. The values of the

registered unemployment rate quantified in Slovakia during the monitored period can be found in the following table.

Table 1. The registered unemployment rate in Slovak republic during period 2011-2020 [%]

year	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
registered unemployment rate	13,59	14,44	13,50	12,29	10,63	8,76	5,94	5,04	4,92	7,57

Source: own elaboration according to www.datacube.statistics.sk

For a better overview of the development of the rate of registered unemployment in the Slovak Republic in the period 2011-2020, we have shown the rate of registered unemployment on a graph.
Figure 1. The development of registered unemployment rate in Slovak republic during period 2011-2020.

Source: own elaboration according to www.datacube.statistics.sk

From graph 1, it can be seen that during the observed period of 2011-2020, the rate of registered unemployment in Slovakia recorded by the Statistical Office of the Slovak Republic tended to decrease. The exception in this case was the year 2012, when the registered unemployment rate reached the highest value of 14.44%, which represented an increase compared to the previous year of 2011 by 0.85 percentage points. However, since 2012, it was possible to observe a decreasing trend in the development of unemployment. This trend could be observed until 2019, when the registered unemployment rate reached the lowest value of the entire monitored period. In 2019, the registered unemployment rate was 4.92%. However, a reversal can be observed in 2020, this year the registered unemployment rate increased to 7.57%.

The fact that in 2020 there was an increase in the rate of registered unemployment can be connected with the Covid-19 pandemic, which significantly affected the lives of people not only in Slovakia, but all over the world (Švábová and Gabríková, 2021). People started working from home, employers in an attempt to avoid bankruptcy were forced to reduce the number of jobs, or even some were forced to close their businesses (Marinescu, Skandalis, Zhao, 2021).

We can say that during the observed period, the decreasing trend of unemployment, with the exception of the last year, was perceived as desirable. The aim of labour market policymakers is to fight unemployment and increase employment (Rotar, 2018). In order for the makers of labour market policy to effectively fight unemployment in Slovakia, they

should know which of the regions of Slovakia has the highest and, conversely, which of the regions has the lowest rate of registered unemployment. After that, they can focus activities aimed at reducing unemployment in those regions where it is most needed.

The values of registered unemployment in individual regions of Slovakia can be found in the following table.

Table 2. The registered unemployment rate in the regions if the Slovak Republic during period 2011-2020 [%]

Region	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Bratislava	5.41	5.72	6.17	6.13	5.34	4.51	3.05	2.62	2.83	4.71
Trnava	8.88	9.43	9.16	8.03	6.71	4.41	2.60	2.31	2.63	5.18
Trencin	9.95	10.89	10.74	9.56	7.71	5.85	3.53	2.93	3.20	5.39
Nitra	13.27	14.08	12.52	11.21	9.71	6.96	4.05	3.12	2.93	5.50
Zilina	11.91	12.79	12.51	10.91	8.86	6.92	4.70	4.04	3.96	6.53
Banskobystrica	19.83	20.81	18.26	17.22	14.94	12.80	8.67	7.03	6.69	9.83
Presov	18.95	20.66	19.35	17.45	15.50	13.91	9.68	8.61	8.19	11.39
Kosice	18.76	19.58	17.23	15.92	14.39	12.76	9.94	8.17	7.57	10.55
Slovak Republic	13.59	14.44	13.50	12.29	10.63	8.76	5.94	5.04	4.92	7.57

Source: own elaboration according to www.datacube.statistics.sk

From the data presented in Table 2, we can see that during the entire observed period, the highest unemployment values are shown by regions such as Banskobystrický, Prešovský and Košický. The values of the registered unemployment rate in these regions during the monitored period exceeded the value of the average registered unemployment rate in the Slovak Republic.

In the following figure, we have shown the distribution of the registered unemployment rate in individual regions of Slovakia at the beginning of the monitored period, i.e. in 2011 and at the end of the monitored period, i.e. in 2020.

Figure 2. The distribution of the registered unemployment rate in individual regions of Slovakia in 2011 and in 2020.

Source: own elaboration according to www.datacube.statistics.sk

3.2 Unemployment in V4 countries

Because each of the analysed countries could use one of their own national metrics to calculate unemployment. Given that we are comparing the unemployment rate of EU

countries, we used data from the EUROSTAT database. For this reason, the individual data on the unemployment rate in Slovakia differ from the data and previous analysis.

The following table contains data on the unemployment rate in the countries of the Visegrad Group for the period 2011-2020.

Table 3. The registered unemployment rate in V4 countries during period 2011-2020 [%]

	2011	2012	2013	2014	2015	2016	2017	2018	2019	2020
Czech Republic	6.7	7.0	7.0	6.1	5.1	4.0	2.9	2.2	2.0	2.6
Hungary	11.0	11.0	10.2	7.7	6.8	5.1	4.2	3.7	3.4	4.3
Poland	9.7	10.1	10.3	9.0	7.5	6.2	4.9	3.9	3.3	3.2
Slovakia	13.6	14.0	14.2	13.2	11.5	9.7	8.1	6.5	5.8	6.7

Source: own elaboration according to https://ec.europa.eu/eurostat/web/main/data/database

For a better illustration of the comparison of the development of the rate of registered unemployment in individual countries. We will show the data from table 3 in the following figure.
Figure 3. The development of registered unemployment rate in V4 countries during period 2011-2020.

Source: own elaboration according to https://ec.europa.eu/eurostat/web/main/data/database

From Figure 3, we can see that the unemployment rate in individual V4 countries in the period 2011-2020 developed similarly, which confirms that the countries are characterized by a similar employment structure and level of economic development.

In Hungary, the unemployment rate in 2011 was only slightly lower than Slovakia, namely 11%. In 2012, the unemployment rate in Hungary was at the same level as in 2011 and started to decrease in the following year. The development of the unemployment rate in the following years in Hungary can be considered positive, as it decreased. In 2019, the unemployment rate in Hungary was 3.4%, which is lower than in Slovakia. However, in Hungary, the unemployment rate in 2020 reached higher values than in the previous year, namely 4.3%.

The unemployment rate in Poland in 2011 was 9.7%, which is also lower than in Slovakia. In the following two years, the unemployment rate rose to more than 10%. Since 2014, the unemployment rate in Poland has started to decrease. Unlike the other three countries, the V4 declined until 2020, when it had a value of 3.2%.

The Czech Republic had the lowest unemployment rate in the entire selected period of 2011-2020. In 2011, it was at the level of 6.7%, and in the following two years, the unemployment rate in the Czech Republic was 7%. Similar to the other V4 countries, the unemployment rate in the Czech Republic began to decline in 2014. The decline stopped at 2% in 2019. Similar to Slovakia and Hungary, the unemployment rate in the Czech Republic increased to 2.6% in 2020.

Compared to the other three V4 countries, the Slovak Republic had the highest unemployment rate during the entire selected period of 2011-2020. It had the worst values compared to the Czech Republic. Compared to Poland and Hungary, during the years 2011-2013, it was closer to the unemployment rate in Hungary. Since 2014, it has been closer to Poland's unemployment rate, but this changed again in 2020, as Poland achieved a lower unemployment rate than Hungary in 2020.

4 Discussion

Rezabek et al. (2022) compared the development of the unemployment rate in individual countries of the Visegrad Group, Germany, Austria, EU 28 countries, EU 15 countries and also Euro area (19 countries). Their research period was 1999-2018. They came to the conclusion that the situation was the worst in Slovakia among the countries studied, while the Czech Republic was the best.

Schwarcz, Kováčik and Valach (2021) evaluated the development of selected economic and social indicators during the period 2005-2017, focusing on countries such as the Slovak Republic, the Czech Republic, Hungary and Poland, i.e. countries belonging to the Visegrad Group. Unemployment in individual countries rose after 2008, this trend continued until 2010, the situation stabilized only in 2013. In this case, the highest number of unemployed people was measured in Poland, the lowest number of unemployed people was found in the Czech Republic. However, the authors found that during the entire period, direct investments in all the studied countries increased, except for Slovakia.

The development of unemployment after 2020 was primarily influenced by the COVID-19 pandemic. As in other countries, the COVID-19 pandemic also contributed to unemployment in Slovakia. As the country took various measures to contain the spread of the virus, in an effort to avoid bankruptcy, employers began to close their businesses and lay off workers. For this reason, unemployment began to increase in the country (Švábová, Gabríková, 2021).

5 Conclusion

In the presented article, we focused on analysing the development of the registered unemployment rate in Slovakia and comparing it with the development of the registered unemployment rate in the other countries of the Visegrad Group. We monitored the entire situation regarding unemployment during the period 2011-2020.

In the case of the Slovak Republic, we focused on monitoring the overall rate of registered unemployment and then on the rate of registered unemployment in individual regions of Slovakia. In the case of Slovakia as a whole, it can be said that unemployment tended to decrease almost throughout the observed period, with the exception of the first analysed year, 2011, and the last analysed year, 2020. In the case of the regions of Slovakia, the highest unemployment values were shown by regions such as Banska Bystrica, Presov and Kosice regions. On the contrary, the lowest values of the registered unemployment rate could be observed in the Bratislava, Trnava and Trencin regions. Based on the graphic analysis, we can conclude that the eastern part of Slovakia suffers from a high unemployment rate.

When comparing the development of unemployment in Slovakia with other countries of the Visegrad Group, we used the data available in the EUROSTAT database, because when determining the amount of registered unemployment in individual countries, it was necessary to use a uniform methodology for its calculation. Among all four countries studied, the Slovak Republic was characterized by the highest rate of registered unemployment, during the entire observed period of years, 2011-2020. On the contrary, the country with the lowest rate of registered unemployment was the Czech Republic.

The analysis of customers' communication preferences in the banking industry

Lubica Gajanova[1,*], and *Boris* Kollar[1]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: The current consequences of the financial crisis, together with the strong pressure of globalization, are causing increased banking competition and a rapid decline in the number of independent banking institutions, mainly due to numerous acquisitions and mergers. Thanks to these pressures, marketing is becoming even more effective, and the communication dogmas used in the past are slowly being removed. This change means that banking institutions can generally become more attractive to a larger part of potential clientele with their marketing communication, considering all the specifics of the segment

Purpose of the article: The aim of the paper is to reveal the possible existence of statistical dependence between the age of the respondents (clients of commercial banks) and their preference for the channel of communication with the banking institution.

Methods: The method of collecting data through a questionnaire and the contingency analysis (Pearson's chi-squared test) to process the data were chosen for this research.

Findings & Value added: Based on the results, the assumption was confirmed that all respondents, regardless of age, would prefer a similar way of being informed by their bank. Therefore, the generational difference is insignificant when it comes to communication. Customers of banking services use mobile devices as their primary engagement channel and give a lot of importance to human contact as well.

Keywords: *communication channel; preferences; banking industry*

1 Introduction

The current consequences of the financial crisis, together with the strong pressure of globalization, are causing increased banking competition and a rapid decline in the number of independent banking institutions, mainly due to numerous acquisitions and mergers. These changes in institutions have come about thanks to the pressure of clients who are not averse to innovation. Due to the rapid development of information technologies or other

---

* Corresponding author: lubica.gajanova@fpedas.uniza.sk

externalities, banking houses are pushing to shift from basic products designed for everyone to their modifications more closely adapted to the needs of individuals, which in the past were intended only for a higher segment of clients (Moufty, et al., 2022). Thanks to these pressures, marketing is becoming even more effective, and the communication dogmas used in the past are slowly being removed (Krizanova et al., 2013; Kliestikova et al., 2019a; Kliestikova et al., 2019b). This change means that banking institutions can generally become more attractive to a larger part of potential clientele with their marketing communication, taking into account all the specifics of the segment. The aim of the paper is to reveal the possible existence of statistical dependence between the age of the respondents (clients of commercial banks) and their preference for the channel of communication with the banking institution. The established hypothesis is primarily based on the assumption that all respondents, regardless of age, will prefer a similar way of being informed by their bank.

2 Literature review

Due to the homogeneity of financial products, according to Sasse (2008), it is particularly difficult for banks to position themselves in the market and differentiate themselves from the competition. As a result of this fact, he claims that the marketing success of financial services products depends mainly on the communication activity of banks, thanks to which they are able to gain a competitive advantage compared to the competition in the banking market. As stated by Su et al., (2020), the communication of banks is increasingly important not only in theoretical but also in empirical research, while the important role of communication is precisely the management of all market expectations, which are key not only for financial markets but also for the entire economy. On the contrary, Ranaldo and Rossi (2010) understand the term communication as a kind of tool through which banks achieve transparency or a high degree of responsibility. We should also not forget the fact that thanks to communication, banks have a greater influence on the expectations of financial market participants, thereby improving the effectiveness of monetary policy. Korauš (2000) also deals with the issue of communication of financial institutions. According to him, it is relevant that financial institutions inform the client about all product, including the latest ones, their features, news, lower or higher prices and, last but not least, about their comparative advantages over the competition. He also sees the importance of attracting clients, influencing their consumer behaviour, highlighting the strengths of the product, and thus raising the competitive position on the market.

In the interests of all financial institutions, high-quality communication with their current and potential clients, intermediaries and, last but not least, with the public is at the fore. According to the authors, the mission of communication consists in addressing potential clients, subsequently increasing their interest in the offered products, up to bank visits. We should also not forget that the communication between bank employees and clients should be correct, because only with their help can the problem be overcome when the consumer perceives the offer of individual banks as identical. A very similar opinion is held by Čimo et al. (2008), who consider it necessary for every bank to be able to promote itself to the public and actively communicate not only with its clients, but also with intermediaries and the public. In addition to this statement, he also states that the purpose of effective communication is to reach and interest clients with recommended products, to some extent influence their decisions, to be more prestigious compared to the competition, or to present the bank's image.

As stated by Cibáková et al. (2014), marketing communication is an integral part of modern marketing, which demands more than just creating an adequate service or product with an attractive offer and making it available to target customers of financial institutions.

Štarchoň (2017) claims that high-quality marketing communication is beneficial for banks in various areas. Thanks to it, banks reach the subconscious of the public in the widest possible range of their activities. In addition, it influences customer wishes, promotes demand and intensifies consumption. We should also not forget the fact that it expands markets and represents the bank externally. Although this fact is listed last, it does not mean that it is less important than the others are. Girchenko and Panchenko (2020) have a different understanding, who claim that the need for marketing communication in the banking sector results mainly from the fact that nowadays it is difficult for consumers to orient oneself in the crowded market of banking services. According to the authors, it is true that banks cannot do without connected, constantly evolving communication that will correspond to the changing external and internal environment. As stated by Zephaniah et al., (2020), marketing communication shapes attitude, while attitude determines customer loyalty. This is an interesting, innovative point of view, and it can therefore be assumed that through marketing communication and the effective use of all its tools, banking institutions can increase the loyalty of their customers (Somili, 2022). Chochoľáková et al., (2014) are of the unanimous opinion that banks' orientation to product development and other secondary aspects of bank management bring success in the short term, but those banks that focus on communication and building strong customer relationships are successful in long-term time horizon. According to the authors, a prerequisite for building long-term relationships is thorough knowledge of current and prospective clients, their needs, preferences and satisfaction attributes. Hagen and Schürenkrämer (2015) claim that the purpose of marketing communication in banking institutions is to provide the client with the bank's expertise. They are even convinced that the choice of products or services is not determined by the fees for banking services, but by the needs of the given client and his positive relationship with the bank. According to Bornitkov (2011), it is also important that banking institutions adapt the forms and channels of communication depending on the situation not only in the bank itself, but in the entire banking sector. Currently, in the era of the digital economy, Girchenko and Panchenko (2020) and Shpak et al. (2020) consider marketing communication to be indispensable for increasing the efficiency of banks and their profitability. Šalgovirová and Fierriero (2017) have a different view, according to which, despite the fact that the transfer of communication from conventional to digital form occurred relatively quickly, there are still segments that prefer human contact and conservative communication about banking products. Zephaniah et al. (2020) hold a very similar opinion. According to them, the personal communication between sellers and customers is the most convincing.

Marketing communication enables banking institutions to differentiate themselves from the competition and in a unique way to gain a strong position not only on the market but also in the awareness of the target segment. The aim of the paper is therefore to reveal the possible existence of statistical dependence between generations of commercial bank clients and the preferred channel of communication with the banking institution.

3 Methodology

For the purposes of this study, primary data were obtained. The own survey was conducted on a sample of 415 respondents during the fourth quarter of 2021. Based on the number of frequencies of all socio-demographic categories, it can be conclude that the representation of individual traits is in the context of the entire population and with such a large sample size, distribution of sample approximates a normal distribution, which can be proved by a central limit theorem (Kwak & Kim, 2017). The data may therefore be considered suitable for further statistical investigation.

The hypothesis is primarily based on the assumption that all respondents who took part in the marketing survey will prefer a similar way of being informed by their bank. Our goal will be to verify the dependency, or independence between the age of the respondent and their preferred channel of information. The hypothesis was established as follows:

There is no statistical dependence between the age of the respondent and the preferred channel of information.

The hypothesis processes the results from the questions that we obtained from the marketing research conducted. Specifically: What is your age? (generational stratification) and Which channel of information by the bank (communication) do you prefer the most? The importance of monitoring generational differences and their subsequent effective interpretation is growing in all sectors. Generational stratification according to Bencsik et al. (2016) that was used in this paper includes Baby boom generation (1946 - 1960); X generation (1960 - 1980); Y generation (1980 - 1995); Z generation (1995 - 2010). To find out the respondents' communication channel preferences, they were offered the following options: Phone call; SMS; Internet/mobile banking; Social sites; Video call; Face-to-face communication; Uninformed and Non-clients of the bank.

4 Results and discussion

The contingency analysis (Pearson's chi-squared test) to process the data were chosen for this research. To calculate the test statistic, we used the IBM SPSS Statistics software and is shown in Table 1.

Table 1. Pearson's chi-squared test.

	Value	df	Asymptotic Significance (2-sided)
Pearson Chi-Square	31.578[a]	21	0.065
Likelihood Ratio	33.915	21	0.037
Linear-by-Linear Association	0.743	1	0.389
N of Valid Cases	415		

Source: author according to SPSS

Significance level α was determined at 0.05. Based on the comparison of the significance level with the P-value (Asymptotic Significance), the null hypothesis was confirmed, so there is no statistical dependence between the variables examined. Based on the results, the assumption was confirmed that all respondents, regardless of age, would prefer a similar way of being informed by their bank. Therefore, the generational difference is insignificant when it comes to communication.

Several researches confirm this fact. The study according to Finn Al (2021) which was focused on exploring the use of financial products and services by Baby Boomers, Millennials and Gen Z has shown only slight differences between generations Y and Z. Other surveys (BAI, 2021; THE FINANCIAL BRAND, 2022; Lahtani, 2016) also show that although there is a noticeable percentage difference between generations, but it is not statistically significant. For this reason, the relevant results are for the whole set. The results are shown in Table 2.

Table 2. Frequency table.

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Phone call	25	6,0	6,0	6,0
	SMS/chat	57	13,7	13,7	19,8
	Internet/mobile banking	167	40,2	40,2	60,0
	Social sites	10	2,4	2,4	62,4
	Video call	44	10,6	10,6	73,0
	Face-to-face	97	23,4	23,4	96,4
	Uninformed	9	2,2	2,2	98,6
	Non-clients	6	1,4	1,4	100,0
	Total	415	100,0	100,0	

Source: author according to SPSS

The largest number, exactly 167, in percentage 40.2% of respondents marked the option "Through Mobile and Internet banking". In addition, personal contact is still preferred by clients, up to 97, respectively 23.4% of all respondents prefer this way of being informed about the latest news by the bank. The third most frequently mentioned answer, chosen by 13.7% of respondents, was the option "Through SMS messages or chat." 10.6% prefer to be informed by the bank via video call. Based on the answers, we can also conclude that 6% of respondents are satisfied with information via telephone. The smallest number of respondents (2.4%) prefers to be informed via social networks. The remaining respondents (2.2%) are not informed by the bank and 1.4% of respondents could not answer this question relevantly, as they are not clients of any bank.

5 Conclusion

In today's financial services sector, a true understanding of customer needs and requirements is more important than ever. The universality of the offer of banking services has caused that the financial market become more and more saturated with monotonous products. This is the reason for which the target markets with potential customers become narrower and the clients more distrustful. Based on this fact, it is very important for financial institutions of the banking sector to adapt marketing communication to the specifics of the target market and to identify the requirements, preferences and values of each client in the best and most efficient way possible. It is not for nothing that an institution that understands the true essence of marketing communication will achieve a competitive advantage in the form of a larger market share, customer satisfaction and loyalty.

The effect of corporate debt on the divergences of the Visegrad Group countries in debt in a global context

Dominika Gajdosikova[1,*]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: The debt analysis represents a crucial part of the management of the enterprise. This analysis plays a significant role not only in evaluating the current state but also in predicting the future development of the enterprise, which helps in its successful integration into the current market conditions. The share of equity and debt affects the overall financial stability of the enterprise.

Purpose of the article: The main aim of the paper is to carry out a debt analysis of enterprises operating in the Visegrad Group countries using adequate quantitative methods, and the subsequent description and quantification of the existence of statistically significant differences across the monitored countries.

Methods: Financial data from the ORBIS database was the basis for a detailed debt analysis. Subsequently, the non-parametric Kruskal-Wallis test, which does not assume a normal distribution of the underlying data, was used to investigate statistically significant differences between the monitored debt indicators.

Findings & Value added: Statistically significant differences concerning the country of operation of the enterprise exist between individual indicators of indebtedness. The test result shows that the most notable differences can be observed primarily between Slovakia and the Czech Republic, Slovakia and Hungary, Slovakia and Poland, and between the Czech Republic and Poland.

Keywords: *debt analysis; indebtedness indicators; non-parametric test; Visegrad group*

JEL Classification: *F34; F60; G32*

1 Introduction

In the past, the share of equity and debt has become the subject of frequent discussion in the literature because it primarily affects not only the financial stability of an enterprise but also its profitability of own capital. A high share of equity creates prerequisites for greater financial independence and stability of the enterprise (Hudakova et al., 2021, pp. 60-77).

---

[*] Corresponding author: dominika.gajdosikova@stud.uniza.sk

However, equity is generally more expensive than debt because shareholders demand a higher return than they would get by depositing their funds in a bank (Priem, 2021, pp. 9-40), which is related to the risk involved (Zwak-Cantoriu et al., 2021, pp. 432-446). However, it is possible to use financial leverage and increase the profitability of equity by using debt. High indebtedness increases the cost of debt, the enterprise becomes more unstable, and liquidity problems arise, as borrowed funds must be returned with interest (Horobet et al., 2021, pp. 122-136).

The main aim of this paper is to examine the indebtedness of enterprises operating in the countries of the Visegrad Group realized through 8 essential indicators of indebtedness using adequate quantitative methods.

The paper is divided into the following sections. The first part of the paper contains a literature review, which serves to acquaint the reader with the theoretical basis of the issue of corporate indebtedness. In the second part, methods for the implementation of debt analysis with a focus on the existence of statistically significant differences in the values of the calculated indicators due to the influence of the country of the Visegrad Group are described. The third part describes the results obtained by the previous calculation of selected debt indicators and their subsequent statistical verification, which are compared in the context of other relevant studies published worldwide. At the end of this paper, the most crucial outputs, the limitations, and future research of the corporate debt issue are summarized.

2 Literature Review

Monitoring business performance is extremely important for any enterprise that wants to be successful and is interested in achieving higher competitiveness (Matuszewska-Pierzynka, 2021, pp. 885-906). The success of the enterprise and its prosperity is a very complex activity in the current market conditions. Financial analysis provides a realistic picture of the financial condition of the enterprise by evaluating its current state and predicting its future developments. There are many financial analysis indicators, while debt indicators are intended to measure the financial risk of the enterprise. In general, increased use of debt financing will increase the return on equity if the return on assets is higher than the loan interest rate (Durana et al., 2021, pp. 425-461). Highly loaded enterprises are more sensitive to a drop in business activity. Therefore, they are more likely to be unable to fulfil their contractual and non-contractual obligations than enterprises with a lower equity ratio.

Indebtedness is closely related to the issue of the financial structure, which provides information about the share of equity and debt financing. The corporate debt can be monitored as the share of short-term and long-term capital from total capital (Jencova et al., 2021, pp. 37-46). In many cases, indebtedness is an indicator of the enterprise liquidity (for example, in the case of promissory notes). In general, in times of insufficient liquidity, obligations to suppliers are often settled by issuing promissory notes (Musa et al., 2021, pp. 375-398). Individual debt indicators of the enterprise monitor the structure of its financial resources (Valaskova et al., 2021, pp. 639-659). The share of equity and debt financing has a significant impact on the stability of the enterprise. A high share of equity makes the enterprise stable and independent. On the contrary, the enterprise with a low share of equity is more unstable, while fluctuations in the market and doubts of creditors can have serious consequences.

The use of debt primarily affects not only the risk (Virglerova et al., 2021, pp. 1011-1032) but also the enterprise profitability (Kliestik et al., 2020, pp. 371-400). In unfavourable conditions, when sales are lower for identical costs, the enterprise may have higher financing costs than revenues. The enterprise can thus get into difficulties with repaying its obligations. However, corporate debt is not always only a negative

characteristic of the enterprise. It is true that the higher the indebtedness, the greater the business risk and the related difficulties in obtaining sources of debt financing. In general, the right combination of equity and debt financing, which refers to the selection of an appropriate capital structure, is one of the most crucial questions in the enterprise financial management (Kovacova et al., 2022, pp. 41-59).

3 Methods

The main aim of this paper is to examine the indebtedness of enterprises operating in the countries of the Visegrad Group realized through 8 essential indicators of indebtedness using adequate quantitative methods.

Financial parameters from the ORBIS database, considered a provider of business and financial data on more than 400 million private and public enterprises operating worldwide, were essential for a comprehensive debt analysis. The database provides financial data on 100,057 enterprises operating in the Visegrad Group countries for the monitored period of 2015-2020, which was the basis for a debt analysis. The data from the database had to be adjusted appropriately because not all enterprises were suitable for the debt indicators calculation. Enterprises that do not provide all the input data necessary for the debt analysis in the monitored period were removed. Outlying values were removed from the dataset to reduce the informativeness of the obtained results of the calculated debt analysis. After the final adjustment, the database contains 10,762 enterprises whose elementary identification data are summarized in Table 1.

Table 1. The elementary data of the enterprises operating in the V4 countries in the period under the review

Indicator		Absolute Frequency	Relatively Frequency
Country	SK	2,441	22.68
	CZ	2,503	23.26

Source: own elaboration

A comprehensive analysis focused on the indebtedness of enterprises operating in the Visegrad Group countries in the monitored period was carried out using eight debt indicators. Formulas necessary for the subsequent calculation are summarized in Table 3.

Table 3. Summarized formulas of indebtedness indicators

Ratio	Algorithm
Total indebtedness ratio	Current and non-current liabilities to total assets
Self-financing ratio	Shareholders funds to total assets
Current indebtedness ratio	Current liabilities to total assets
Non-current indebtedness ratio	Non-current liabilities to total assets
Debt-to-equity ratio	Current and non-current liabilities to shareholders funds
Interest coverage ratio	Earnings before interest and taxes to interests paid
Equity leverage ratio	Total assets to shareholders funds
Insolvency ratio	Current and non-current liabilities to receivables

Source: Valaskova et al. (2021)

The financial analysis regarding the indebtedness of enterprises was carried out in the following methodological steps.
1. Firstly, it was necessary to calculate the individual monitored debt indicators separately for enterprises operating in the Visegrad Group countries in the monitored time horizon, set from 2015 to 2020.
2. In the next step, the normality tests (Kolmogorov-Smirnov and Shapiro-Wilk tests) were used to determine if a dataset is well-modelled by a normal distribution. The normality tests are supplementary to the graphical assessment of normality and its ability to detect whether a sample comes from a non-normal distribution. The p-value is interpreted against a significance level of 5 % and finds that the test dataset deviates significantly from normal distribution.
3. The Kruskal-Wallis test, a non-parametric alternative to one-way ANOVA test, was used to determine that at least one sample stochastically dominates one other sample. The test extends the two-sample Wilcoxon test in the situation where there are more than two groups. The Kruskal-Wallis test result does point to a significant difference between groups but does not identify which pairs of groups are different, so the Bonferroni correction was used to limit the possibility of getting a statistically significant result and for counteracting the multiple comparisons problem.

4 Results and Discussion

The assessment of corporate indebtedness is generally based on various debt indicators, which primarily examine the structure of the financing sources of the enterprise. These ratios express and quantify the extent to which the enterprise primarily uses debt to finance

its needs. The following indebtedness indicators were selected to fulfil the main aim of this paper, namely the total indebtedness ratio, self-financing ratio, current indebtedness ratio, non-current indebtedness ratio, debt-to-equity ratio, interest coverage ratio, equity leverage ratio, and insolvency ratio. The average values that individual debt indicators reached in the monitored period are summarized in Table 4.

Table 4. 6-year average values of indebtedness indicators

Ratio	6-year average values
Total indebtedness ratio	0.538
Self-financing ratio	0.462
Current indebtedness ratio	0.388
Non-current indebtedness ratio	0.149
Debt-to-equity ratio	1.531
Interest coverage ratio	13.454
Equity leverage ratio	2.531
Insolvency ratio	2.244

Source: own elaboration

The fundamental indebtedness indicators, indicating the extent to which the enterprise needs are covered by its equity and debt financing sources, are the total indebtedness ratio and the self-financing ratio. In general, these indicators are complementary, i.e. their sum must be equal to 1, or 100 %. The total indebtedness ratio, expressing the ratio of current and non-current liabilities to total assets of the enterprise, reached an average value of 0.538 in the monitored period, which means that 1 € of total assets is covered by 0.538 € of the total liabilities of the enterprise operating in the Visegrad Group countries. In general, many investors prefer an enterprise with a total indebtedness ratio between 0.3 and 0.6. However, a total indebtedness ratio lower than 0.4 is considered better because this indicator is crucial in assessing the financial risk of the enterprise. On the contrary, if the total debt ratio is higher than 0.6, the enterprise face problems in obtaining financial sources (Stefko et al., 2021). A complementary indicator to this indicator is the self-financing ratio, which expresses the ratio of shareholders' funds to the total assets of the enterprise. The calculated debt indicator result shows that 1 € of total assets is covered by 0.462 € of shareholders' funds of the enterprise. If the enterprise primarily uses debt to finance its business activity, it is crucial to monitor the debt financing sources structure using the analysis of partial indicators of the enterprise financial structure, including the current indebtedness ratio and non-current indebtedness ratio. These indicators express the use of short-term and long-term debt in the enterprise. The more the share of bank loans and aid in the financing of the enterprise grows, the more the enterprise depends on this form of financing and the importance of knowing the structure and conditions of this financing for its financial management grows (Michalkova et al., 2021, pp. 276-295). From the calculated results, it is clear that enterprises operating in the V4 countries use an average of 38.8 % of short-term and 14.9 % of long-term debt to finance their business activity. The debt-to-equity ratio indicates the ratio of the current and non-current liabilities to shareholders funds of the equity. The enterprise uses this ratio to evaluate how much leverage it uses. From the financial analysis results focused on indebtedness, it is clear that 1.531 € of the corporate debt corresponds to 1 € of shareholders funds. The next debt indicator is the interest coverage ratio, which indicates the enterprise financial performance. This indicator is one of the most crucial indicators of indebtedness, which expresses how many times the profit exceeds the value of the interest that the enterprise must repay and how many times the enterprise is able to cover the interest from debt after paying all the costs associated with the business activity. Hafeez and Kar (2021, pp. 674-688) state that

the optimal value of the indicator is considered to be 3. This indicator reached an average value of 13.454 in the monitored period. The enterprise indebtedness is one of the cardinal components of the financial balance, in which the equity leverage ratio participates in the elementary questions of financial management of the enterprise. The debt indicator is the inverse of the self-financing ratio. Financial leverage is usually based on the idea that debt financing is conventionally cheaper than equity financing. If the value of the equity leverage ratio decreases, the enterprise has an excess amount of capital from its equity. Otherwise, the share of equity in total assets is insufficient. Indeed, the greater the share of debt, the greater the indicator of equity leverage, i.e. high financial leverage represents high indebtedness of the enterprise (Gungoraydinoglu and Oztekin, 2022). The analysis results show that 1 € of shareholders' funds accounts for 2.531 € total assets of the enterprise. The last calculated indicator within the realized debt analysis was the insolvency ratio, which compares the current and non-current liabilities to receivables of the enterprise. In the monitored time horizon of 6 years, the average value of the indicator was 2.244, which means that 1 € of receivables is covered by 2.244 € of total liabilities of the enterprise.

The detailed debt analysis of enterprises operating in the countries of the Visegrad Group was primarily focused on assessing the existence of statistically significant differences between the individual monitored indebtedness ratios concerning the country in which the business entity operates. The aim of the analysis was to point out whether the average values of the debt indicators are the same in all the countries of the Visegrad Group or whether there are statistically significant differences between the individual values of the ratios.

Firstly, it was necessary to verify the normality of the dataset by using the Kolmogorov-Smirnov and Shapiro-Wilk tests, the results of which, however, rejected the null hypothesis that the data come from a normal distribution. The non-parametric Kruskal-Wallis test was used to examine the existence of statistically significant differences between the monitored indicators of indebtedness with respect to the country because the Kruskal-Wallis test does not assume a normal distribution of the data compared to the analogous one-way ANOVA and is not sensitive to outliers in the dataset. The Kruskal-Wallis test result is summarized in Table 5. Statistically significant differences concerning the country of enterprise operation exist between individual indebtedness indicators because the p-value of the test is lower than the chosen significance level for all ratios, so the null hypothesis is rejected.

Table 5. The output of the Kruskal-Wallis test

	TI	SF	CI	NCI
Kruskal-Wallis H	379.269	378.396	458.908	76.086

Source: own elaboration

Due to the existence of statistically significant differences between the eight monitored indicators of indebtedness, a post hoc analysis was carried out in the next step, which pointed to significant pairs between which countries have the most crucial differences in the values

of the indicators. The result of the pairwise comparison of the monitored enterprises considering the country of its operation is summarized in Table 6.

Table 6. The output of the pairwise comparison of countries in which the enterprises operate

Source: own elaboration

The test results show statistically significant differences in the total indebtedness ratio, debt-to-equity ratio, equity leverage ratio, and insolvency ratio, especially between the Czech Republic and Poland, the Czech Republic and Slovakia, Hungary and Slovakia, and Poland and Slovakia. There are also differences between the Czech Republic and Hungary in the current indebtedness ratio. On the contrary, there are statistically significant differences between all pairs of countries of the Visegrad Group, except Hungary and Slovakia, in the non-current indebtedness ratio. There are no statistically significant differences in the monitored indicator, and the median values are the same. The statistically significant differences were not confirmed in the interest coverage ratio only between Slovakia and the Czech Republic. The Visegrad Group was formed from the post-socialist countries of Central Europe (the Slovak Republic, the Czech Republic, Poland, and Hungary) and thus created an informal grouping of neighbouring EU member states, linked not only by a common geographical location but also by history (Sedliacikova et al., 2021, pp. 99-116). These four countries were very similar in the past in culture, location, customs, religion, economic development, and intellectual values (Durana et al., 2021, pp. 39-55). In the past, many authors have studied the indebtedness of enterprises in the countries of the Visegrad Group. According to Grzegorzewska and Stasiak-Betlejewska (2014, pp. 315-322), the largest share of self-financing is visible in Polish enterprises. The difference between Poland and other countries is quite significant, which proves the high financial independence and security of Polish enterprises. However, the average share of self-financing in Czech enterprises is increasing interannual, and the equity financing is decreasing in Hungarian enterprises, which increases the debt during the monitored period 2007-2012. At the same time, the authors state that the smallest extent of financing the assets of the enterprise with equity is in Slovak enterprises. According to Cernohorska et al. (2017, pp. 175-187), the Czech and Slovak enterprises primarily use long-term bank loans compared to the other countries of the Visegrad Group. A smaller share of long-term loans thus concerns Polish and Hungarian enterprises. On the contrary, according to Ruckova and Skulanova (2022, pp. 117-136), short-term loans are most widely used by Czech and Slovak enterprises. According to the authors, short-term loans are less important for Hungarian enterprises, while Polish enterprises use short-term loans to the smallest extent. In their publication, the authors pointed to the fact that there is a visible difference between the involvement of these capitals in Polish enterprises compared to the other monitored countries. Kluzek and Schmidt-Jessa (2022, pp. 451-481) focused on examining the level of indebtedness and the impact of taxation on the capital structure of enterprises that operate within national and multinational groups in the countries of the Visegrad Group, while the authors pointed out in the results generally to a higher level of indebtedness of domestic corporations. However, many other authors have also studied the debt level in the conditions of the Visegrad Group countries.

5 Conclusion

One of the tasks of financial management is deciding on the need for capital and choosing the appropriate form of financing the development activities of the enterprise. Many studies have been conducted dealing with the preference of a specific source of financing for business activities, but these studies were and are often contradictory. Therefore, it cannot be claimed that there is a universal procedure for choosing a financing source for the development of an enterprise. The enterprise is affected not only by many microeconomic but also macroeconomic factors that, on the contrary, cannot be influenced by the business unit. Indebtedness indicators point to the structure of the financial sources of the enterprise, namely the share of equity or debt financing in the total assets. These indicators indicate the degree of financial stability of the enterprise, where a high share of its own resources makes the enterprise more independent and stable. On the other hand, higher indebtedness increases the risk of financial instability of the enterprise, but in a balanced market environment, the use of equity is more expensive for the enterprise than the use of debt. The indebtedness indicator is most likely to change when financing business activities by debt. In general, an increase in the corporate debt can have a negative as well as a positive impact on the enterprise performance. Growing indebtedness reduces the tax base by the amount of the increase in interest cost, which has a positive effect on the financial result of the accounting period, but it brings with it certain risks.

The main aim of this paper was to carry out a debt analysis of enterprises operating in the Visegrad Group countries using adequate quantitative methods, and the subsequent description and quantification of the statistically significant differences across the monitored countries. A detailed corporate debt analysis was primarily focused on assessing statistically significant differences between the individual monitored indicators of indebtedness with respect to the Visegrad Group country in which the business entity operates. It is clear from the test results that statistically significant differences exist primarily between the Czech Republic and Poland, the Czech Republic and Slovakia, Hungary and Slovakia, and Poland and Slovakia.

Despite the contribution of this paper to the extant literature, the following limitation needs to be highlighted. The scope of the paper (i.e. the focus only on one formation of Visegrad group) limits the extent of generalization of the findings. Future research should examine this phenomenon in more formations, or in a longer time horizon than set for this research, to determine whether there will be differences in the findings and allow for greater generalization and applicability.

Impact of Blockchain application in selected global corporations: Evidence from event study approach

Vladimíra Gimerská[1,*], and *Michal* Gimerský[1]

[1]Technical University of Košice, Faculty of Economics, Němcovej 32, 040 01 Košice, Slovakia

Abstract

Research background: Blockchain technology was first described in 2008 and is widely associated with cryptocurrencies, but it also founds its purpose in a business environment. Most of the real-life applications of this technology in corporations started in 2019, and it has been tested globally in international companies. As the evidence shows, this emerging technology is mainly used in logistics, supply chain and finance. Moreover, blockchain is expected to help drive global GDP by trillions of USD in the next ten years, which underlines its importance.

Purpose of the article: This article focuses on publicly traded companies that are active globally and have recently applied blockchain technology to their processes. The aim is firstly to identify which companies already used blockchain, select only publicly traded companies and analyse if and to what extent the adoption of blockchain influences the stock price.

Methods: Using fundamental research and event study methodology, we study stock price movement before and after the official announcement of blockchain implementation into the processes of global corporations. By calculating cumulative abnormal returns of stocks in 2 periods, before and after implementation, we observe the behaviour of returns in the stock exchange. Abnormal returns are identified.

Findings & Value added: After individual analyses of selected corporations, it is possible to claim, in general, that implementation could positively impact stock price development, but not immediately after implementing blockchain.

Keywords: *blockchain; supply chain; digitalisation; event studies*

1 Introduction

Blockchain technology, as described initially in 2008 by Nakamoto is mostly used in cryptocurrencies; however, it can also be used in the corporate environment as it can efficiently accommodate various information settlement in encrypted way that ensures trust

---

(Mendling, 2018). As businesses keep their eyes open for real applications, the importance of this technology is gaining momentum. Most crucial part of implementing new technology in 21. Century is cybersecurity. Such potential threads are well described by Leng et al. (2021), especially cybersecurity issues in smart manufacturing process. On the other hand, positive relationship between blockchain technology, company's performance, supply chain resilience and business model design was identified. (Li, 2022)

Moreover, it can shape and transform business, according to PWC (2020), having the potential to increase the global GDP by 1,76 trillion USD by 2030. This would be achieved in areas such as Provenance (verification and transformation of the supply chain), Finance (clearing of payments/financial instruments), Identity check and confirmation, Contracts and Claims resolution and the least being Customer engagement - integration with CRM platforms such as Salesforce or Dynamics365 (PWC, 2020).

Our study aims to identify the influence blockchain has on selected publicly traded companies that announced a blockchain technology project. Most of the projects started between 2018-2020, and we constructed a sample of 10 companies from different segments or industries: Automotive, Finance, Food & beverages and Technology. After that, we apply the event study approach to analyse whether the first announcement or information about starting a blockchain project significantly influences the stock price around the event day.

The paper is organised into the following sections: In the Literature review, we summarise recent studies on this or similar topics to see at which level the current knowledge in this field. The next part describes the Methodology and Data used in our research and the calculation procedure. The final parts are Results and Conclusion, where the most important findings are described and discussed.

2 Literature review

Blockchain as a technology has been evolving since its first publication, and most real corporate applications were announced in 2018 and later. Furthermore, literature evidence from recent years shows that most interest in blockchain technology is connected to cryptocurrency, although evidence shows that this technology is feasible for use in different industries, such as supply chain, finance, health, energy, automotive, agriculture and food (Erol et al., 2021). However, this paper aims to analyse blockchain as a viable technology used in various global corporations and study the market reactions to the company's announcement of the first real adoption of this technology.

When analysing literature regarding market reactions to such announcements, there are already a few studies worth mentioning, such as Cheng et al. (2019) or Cahir et al. (2020), where a rather positive effect on willingness to invest into stocks of such companies was observed. A recent study by Chen et al. (2022) are relatively close to our aims and approach, however, in their study, only China and Chinese companies are selected, and the analysis goes beyond pure blockchain announcements. Two groups of companies are constructed – high tech firms and non-high tech firms, both with plans to adopt blockchain in the future. Altogether 302 companies listed on the Shanghai and Shenzhen Stocks Exchanges in 2016 - 2020 were selected. For analysis, two periods are constructed with 41 and 11 trading days. Results showed that blockchain announcements by high-tech companies attracted more investors' attention with stronger stock price reactions, as investors find such companies more credible (Chen et al. 2022).

Another event study analyses financial corporations that use blockchain and the reactions of their stocks during the COVID-19 pandemic. Here again, the common parameter is that high-tech companies, either members of blockchain consortiums or those with some

technological advantages, have better positive stock development results, preventing potential losses during pandemic-related announcements (Paul et al., 2022).

In the study by Liu et al. (2022) announcements concerning blockchain are considered and market reaction is observed. However, in this particular case only 1 company is observed but a total of 143 blockchain announcements are analysed. A combination of event study approach with multivariate regression is used to study the reaction of the market and also to identify factors influencing the change. Positive market reaction on the release day is observed. The announcements are categorised to find that those marked as strategic-level cause more positive market reaction.

3 Methods

3.1 Methodology and data

In this paper, we use the event study approach to quantify the effect of announcements regarding blockchain applications on stock prices. For this purpose, we selected ten globally active corporations and retrieved from the platform Investing.com daily stock close prices for the last ten years. Additionally, to compare prices with broad market performance, we selected MSCI World Index. Since selected companies and indices representing benchmarks are traded in different countries, the problem with non-trading days occurred, which is a common problem in event studies. As in the sample, individual stocks and indexes are present, and a discrepancy in the form of different trading days count can occur. We do not address this problem by setting missing values as zero daily stock returns, as suggested by Kallunki (1997) and Leemakdej (2009). Instead, we have chosen trade to trade method mentioned by Campbell et al. (2010), which involves omitting non-trading days completely. This approach was used in our paper.

After the data preparation phase, we searched for specific announcements regarding real blockchain implementation projects in this paper considered event days (T0). Most of the projects started between 2017-2020. We continue by setting the event window (30 days prior to and after event day) and estimation window, which starts 120 days before the event window (Figure 1).
Figure 1. Event Timeline – Estimation Period and Event Period

Source: Own illustration

As a next step, we calculate the actual and expected returns of each company and benchmark index using the OLS Market model, which is described by formulas below:

$$R_{i,t} = \ln\left(\frac{P_{it}}{P_{it-1}}\right)$$
(1)

$$E(R_{i,t}) = \alpha_i + \beta_i \cdot R_{mt}$$
(2)

$E(R_{i,t})$ represents the expected return of Company *i* on day *t*, and R_{mt} demonstrates the return of the benchmark index (in our case MSCI World) at time *t*.

Afterwards, we calculate the individual company's abnormal returns AR_{it} during the event window and cumulative abnormal returns CAR_{it}. Whereas AR is a difference between actual and expected returns, *CAR* is a sum of previous *AR*s. The mentioned procedure is expressed by following two formulas:

$$AR_{i,t} = R_{i,t} - E(R_{i,t}) \tag{3}$$

$$CAR_{i,t} = \sum_{t=T1}^{T2} AR_{i,t} \tag{4}$$

In the next step, we compute average ARs for each day, and as a result, CAR of all average abnormal returns obtained.

In the Table 1 we summarise our sample and corresponding announcement days and sources. Selected corporations come from the Automotive, Finance, Food & Beverages and Entertainment sectors.

4 Results

After calculations according to our methodology described above we constructed chart with cumulative abnormal returns of 10 observed companies. After that we performed statistical tests using SPSS Software. Our results, as seen in Figure 2 and both tables afterwards, show that returns on the event day T0 are slightly positive, and for 4 out of 10 days after the announcement we can also observe positive performance. However, ten days before the announcement, there were six days with negative returns, which could be caused by other information or rumours about these projects. The market received this as slightly negative, which can be interpreted as a potential risk of new technology implementation.
Figure 2. Cumulative Abnormal returns in the event period

Source: Own calculation in MS Excel

Table 2 includes one-sample statistical results which represent the whole event period. In the time period prior to event day we see 14 days of positive average performances out of 30 days. According to our data, period after event day performed similarly, in this case 50% of days were positive.

After performing statistical tests, following days as seen in Table 3 were tested as significant - at a 10% level of significance: days: t-23, t-5, t+27 and the day t-30 tested as significant on a 5% significance level.

Source: SPSS Statistics

Finally, different periods were tested for their statistical significance, as shown in Table 4 and Table 5. The length of periods was set at 30, 15, 5 days, and 1 day prior and after t0, and cumulative ARs of each company were computed. According to our results, the average performance in three out of four periods was at a positive level, and only one period (-5, 5) was slightly negative in total. However, only three companies were negative, which could be seen as rather positive.

Even if the shortest period (-1, 1) was positive on average, six individual companies performed negatively.

No company had significant AR after the announcement except Tata Motors, where a negative AR of -8,59% was observed on the third day after T0.

The most volatile results after t0 occurred in the case of Tata Motors, BMW, AT&T and Anheuser-Busch. In general, in most cases, a positive upward trend was present. However, the results before t0 show that in the case of companies Anheuser-Busch, Tata Motors, Volkswagen and Walt Disney, there were slightly negative abnormal returns in the period t-22 until t-16 and slightly positive in the period t-15 to t-11.

However, as the data show in Table 5, even if selected companies have positive performance on average, this performance is not statistically significant according to our data.

Table 4. One-Sample Statistics of various intervals

	N	Mean	Std. Deviation	Std. Error Mean

Source: SPSS Statistics

As our data suggests, there was no statistical significance in all four tested intervals.

We want to mention that within this research, we considered only blockchain announcements as the only event influencing the stock price. All other factors that could affect stock price were not acknowledged.

5 Conclusion

Blockchain as an emerging technology is getting more and more popular not only in the business area but also within academia. As this technology is seen as disruptive technology within the company, our aim of this paper was to analyse what influence has this blockchain technology on the company. In this paper, we focused on selected international companies

and published announcements concerning implementing blockchain technology. Using the event study approach, we observed the market reaction in the period that preceded the event, the announcement day, and the period after the event. In general, a positive upward trend was observed after the announcement, especially in the case of Tata Motors, BMW, AT&T and Anheuser-Busch. Around three weeks before the event day, negative abnormal returns were present on the tested sample. However, being closer to the event day, a positive trend has been present for two weeks. The strongest results show Tata Motors, VW, Walt Disney and Anheuser-Busch.

We encourage further research to expand the selected sample, add companies from different sectors, and compare results with a control group of similar companies listed on the stock market that did not consider or implement blockchain technology.

Rumour or official interest rate change announcement – Influence on green investment performance

Michal Gimerský[1,*], and *Vladimíra* Gimerská[1]

[1]Technical University of Košice, Faculty of Economics, Němcovej 32, 040 01 Košice, Slovakia

Abstract

Research background: When planning an asset allocation, the two most important factors are taken into consideration for institutional and individual investors - performance and transaction costs. Recently, popular investments globally are ETF funds labelled as "green", "impact", or ESG, focusing on positive influence on the environment while aiming for value appreciation of an investment. As volumes of such funds are rising, there is a need to study these investments from different perspectives.
Purpose of the article: This paper analyses selected green ETF funds by two criteria: AUM and performance. Changes in interest rates can influence the performance of a fund. There are also rumours before the official announcement, so these need to be considered when making an investment decision. Finally, we aim to find out if official or non-official information has a bigger impact on the performance of a green fund.
Methods: Firstly, a sample of 10 green funds is identified, and daily close prices are obtained. Secondly, using the event study method, performance is analysed around two events – the official FED rate hike on March 17th, 2022 and unofficial information prior to it.
Findings & Value added: The analysis of selected funds indicates a significant influence of FED rate hikes on performance after the official announcement. Interestingly, unofficial information in the form of rumours also has a significant impact as in the global connected markets; information spreads quickly before an official statement, which could affect the investment decision.

Keywords: *green funds; ETF; impact investing; rate hikes; portfolio management*

JEL Classification : *G11; G14; F21*

1 Introduction

Green investing is an especially popular term as such investments are offered to the public by investment advisors and various banks. According to Google Trends statistics from the USA, at the beginning of 2020, interest in this topic started to rise from level 7 and oscillated

---

* Corresponding author: michal.gimersky@gmail.com

around 50 in mid-2022. This indicator expresses popularity where the highest level of 100 points shows maximum popularity. Investment funds, which in their prospectus do not mention social responsibility or sustainable investing, are nowadays hard to find.

Bloomberg predicts that ESG-related investments can be 53 trillion USD by 2025, which would be 30% of global assets under management. Of the total amount, ETF funds represent 190 billion USD by the end of 2021. European ESG market was the biggest in 2021 (Le Sourd and Safaee, 2021) but the pace at which the US market is rising aims for the first place as there was a 318% in assets inflows in 2020 (Bloomberg.com, 2021). This is the main reason and motivation of this paper to concentrate research mostly on the US market.

2 Literature review

Thirty years ago, environmental damage of great scale shocked the world and gained public attention to green investing. This ecological catastrophe was caused by Exxon Valdez in the 1990s when a great amount of oil was spilled in Alaska. Between 615 oil spill events happened between 1989 and 2018, with more than seven metric tons of oil (Leahy, 2019).

One of the definitions of investments that positively impact the environment could be described by a shortcut ESG - Environment, Social and Governance. More specific areas fall under those three categories. Under the category environment are themes like Climate, Resource scarcity, Waste and Water and Biodiversity. The second category is Social, with Human Capital, Safety and health, Demographic change and Food security themes. The last ESG category stands for Governance, which could be defined by Risk and Reputation management, Oversight structures, Corporate Behavior/Governance and Compliance and Corruption. (Gabler Wirtschaftslexikon, 2018)

Regarding ESG ratings, there is quite a disagreement among rating agencies. The analysis shows that more ESG disclosures lead to more disagreement between agencies, leading to higher return volatility. Most prominent ratings are constructed by Morgan Stanley Capital International (MSCI ESG rating system), Thomson Reuters ESG Scores and Sustainalytics ESG Rating Research Methodology (Christensen et al., 2022).

When searching for literature on ESG investing, we first made a clear differentiation between investments in bonds and equities so that the focus lies on equities. Evidence shows that green stocks outperform brown stocks when climate issues intensify (Pastor et al., 2022).

A vast amount of literature exists that focuses on the influence of Covid-19 on the stock market. An event study by Gregory (2022) which involved companies from S&P1500, showed that especially non-financial US companies with implemented ESG strategy had better market development and higher risk-adjusted returns during the first year of the global pandemic. Another event study considered 62 suitable ETFs and took the market crash in February 2020 as an event day. The researchers looked into the period before and after the crash, concluding that lower-rated ETFs outperformed the higher-rated ETFs. Interestingly, ESG ETFs did not exceed the losses of other investments during the crash, suggesting that this type of investment could be considered suitable during downturns. (Pavlova and de Boylie, 2022). Causalities and spillovers between NASDAQ indexes (clean energy, Composite Index and Global Select Market Composite) and energy indexes before and after Covid-19 were also tested to find that both sustainable and green indexes impact each other in the long term and from the start of the pandemic connectivity rose significantly. Evidence shows that sustainable investments performed better during the pandemic than other standard strategies (Sharma et al., 2021). In line with this result is Omura et al. (2021), who investigated equity market performance in most important regions and globally to find that during pandemics, ESG funds did not outperform benchmarks marked as SRI (Social Responsible Investing). However, there is a great amount of attractiveness of such

investments. In the Australian market, a study of 244 ETF funds with ratings from Morningstar uncovered that portfolios with lower carbon and fossil fuel exposure tend to outperform in the Covid-19 period. ESG portfolios are more likely to experience more volatility in stock returns, but their characteristics add an additional layer of protection against market drops (Sun and Small, 2021).

Evidence from Japanese ESG-rated companies showed no evidence that companies with higher ESG scores also have higher abnormal returns, but those with ESG rating outperformed companies without this rating (Takahashi and Yamada, 2021).

The ESG performance analysis of so-called "sin stocks" is very interesting, representing the Alcohol, Tobacco and Firearms industry, where 79 of such companies are compared to the control group of structurally similar companies from traditional sectors. As a result, sin stocks lack ESG practices and are exposed to more severe issues (Paradis and Schiehll, 2021).

3 Methods

3.1 Data and Methodology

In this paper, we are observing two events (two announcements). The first event is the rumour about a possible change of interest rate on April 12th, 2021 (Politi et al., 2021); however, as it was a non-trading day in the US and Friday followed by a weekend, we set Monday, April 5th as the event day. The second event occurred almost one year later, on March 17th, 2022, when FED officially announced a rate hike (Federalreserve.gov, 2022).

We decided to set the event period at the length of 43 days, beginning with t-21 and ending with t+21. The estimation period has 100 days and starts in t-121 and ends in t-22. The visualisation of observed periods – estimation and event window are presented in the Figure 1.
Figure 3. Event Timeline – Estimation window and event window

Source: Own illustration

After setting observed periods, we selected a sample of 10 ETF Funds from the platform www.ETF.com, where we used AUM and ESG description of a fund as a selection criterion. We filtered only Equity funds. Six funds in the sample are from segment US Total Market, one ETF fund Developed Markets Ex-North America Total Market, two funds from segment Emerging Markets Total and one fund labelled as Global Ex-US Total Market. Selected funds are summarised in Table 6.

Table 6. ESG funds

Ticker	Name	Segment	Issuer	Expense Ratio	AUM

Source: Own illustration

As a next step, we obtained daily close prices of each fund from www.investing.com. We then calculated the actual returns of each ETF ESG fund as a continuous logarithm (Formula 1).

$$R_{i,t} = \ln\left(\frac{P_{it}}{P_{it-1}}\right) \tag{5}$$

To obtain expected returns, we used OLS Market Model in which, as a benchmark index, we chose S&P500 (Formula 2).

$$E(R_{i,t}) = \alpha_i + \beta_i \cdot R_{mt} \tag{6}$$

$E(R_{i,t})$ represents the expected return of ESG fund i on day t, and R_{mt} demonstrates the return of the benchmark index, which in our case is index S&P500.

Afterwards, we calculate the individual ETFs abnormal returns AR_{it} during both event windows and also cumulative abnormal returns CAR_{it}. The AR represents the difference between actual and expected returns, CAR is a sum of previous ARs. The mentioned procedure is expressed by following two formulas:

$$AR_{i,t} = R_{i,t} - E(R_{i,t}) \tag{7}$$

$$CAR_{i,t} = \sum_{t=T1}^{T2} AR_{i,t} \tag{8}$$

In the next step, we compute average ARs for each day, and as a result, CAR of all average abnormal returns is calculated.

4 Results

In this section divided into two parts, we summarise the most important results of our calculations and observations.

4.1 The announcement (rumour) in April 2021

As presented in Figure 4, on day t-16, we see the start of a gradual decline of *CARs* which continues for the whole observed period, except for four days around t0 (t-3 to t+1), where only a small change of performance is observed. For this period, approximately 4,00% decline was measured in our sample. Additionally, volatility was quite high from day t-19 to t-13, with difference from -0,60% to 0,60%.
Figure 4. Cumulative average Abnormal returns of ESG funds - event window in 2021

Source: Own calculation in MS Excel

Table 7. One-Sample T-TestTable *7* represents one sample T-test for all days in the event period, and the results show that from all 43 observed days, 19 were tested as significant: 3 days at a 1 % level of significance, 7 days at 5% level of significance and 8 days at 10% significance level.

4.2 The official announcement in March 2022

The same procedure was repeated for the second event - the official announcement on March 17th, 2022. The cumulative abnormal returns are presented in Figure 5. After a steep decline lasting six days from t-16 until t-8, we observed an upward trend until t+12.
Figure 5. Cumulative Abnormal returns of ESG funds - event window in 2022

Source: SPSS Statistics

The last table below summarises eight intervals where only three are statistically significant, all on the significance level of 5%. This finding is interesting as for official announcement; fewer intervals are significant than in the case of rumour (with five statistically significant periods). What is more, six out of eight periods reached negative average performance.

5 Conclusion

Within this paper, we performed an event study analysis focusing on the first FED interest rate hike in March 2022, done after two years of pause in increasing interest rate changes. We tried to understand if rumours concerning rate hike prior to the official announcement

would cause different performances on selected samples. We focused our analysis on ten ETF equity funds from the ESG category, which were chosen by AUMs.

The results of this paper show that for both announcements and event periods, similar cumulative abnormal returns were present at about -4% in total. However, in the case of rumour, we observed a steady decline for almost the whole period. The official announcement caused more volatile movements with the first sharper decline followed by a week upward trend but still in negative territory. More favourable tests for statistical significance were in the case of rumour event, where more observed periods showed statistically significant. The results are in line with theory in general, as decrease in interest rate causes a decline in the stock market, because risk-free investment would be favoured by investors.

It would be interesting to cluster ETF ESG funds by segment and expense ratio or total costs and perform a similar analysis. Additionally, different benchmark indexes could also be taken into consideration in the future research.

A satisfied employee as a key factor in the success of a company

Martina Gogolova[1,*], and *Olga* Ponisciakova[1]

[1]University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: Employee satisfaction is a key factor in a company's success. A satisfied employee creates more value and profits for the company. Nowadays, the employees of every company perceive job satisfaction as a whole, in which they are provided with other benefits in addition to the salary. Suitable working conditions for the performance of work are also important at work, where there is a good working climate at the workplace and, above all, where they get satisfaction from their work and feel satisfied. Motivation to work can come from within, when employees themselves are sufficiently motivated and enjoy their work, or they may need motivation from the outside in the form of additional benefits.
Purpose of the article : The paper deals with the proposal for evaluating selected factors of employee satisfaction that are based on personnel marketing. By evaluating the given factors in the matrix of importance and satisfaction, companies will be able to find out and solve the factors that are currently very important to the employees of a given company, but at the same time they are very dissatisfied with them. The proposed employee satisfaction methodology can be used by companies that are interested in having satisfied and loyal employees.
Methods: Induction, deduction, analysis, synthesis, questionnaire survey, statistical methods
Findings &Value added: Proposal of a methodology for evaluating employee satisfaction in companies in Slovakia.

Keywords: *employees, satisfaction, importance*, *evaluation criteria, personal marketing*

1 Introduction

A satisfied employee is an inseparable part of personal marketing. Personal marketing is considered a relatively new field in human resources management, which emerged as a

---

* Corresponding author: martina.gogolova@fpedas.uniza.sk

separation from personnel management. A paying attention to human resources means not only hiring suitable employees and keeping them in the company, but also recruiting them for a common cause, creating favorable conditions for their work (Cheema and Javed, 2017), suitable working applications, professional growth and personal satisfaction, and building the enterprise as a human working community (Iskamto, D., 2021). The Companies that pay due attention and effort to personnel marketing and human resources are usually characterized by the higher loyalty (Saputra, F., and M Rizky Mahaputra, 2022).   and initiative of their employees, better work results, and a greater willingness of people to work harder for the benefit of corporate goals. Such businesses achieve greater profits and are better prepared for the future. A similar opinion is also held by Popkova et al. (2013) that the basic task of personnel marketing is to create an attractive image of the company as an employer. Another task, according to Esfahani et al. (2017), is to ensure an optimal amount of quality human resources. At the moment, the authors of e.g. Lazear and Oyer (2004), Lengnick-Hall et al. (2009), Dublebohn et al. (2009), Crowley & Bourke (2017). In Slovakia and the Czech Republic, e.g., personnel marketing is devoted to Nadanyiova (2016), Szarkova (2013), Olsovska et al. (2016), Myslivcova (2016) and Sukalova (2015). The goal of the aforementioned contribution is to bring the proposed methodology for measuring employee satisfaction closer to reality. This methodology can be used in companies in Slovakia that are interested in maintaining satisfied employees and a good name as potential employers in the labor market. In order to master the process of measuring and monitoring employee satisfaction, companies within the framework of personnel marketing in Slovakia, regardless of size and focus, should implement and adhere to the following algorithm of activities:

- specify who is a company employee,
- define employee needs and indicators of employee satisfaction,
- design and create questionnaires for measuring employee satisfaction,
- determine the size of the sample-a sample of employees,
- select an appropriate data collection method and conduct your own data collection,
- develop data evaluation procedures, including procedures for quantifying the level of satisfaction,
- use the results of measuring and monitoring satisfaction as inputs for process improvement.

2 Theoretical starting points

2.1 Personal marketing and its use in companies

Personnel marketing helps to recognize the needs and wishes of employees, both existing and potential, which can ensure the acquisition of a competitive advantage over other organizations Szarkova, (2013), Alniacik et al. (2012), Myslivcova, (2015). Huselid (1995) stated that businesses can adopt various HRM practices to improve the skills and quality of their employees and thus their competitiveness. A human resources should be understood as a potential source of efficiency growth and not as a cost to be minimized. Employees create the value of the company, so it is necessary to develop their skills (Budur, T. and Poturak, M. 2021). Israelsen and Yonker (2017) claim that personnel marketing focuses on the future and tries to estimate the real need for labor resources in advance. It takes into account business intentions and strategies. Companies with strong personnel marketing are at an obvious advantage, especially in terms of readiness to respond to competition and market

developments. Personnel marketing as the overall development of human potential expressed as the value of the organization.

2.2 The marketing mix in HR

Kovarova (2009) states that the classic marketing mix can also be used inside the company, not only in contact with customers. Good marketing starts inside the business, where the customer orientation turns into an employee orientation. Internal marketing can use marketing mix tools. The essence of personnel marketing is the use of marketing tools in the field of personnel. The classic marketing mix tools can be adapted to meet the needs of personnel marketing, and the marketing mix in HR can be assembled as follows (Szarková, 2013, Antosova, 2005):

1. Product (job) – the company tries to fill a vacant position with an offer from the labor market. It is possible to fill a job position and thus obtain a workforce from the internal or external labor market. The internal labor market consists of company employees who can be transferred to another job, and the external labor market consists of job applicants outside the company.
2. Reward for superior work performance This reward can be granted in the form of financial (salary, salary increase, bonuses) and non-financial rewards (promotion, praise, or various employee benefits). A set of forms and a reward system make up the company's reward strategy. An appropriate strategy can attract the necessary and high-quality human capital, stabilize current employees, motivate them to more demanding tasks, and support the growth of their qualifications.
3. Place (corporate culture) - defined as the workplace. When choosing a job, applicants often make decisions based on the corporate culture and image of the company. Corporate culture includes the substantive organization of the company, workplace relations, training and development of employees, recognized values, and what is considered good and bad in the company (Virgiawan et al. 2021).
4. Promotion (presentation of a job offer): it is a tool with which a company presents a job offer. This offer should be clear and comprehensible and should motivate and arouse sufficient interest among applicants. It contains all the information about the job and the requirements for the applicant, but also information about the company and the benefits it provides to its employees.

3 Results and discussion

3.1 Questionnaire items

The evaluation criteria in the questionnaire are based on marketing mix tools used in the field of HR. The questionnaire should be part of the annex to the company's internal guidelines and is made up of evaluated categories, which are listed in Table 1. The questionnaire contains an introductory address, an explanation of the purpose of the survey, and instructions for filling out the questionnaire. Each evaluation criterion is evaluated from the point of view of satisfaction and importance, with points from 0 to 3. Where 0 represents complete dissatisfaction and unimportance of the given criterion, and point 3 represents the highest possible satisfaction and the highest importance of the given criterion. At the end, there is room for possible comments and an increase in satisfaction from the employees' point of view.

Table 1. Evaluation criteria of employee satisfaction

	Evaluation criteria	Satisfaction				Importance			
		0	1	2	3	0	1	2	3
1.	Financial evaluation (wages, bonuses, rewards)								
2.	Non-financial evaluation (praise, company car, phone, laptop)								
3.	Possibility of career growth (training, courses, further education)								
4.	Catering at the workplace (choice of meals, quality of food)								
5.	Employee benefits (replacement time off, paid overtime, sports and cultural events for employees)								
6.	Working hours (flexible working hours, length of working hours, possibility of working from home)								
7.	Interpersonal relations in the workplace (work climate)								
8.	Organization of work (setting goals, division of work, method of achieving goals, etc.)								
9.	Communication between employees at the workplace (information about what is happening in the company)								
10.	Work environment (noise, temperature, cleanliness, lighting, equipment)								
Comments and suggestions for increasing employee satisfaction:									

Source: own elaboration

Data from the questionnaire is statistically processed and presented graphically. For the purpose of a better overview of the individual evaluated criteria, we recommend placing the resulting values (statistical average, mode, and median) of the evaluated criteria in the corresponding quadrant in the resulting matrix of employee satisfaction (see Fig. 1), which will provide a closer picture of the individual criteria.

		Satisfaction	
		high	*low*
Importance	*high*	I. IDEAL	II. PRIORITY SOLUTION
	low	III. EXCELLENT STATE	IV. RESOLUTION

Figure 1. The resulting matrix of employee satisfaction evaluation.

Source: own elaboration

3.2 Selection of a research sample

The basic file is determined from the records of the employees of the given company for the monitored year. The survey is anonymous and its completion is voluntary. We recommend a sample size (base set) of 95 % probability and 5 % variance.

3.3 Distribution, collection, and transmission of questionnaire data

It is methodologically correct and expedient to provide the questionnaire to the respondents on the day when the assessment takes place, together with instructions on the place of submission of the completed questionnaire, which should ensure anonymity. For data processing, it is necessary to designate an employee who meets the qualification requirements for working with data as well as material equipment such as software, a computer, a printer, and an internet connection.

3.4 Interpretation and publication of results

A person should be appointed to interpret the processed data, who will transfer the evaluated data into the form of outputs according to the purpose of use. It can also be the same person as the one who processes the data. Outputs can take the form shown in table 2.

Table 2. Use of information from employee satisfaction surveys

Purpose of use	Form of presentation of results	Publication of results	Frequency of publication
annual report	written document (electronically)	website	annually
information for management	written document	presentation of work meetings	monthly, quarterly, as determined
information for departments, sections	electronically	controlled documentation determined by quality management	continuously, taking corrective measures
public website	website, media	continuously	continuously

Source: own elaboration

The interpretation of the results should be entrusted to a person or several people who know the issue and can process the data in a form that will be clear, readable, and understandable for the individual subjects using the results of the satisfaction assessment. It requires knowledge of working with databases, graphic display of results, and interpretation knowledge. Designation of responsible persons and training is an important phase of the entire survey. In addition to the company's internal directive, which should be available to all interested parties and conveniently placed in the workplace, it is important to conduct regular training on survey procedures. It is also important to check the correctness of the implementation of surveys by employees of the quality department, or to the quality manager in the case of a functional quality management system. The implementation of the survey requires the identification of persons responsible for the following activities:
- distribution of questionnaires;
- briefing on filling in and submitting questionnaires;

- collection of questionnaires from the place designated for submitting the questionnaire;
- checking questionnaires and transferring data into electronic form; • data processing; and
- interpretation and publication of results.

4 Conclusion

Although personnel marketing is considered a relatively new field of management, businesses are increasingly becoming aware of its importance. Focusing on the employee, his qualities, education, and motivation are among the key elements of the competitiveness of companies in the market. Companies in Slovakia that pay due attention and effort to personnel marketing and employee satisfaction are generally characterized by higher loyalty and initiative from their employees, better work results, and a greater willingness of people to work harder for the benefit of company goals. Such businesses achieve greater profits and are better prepared for the future. This methodology can be used in companies in Slovakia that are interested in maintaining satisfied employees and a good name as potential employers in the labor market.

The uncertainties related to climate change and its damage

Abstract

Research background. Since the beginning of the industrial revolution, humanity has begun to change the earth's climate by releasing GHGs into the atmosphere: CO2, methane, nitrous oxide, and other fluorinated gases. The climatologists are almost unanimous: humanity will experience large-scale and, above all, very rapid climate change in the coming centuries. Some of these effects have already experimented in some parts of the world, by higher average temperatures, a rise in oceans level and an increased frequency of droughts, storms, hurricanes, and torrential rains. It might be too late to reverse the situation. We should replace old technologies based on fossil energy consumption, produce more clean energy and reduce our energy-intensive habits.

Purpose of the article: In this article, we will analyse the uncertainties about climate change and its damage and what are the terms of the debate on the need to act today.

Methods: Using descriptive and comparative analysis the paper reveals the risks of climate change for future generations and the impact on ecosystems and human activities.

Findings & Value added: The emergency of the situation imposes a quick response; Kyoto Protocol and Paris Agreement are the first steps to reach a global consensus but the scepticism will be always present in environmental debates.

Keywords: *climate change, greenhouse gases, fossil energy*

JEL Classification: *Q 01; Q 40; R5*

1 Introduction

The risks to climate change for future generations are severe and bring scientific, political, and ethical issues. These are issues of a new nature. Climate change is indeed the first large-scale impact on the global environment that is not rapidly and relatively easily reversible

---

*Corresponding author: iuliangole@yahoo.com

(IPCC, 2021; Brondizio et al, 2021). It raises questions that were not even imagined a few decades ago, in the sense of intergenerational equity; the attitudes towards future generations not only for centuries but maybe for millennia (Barnett et al.,2019; Mogos et al., 2021).

However, great uncertainties remain as to what exactly climate change will be and, above all, its consequences. These uncertainties first require a sustained research effort to better understand the nature of climate change that awaits us, its effects on ecosystems, and human activity (Radulescu et al., 2020; Bran et al., 2020). They feed into a very complex debate as to whether action should be taken now, how, and who should withstand the initial effort. From this debate, science today is only able to frame the terms and gradually tighten certain hypotheses. In the absence of scientific 'certainties', the decision-making process is therefore essentially a matter of policy, specifically a pragmatic understanding and application of the 'precautionary principle', as well as ethical considerations (Purnhagen et al, 2020).

To measure the current uncertainties, it is enlightening to start from what the apprehension of the problem should be if all the necessary information were available (Negescu Oancea, et al., 2020). The point is to move from a stabilized regime of the Earth's atmosphere, which was before the Industrial Revolution, to another stabilized regime, with a necessarily higher concentration of greenhouse gases (Kuzemko et al, 2016). Indeed, even if all emissions were stopped today - which is impossible - the already acquired increase in the concentration of greenhouse gases (for the concentration of CO_2 alone, we went from 280 ppm before the industrial revolution to 360 ppm now) would take centuries to absorb (Gergart and Ward, 2010). So the question is: what level of concentration is desirable to stabilize: 450 ppm or can we go up to 1,000 ppm (apparently this is the range in which most of the scenarios studied are located; ppm- parts per million)?

To answer this, we must first assess the consequences of a stabilized level of concentration on climate change, which themselves will take decades - and for some, centuries - to stabilize. The impact of climate change on ecosystems and human activities must then be assessed. If all this information is available, then one can, by reasoning which will be mentioned below, define the level of concentration not to be exceeded. It then remains to be determined the time profile of emissions, in the next century, which will make it possible not to exceed the concentration-ceiling level. In summary, we need to know the following sequences: what kind of emissions and what may be the stabilized concentration? How will impact climate change? Effects of climate change. For answers to these questions, researchers created analyses using powerful climate simulation models using information from a large number of disciplines, from biology to economics (Profiroiu et al., 2020).

However, there are currently great uncertainties regarding each of these sequences, so there is considerable uncertainty about the whole process. A very precise link between emissions and concentrations cannot yet be established, as uncertainties remain about the very complex "cycle" of carbon and other greenhouse gases released into the earth, the atmosphere, and the oceans. As for the link between stabilized concentration and climate change, the models give answers in a very wide range. For example, for a level of concentration stabilized at 450 ppm, the models give an average temperature increase range, in 2100, of 1.3 °C to 2.5 °C and 1.8 °C to 4 °C for the temperature stabilized (because warming will continue after 2100). The same ranges for a stabilized concentration at 1000 ppm are 2 °C to 3.5 °C in 2100 and 3 °C to 8.5 °C for the stabilized temperature (Goodwin et al., 2018). The geographical distribution of this average temperature rise, which is essential in the sensible analysis of effects, is even less well known. Finally, not much is known about the thresholds from which physical phenomena could be triggered that would cause a runaway of climate change (i.e., almost irreversible and nonlinear phenomena), such as the total melting of polar ice caps, the cessation of the Gulf Stream, the release into the

atmosphere, as a result of warming, of carbon stored in soils and methane stored in marine sediments.

2 Methods

Using descriptive and comparative analysis the paper reveals the risks of climate change for future generations and the impact on ecosystems and human activities. We confront the two extreme visions of what may be happening and what can be done in order to avoid the catastrophic consequences of global change. To have a better understanding we will analyse the global income gains of population and we will assess the projected annual CO2 emission and temperatures during time.

3 Results and discussions

3.1 Between the two extreme visions

As for the effects of climate change, the typology is known, but their assessment, especially monetary, can only be the subject of very crude estimates today - the main reason being that we are extended the effects of physical phenomena generated by climate change for that of social and economic developments. Indeed, it is not possible to assess the "damage" suffered by human societies without scenarios of what these societies will be in the next century.

It is therefore easy to conceive that, by combining the most favourable hypotheses, one can easily come to the conviction that it is more useful to wait and see more to act. But, conversely, it is conceivable that the combination of unfavourable assumptions cannot let us without reaction, as long as one cares about the future of humanity. We are navigating between two extreme options: few of us believe it is a controllable phenomenon in the future and others consider it an assured apocalypse if nobody acts very quickly. The fact is, at present, it is almost impossible to decide between these two extreme visions. Even though there is a vast majority of researchers and political leaders fighting against global warming, who are more visible on media, there are still some others who are convinced by the contrary – the former president of the U.S. Donald Trump (end maybe the future) is one of them.

Nevertheless, there are two things, however, that can be taken for granted:

1) Climate change, of a speed unknown in Earth's history (except perhaps that that followed after the meteorites collisions), will happen no matter what. This change will certainly not dramatically affect the men alive today, in the sense that the actual generation of people on earth will not be extinct. But it will require future generations of adaptation efforts (arguably geographically very unevenly distributed) that certainly include vast migrations. The only question then becomes: is it necessary to act now so that this effort is not too heavy to bear for future generations?

2) The long-term solution is technical. We have to slow down the use of carbon stored in fossil fuels, because burning this stock in its entirety, would lead to concentrations of greenhouse gases at levels where the likelihood of catastrophic damage in the coming centuries will not be negligible. Long before the depletion of fossil carbon reserves, it will be necessary to: a) find the technical means to supply humanity with non-fossil greenhouse gas (solar, liquid hydrogen, hydraulic, wind, biomass) and nuclear if the waste problem is managed properly); (b) provide cleaner technology or find ways to capture much of the CO2 emitted by combustion, since fossil fuels will

continue to be used during the transition period. But the questions are: When will this transition have to be completed? When should we firmly commit to it?

3.2 Should we act now?

This issue is at the heart of current controversies. For some, it would be a waste of productive resources to act now, because it will not cost so much for future generations to gradually adapt. If we want to help the currently poor countries, which will probably be the hardest affected, it would be better, for example, to help them eradicate poverty, solve the water scarcity, take malaria seriously or give them the means to cure AIDS. There are some people (Lomborg, B., 2001) generally called sceptical environmentalists, who express their opinions, by using statistical information from internationally recognized research institutes, and who criticised the way many environmental organizations make selective decisions based on the misleading source of information or scientific evidence. This type of reasoning supported first the delay of accepting the Kyoto Protocol and later the withdrawal of the U.S. government from the Paris Agreement.

Beyond all statistics and interpretations, we should have economic reasoning to try to understand the situation. Suppose we can assess in monetary terms the effort humanity will have to make in 2100 to adapt to the consequences of climate change if neither we nor future generations do anything before it. We should first assess that the 2100 generation is like ourselves and we should accept the burden and be willing to bear to avoid this damage for them.

3.3 Economic reasoning

But first of all, in 100 years the population will be richer than us (historically is proven that every generation contributes with added value to the global estate). Since there is no data older than 1940, we consider it appropriate to show available data for comparison.
Figure 1. Income gains in the last 70 years

Sources: CBPP calculations, 2020.

As could be seen, in the last 70 years, the real income gains grew up by almost 3 times (inflation adjusted), so it may be acceptable to assume that in 100 years, given the advance of the new technologies, the future generation will be at least maybe 5 times richer.

So it will be normal for our generation to accept to pay a fraction of this price, maybe 20%. Then, a few times richer, their basic needs will be more fully satisfied; so it is normal

for them to pay a higher price for the protection of their environment than we (especially the developing countries) are willing to do today so the maximal price which we should pay today should be lower, maybe 10%. It is then sufficient to assess the cost of the measures which, taken today, would prevent generations living in 2100 from having to bear colossal damage. If this cost is less than a certain threshold which we established as being roughly 10% of the total damage, and if, again, we treat them "like ourselves," so we must act now. Otherwise, it's better to shift the burden to them, because it will be "less costly" for them to act to repair than it is for us to act to prevent.

If now, we believe that the fate of future generations must be taken into account, but only to a certain extent, we go beyond the realm of economics to enter into the carrousel of ethics. Suppose that our concern for future generations (and therefore our preference for the present generation) translates into a decision such as we agree to take care today of only half the damage that our present inaction would cause, then the maximum cost we are willing to bear is reduced to 5%.

As we have seen above, we do not know precisely the cost of adaptation for future generations, the rate of economic growth for the future century, or the evolution of prices related to the environment, for future generations (Ekins et al, 2021). These are three parameters of an economic nature, more or less quantifiable but we do not have a very precise idea of the real level of damages, not to mention the level of an ethical preference for the present generation, which is more complicated to measure.

So while precise economic calculation leads to the problem of intergenerational choice, preventing or adapting, it certainly does not make it possible to decide today for lack of information. Consequently, neither the claims of sceptics nor those of the alarmists who urge us to act quickly and strongly can be based on objective data processed by economic calculation. But the necessary progress in robust data acquisition may not allow us to do so until it's possibly too late. We are therefore faced with an archetype of situations where it is necessary to reason differently, according to the precautionary principle.

3.4 Precautionary principle

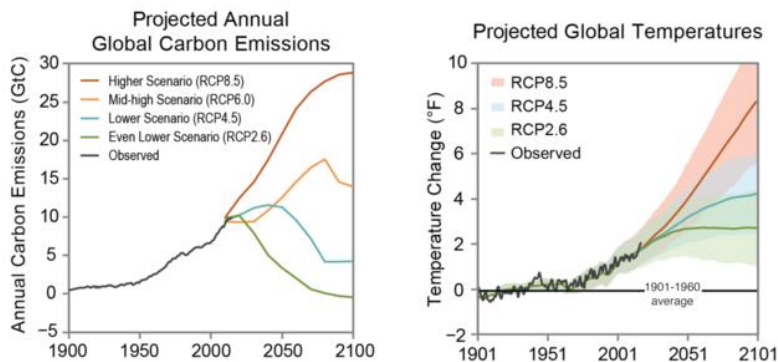
The application of the precautionary principle is justified when our current knowledge does not allow excluding extremely damaging and irreversible developments when they have already begun. Schematically, this assumes that we recognize the non-zero probability of nonlinear phenomena, such as threshold phenomena beyond which a sudden and irreversible acceleration of damage occurs.


Figure 2. Projected annual CO2 emission and temperatures

Sources: U.S. Climate Science Special Report, 2017.

If we consider the scenarios known as Representative Concentration Pathways (RCPs), for example, it means that 2025-2030 represents a threshold. If we don't diminish the CO2 emissions consistently then the average temperature will go irreversibly up. There is a minimum space of time for acting.

Years ago, the researchers told us that in case of inaction between 2000 and 2030, stabilizing the GHG emissions in 2050 would involve a huge effort to reduce emission flows between 2030 and 2050. Under these conditions, the cost to be borne for these reductions would amply justify (depending on the reasoning previous) to be undertaken now, spreading the effort over fifty years instead of twenty. By acting now, there is a risk of enduring "costly" efforts that are maybe too costly (in the sense that it would have been better to push them back in time). However, the cost of error in the event of good news will be significantly lower than the cost of inaction between 2000 and 2030, if extreme assumptions. In this case, the application of the precautionary principle is justified.

There is another argument, of a different nature, put forward by proponents of immediate action. If climate change policies are put in place now, they will result in a rise in the price of fossil fuel use and thus stimulate the search for non-polluting energy solutions, which will, one day, have to replace fossil carbon-based energies, and before their reserves are depleted (Moses et al, 2022). However, this argument is less strong and can be criticized: there is nothing to prevent it from being content, in terms of climate change policy, to launch a vigorous alternative energy research program right now. This was the position of the United States for a while: it is time to accelerate the research effort, but not yet to embark on costly emission reduction policies. Thinking of the future election, we have to consider we might see it again.

3.5 What type of policy to fight against climate change?

If, in the name of the precautionary principle, we believe that we must reduce emissions now, what policy should we adopt? Any policy to combat climate change can only result from an agreement between sovereign States. Such an agreement must have the following three characteristics:

1) Prohibit — or at least strongly dissuade (since no one can prohibit anything from a sovereign State) — the practice of the free passenger, since the preservation of the climate is a public good (when it is produced, no one can be excluded from its benefit and therefore everyone benefits, even those who have not contributed to producing it).

2) Take into account the current situation, which is characterized by an extreme diversity of emissions per inhabitant, not only between the poor and the rich world but within the rich world itself (the annual emissions per inhabitant in tons of CO2 equivalent are 15.5 in the United States, 11.5 in Russia, 5.13 in France, 7.38 in China, 9.7 in Japan, Worldometers, 2016).
In the next graphic we can see that the total CO2 emission is growing consistently, even in the last decade, in China, India, and Iran while other, more convinced and interested in reducing global warming consequences, effectively reduced their contributions.
Figure 3. Carbon dioxide emissions in 2010 and 2020 (in million metric tons)

Source: Statista, 2022.

Wanting to quickly reach objectives of convergence of emissions per inhabitant is certainly ethically defensible (since all people are equal, they have the same rights to use the planet), but politically unacceptable in the immediate future by many States.

3) Minimize, for a given emission reduction, the total cost. Indeed, once quantitative objectives have been set by a State, it would be absurd not to minimize the total cost of achieving these objectives. It would therefore be absurd to prohibit the countries which realize that the reductions are less costly at home to go beyond their objectives and sell this surplus to those for which it would be more costly to reduce emissions at home. Then "buying" these reductions from others (the CO2 certificates), will make the overall reduction the same, and the overall cost is reduced.

4. Conclusion

The emergency of the situation imposes a quick response; Kyoto Protocol and Paris Agreement are the first steps to reach a global consensus. The developing countries have to be convinced to be part of this common effort and not just free riders, but they need to preserve their development rights. More and more voices are therefore being raised to link climate negotiations to other agreement negotiations relating to the establishment of global governance, and in particular trade agreements within the framework of the WTO.

Europe must pursue and step up a policy to combat climate change based on four pillars: set an example by reducing its emissions through behavioural changes that allow the optimal use of technologies and develop a new one, less energy consuming; step up efforts to research techniques for replacing fossil fuels, as well as trapping and sequestering CO2; promote the adhesion of the major emerging countries by declaring without ambiguity that the countries that are currently rich must bear the bulk of the initial effort and do everything possible to

promote the adoption of the best techniques and practices by these emerging countries; work to link all international negotiations concerning "global public goods". Scepticism will be always present in environmental debates, it is important to fight it with strong scientific arguments that convince the world of the need to make decisions. Perhaps the breaking news about global warming, displayed in the whole media, without solid arguments and research, only creates a feeling of unnecessary panic among the population. Treating the subject more professionally would make some of us more attentive and less suspicious of this issue.

Motivation of Creative Employees in the Context of Globalization. IT Professionals in the EU

Svetlana Gribanova[1,*]

[1] IT Solution, Anninmuizas bulvaris 80-50, LV-1069 Riga, Latvia

Abstract

Research background: Information technology (further in the text IT) plays a special role in the knowledge economy and IT sector becomes key to the development of creative industries. When it comes to managing creative employees, the task of motivation, as a process of increasing job satisfaction, turns into the task of motivating an employee's creativity. This task requires more complex managerial decisions, formation of the motivational model that should simultaneously take into account personal creativity (abilities, talent), self-efficiency of the person (confidence in his abilities), intrinsic motivation and working conditions.

Purpose of the article: The aim of this article is to identify the opportunities and motivation factors of creative industries workers (using the example IT professionals in EU).

Methods: The research method is an online survey of IT professionals from EU countries (sample's size is 4200). The data obtained were analyzed using factor analysis and regression analysis, resulting in a motivation model that links intrinsic motivation, self-efficiency, and creativity of IT professionals

Findings & Value added: The results of the research showed the importance of intrinsic motivation for creative employees. Without intrinsic motivation, employees will not be creative, even with high self-efficacy and external motivation. At the same time, without self-efficiency, employees will not be creative, even if they want to do something useful for society and enjoy what they do. Finally, if the employee is confident in his abilities and is not afraid of punishment for failure, he will be the most creative in socially significant projects.

Keywords: *creativity; self-efficiency; IT professionals; motivation to work.*

JEL Classification: *A11; C14; F60; J28*

1 Introduction

The modern economy is often referred to as the "knowledge economy" (Coviello et al., 2017). The idea of the knowledge economy is that the growth and profits of companies depend more on factors such as knowledge and information than on factors such as labor and capital.

Information technology plays a driving role in the development of the knowledge economy and creative industries. The massive spread and development of communication technology helps to ensure the dissemination of information, facilitates access to information and the exchange of information. The development of Internet technologies has led to the creation and rapid growth of the number of platforms for the exchange of creative products. Communities of people with common interests, tastes, and worldviews are forming around these platforms. They represent spaces for self-expression, opportunities for meetings, contacts, exchange and consumption of creative products, and acquisition of new knowledge. All this helps the development of creative industries, creates conditions for marketing and management in modern conditions. Thus, the IT sector becomes key for the development of creative industries and the knowledge economy as a whole.

The products of traditional industries are usually evaluated by their practicality and functionality. In creative industries products are not evaluated by their functionality, but by their "expressive value", i.e. by their creativity, originality and novelty. The basis for the creation of expressive value is the creativity of employees. How creative employees are determining the success of companies operating in the creative market. The business model for companies in creative industries is the commercialization of expressive value, and the main task of management is to motivate employees' creativity, motivate their desire to develop their creative skills, motivate them to get new knowledge and new experiences (Betle, 2021). The problem of effective motivation is especially acute in the context of globalization, as the wider the labor market, the more offers qualified employees have. This paper examines the work motivation of IT professionals from EU countries.

Motivation to work is a very complex system, which is a combination of individual motives that motivate people to work (Vokoun et al., 2018). And this is the main task of company management. When it comes to managing creative employees, the task of motivation, as a process of increasing job satisfaction, turns into the task of motivating employee creativity. This task requires more complex managerial decisions, the formation of a more subtle motivational model, which should simultaneously take into account the personal characteristics of the employee (because creativity is primarily certain abilities, skills and talent), the self-efficacy of the person (i.e. his confidence that he is able to handle the tasks set), internal motivation (i.e. desire to work and show his creativity) and work conditions (organization of the work process, workplace characteristics, social environment). Even the most capable employee will not (or will not be able to) show his abilities fully if he works under strict control, surrounded by people who are not close to him (socially and professionally), if he performs uninteresting for him, routine work, and he has no sense of self-confidence.

Motivators in management refer to conditions that lead to increased job satisfaction, as well as increased employee productivity and self-efficacy (Nienhaus, Shrapnel, 2021). Locke's definition of what motivation is often used in management is "a pleasant or positive emotional state resulting from the evaluation of the result of work". It is this emotional state that is the ultimate goal of managers (Badubi, 2017). From a management perspective, motivation can be described as cognitive decision making to ensure that through initiation and control, employees take actions to achieve a certain goal. In doing so, they experienced job satisfaction and a desire to work even more creatively and efficiently.

Creativity is identified with the creation of a new product or new and original ideas. Those who have managed to translate their creative ideas into a tangible form receive not only recognition from others, but also great satisfaction from their work. Thus, creativity plays the role of one of the determinants affecting job satisfaction, because creativity is the effort used by a person to achieve their goals (Amabile, 1996; Rubenstein et al., 2018).

In order for an employee not to be afraid to be creative, not to be afraid to experiment and try new solutions, they must have confidence that they are capable of solving complex problems. In other words, the employee's self-efficacy is important.

Self-efficacy refers to the perception of an individual's ability to perform actions to exhibit certain skills (Bandura, 1986). Creative self-efficacy differs from self-efficacy in general because it focuses on the individual's beliefs about their own creative skills and their own creative potential (Chen, 2021). It is an individual's belief in their ability to create new projects or generate creative ideas (Amabile (1988)

Personal abilities (skills), motivation (in the form of job satisfaction) and self-efficacy (self-confidence), are elements of creative personality formation (Zahra, 2022). Thus, a motivational mechanism is formed: increased job satisfaction will influence increased self-efficacy, which indirectly affects individual professional skills. Individuals with high job satisfaction will continue to create ideas, designs, concepts, and creative products, resulting in increased self-efficacy.

Drawing on component theory of creativity, social cognitive theory, and social motivation theory, consider intrinsic motivation, self-efficacy, and social motivation as different motivational mechanisms underlying creativity. This is an attempt to develop a more nuanced theoretical approach to creativity motivation.

Over the past 30 years, research on creativity factors and on creativity motivation has been published quite frequently in leading journals, providing important data for researchers and practitioners. Even a highly creative employee may not display his or her abilities if he or she works in a company where the workflow organization negatively affects intrinsic motivation (Mahoney et al., 2021). However, it is important to remember that intrinsic motivation, unlike a person's creativity abilities and opportunities for its development, is more fluid. It is subject to the influence of the work environment, the influence of the organization of the work process (Amabile, 1988). In order to shed light on the different functions of the three motivational factors, it is necessary to consider how they may function in different situations, depending on the organization of the work process and the personal factors of employees.

Several important theoretical works emphasize that intrinsic motivation is the main motivational precursor of creativity (Pattonc, 2021). Also, the positive influence of intrinsic motivation on creativity has been shown in a number of empirical studies (Chen, 2020). In general, in contrast to self-efficacy as a source of motivation for creativity (Taylor, 2019), and in contrast to social motivation as a source of motivation for the usefulness of creative ideas, the authors argue that intrinsic motivation provides a unique motivational force for the desire to engage in creativity (Amabile, 1996; Deci, Ryan, 2012).

Thus, even when employees believe they can achieve results (i.e., they have high self-efficacy) and they are willing to propose new ideas beneficial to others (i.e., they are highly socially motivated), a lack of intrinsic motivation (i.e., lack of interest in and enjoyment of work tasks) will keep them from fully and persistently participating in these creative processes. A hypothesis can be formulated:

H1: Without intrinsic motivation, employees will not be creative, even when self-efficacy and social motivation are high. Statistically speaking, this means that by controlling for self-efficacy and social motivation, intrinsic motivation makes a unique contribution to employee creativity.

On the other hand, social cognitive theory and the studies that are based on this theory show that even if people enjoy their work (i.e., are highly intrinsically motivated) and are willing to focus on new ideas that are useful to others and the environment (i.e., are highly socially motivated) without sufficient self-efficacy (confidence in their abilities), the individual may still not achieve good creative results (Bandura, 1997; Taylor, 2019). This theory emphasizes that if people do not believe that they can achieve the desired outcome or prevent any negative consequences through their actions, they will not put enough time and resources into their work (Bandura, 2001).

From the perspective of component theory of creativity, increased self-efficacy results in employees cultivating a strong and resilient defense against failure, without which the creative process is impossible (Zahra, et al., 2022) and supports a focus on learning (Taylor, 2019). Therefore, even when faced with setbacks and risks, those with higher self-efficacy scores are less likely to abandon their efforts and agree not to engage in creative processes. In contrast, employees who suffer from low self-efficacy show less cognitive persistence and are more reluctant to continue discovering new knowledge, which prevents them from being creative.

A growing number of empirical studies show a positive relationship between self-efficacy and creativity (e.g., Devaux, 2017). Another hypothesis can be formulated:

H2: Without confidence in their abilities, an employee will not be creative even if they want to do something useful for society and others and enjoy what they do. That is, when controlling for intrinsic motivation and social motivation, self-efficacy makes a unique contribution to creativity.

Social motivation theory suggests that socially motivated employees will strive to develop ideas that are useful to colleagues, supervisors, clients, or customers (Betle, 2021). Social motivation encourages the individual to adopt the perspective of others and thus focus on discoveries that are useful to others (Pattonc, 2021).

At the same time, self-efficacy allows a person to be proactive, strive to achieve goals, and achieve creative results (Taylor, 2019). This behavior attracts people's interest in new ideas, unfamiliar things, and encourages new knowledge. Confident people are not afraid to propose new solutions, even if they turn out to be wrong or trivial.

Social motivation encourages people to consider the needs of others and attracts interest in ideas that are more useful to others. The above theoretical rationale suggests that in addition to intrinsic motivation and self-efficacy, social motivation can make a unique contribution to an individual's creativity by directing them to concentrate usefulness. Thus, the third hypothesis would be as follows:

H3: If an employee is confident and not afraid of punishment for failure, he or she will be most creative when completing socially relevant projects. In other words, when controlling for intrinsic motivation and self-efficacy, social motivation reaches the highest level of creativity.

2 Methods

Empirical data for testing the hypotheses formulated were obtained by online survey of IT professionals from EU countries. The sample size is 4200 respondents. The distribution of respondents by EU countries is shown in Fig. 1.
Figure 1. Distribution of respondents by EU countries

Source: author (2022).

The survey questionnaire included questions aimed at determining job satisfaction, assessing respondents' intrinsic motivation and social motivation, self-efficacy, and creativity. All of these variables are constructs and represent multiple variables. Table 1 shows from which observable variables the analyzed multiple variables are constructed.

Table 1. Construction of concepts

Intrinsic Motivation	Job gives me an opportunity to fully realize my skills and abilities	I get much pleasure from the work I do	Working in this company allows me to constantly improve my qualification and competence	This work inspires me. I want to perform all tasks as efficiently as possible
Social Motivation	In this company, I participate in realization of socially significant projects that help people, improve the environment, make the world better	In this company, I am among like-minded people, among people close to me in their values, culture and ideology	This company adequately assesses my qualification, skills and abilities	This company implements the principle of fair remuneration for each employee
Creativity	I like to work a lot		I can be very creative in my work	
Self-efficiency	I am not afraid to be without a job		I do any job as efficiently and effectively as possible	

Source: author (2022)

The partial least squares (PLS) method was used as the data processing method in this study. Partial Least Square (PLS) is a multivariate statistical method that compares multiple

dependent variables to multiple independent variables (Jogiyanto, 2011). The measurement model was used to test the validity and reliability of the measurement instruments, and the structural model was used to test causal relationships.

The PLS is a reliable tool for testing the predictive model because it can be used for small sample sizes and applied to the formative and reflective design. Another reason is that PLS can be used to develop theory.

In this study, causal relationships between variables were analyzed both for the entire sample and for each mill separately.

3 Result and Discussion

After collecting data from the questionnaires, the results were analyzed to determine the validity and reliability of each variable. Variables were considered valid if they corresponded to the scale of measurement of load, which is a minimum of 0.7 (Chen, 2021). The result showed that all measures of the variables creativity, creative self-efficacy, intrinsic motivation, and social motivation were valid. Reliability was tested through the composite reliability and Cronbach's alpha statistic, which was above 0.7 (Devaux, 2017). All variables in this study were found to be reliable.

Table 2 shows the influence of self-efficacy, intrinsic motivation, and social motivation on creativity. From the table, it can be seen that all of the variables analyzed have a significant effect on creativity.

The correlation between the tested constructs using t-statistics showed that the regression coefficient on the influence of intrinsic motivation on creativity is positive at the level of 0.239. The coefficient is positive, therefore, the higher the intrinsic motivation of the employee, the higher the creativity. Based on this result, the first hypothesis (H1) was confirmed.

Table 2. Inner Model Analysis Result (Structure Model)

Relationship	Regression coefficient	T-statistics	Significant
Intrinsic Motivation and Creativity	0,239	15,801	<0,001.
Self-efficiency and Creativity	0,509	17,903	<0,001.
Social Motivation and Creativity	0,209	13,644	<0,001.

Source: author (2022)

The highest regression coefficient in the model of self-efficacy influence on creativity. It is equal to 0.509 and has a positive value. I.e. the more a person is confident in his abilities, the more creative he is in his work. This result supports hypothesis (H2).

People's belief in their creative self-efficacy helps them achieve better results because they have strong motivation, a clear goal, stable emotions, and the ability to perform successfully. According Hennessey and Amabile (2010) analysis, when employees have good performance and achieve their goal, implicitly they have high job satisfaction. Job satisfaction will be achieved if it is supported by intrinsic motivation, extrinsic motivation (work environment, relationships with co-workers), and relationships of people in the organization. It can be concluded that these factors influence creativity and become a determinant of success. Human satisfaction can be achieved when there is an intersection between striving and achievement.

The regression coefficient value of the effect of social motivation on creativity is positive and is 0.209. The coefficient is positive, the higher the social motivation, the higher the creativity. T-statistic value indicates that social motivation significantly affects creativity. Based on this result, the third hypothesis (H3) is accepted, according to which social motivation has a significant impact on creativity of IT professionals.

Increased creativity affects the increase in productivity, which affects the skill of the employee. A person who manages to translate their creative ideas into tangible form will not only receive recognition, but also a sense of satisfaction with themselves. Therefore, people will continue to strive to create ideas, designs, creative concepts and products, which will also improve their creative skills.

There are studies that show that work complexity can contribute significantly to a person's self-efficacy because it cultivates professionalism (Bandura, 2001). Complex work requires a large cognitive investment. As job complexity increases, the individual needs to think through and choose from a variety of cognitive processes to respond to the challenges of the job. As a result, when employees perform complex work, they are more likely to increase their professionalism (Bandura, 2001).

In contrast, performing routine and simple work may cause employees to doubt their professional and creative abilities (Bitencourt et al., 2020). Even if employees handle routine work easily, they will rarely feel excited and satisfied with their work and may develop negative emotional states (boredom, dissatisfaction, frustration) (Kozlenkova et al., 2021).

PLS analysis conducted for each country separately showed that the identified patterns and formulated hypotheses are confirmed in all countries. Figure 2 shows the values of the regression coefficients in three models: the relationship between creativity and social motivation, creativity and self-efficacy, creativity and intrinsic motivation.
Figure 2. Relationship Creativity, Self-Efficiency, Social Motivation (Regression Coefficients)

Source: author (2022)

The results shown in Figure 2 show that in all of the countries that participated in the study, the strongest influence on IT professionals' creativity is self-efficacy, i.e., confidence that the professional can accomplish the task at hand. The relationship between self-efficacy and creativity is strongest in Germany, Britain, and Estonia. The weakest relationship between these concepts is in Romania, Hungary, and Bulgaria. Intrinsic motivation and social

motivation have significantly less influence on the creativity of IT professionals in all countries.

In their review of creativity research, Coviello and Kano (2017) suggested that it would be interesting to investigate how and why individualism might moderate the influence of predictors on creativity. Individualism fundamentally distinguishes some cultures from others and is the single most fruitful cultural dimension in cross-cultural management research (Mahoney et al., 2021).

Intrinsic motivation and self-efficacy correspond to norms of individualism rather than collectivism because individualistic culture emphasizes personal choice and the importance of competence (Barney et al., 2018). In an individualistic culture, people tend to see themselves as independent of their affiliated communities, thereby allowing their personal interests (i.e., intrinsic motivation) and confidence in their creative abilities (i.e., creative self-efficacy) to influence their behavior, including creative behavior. Thus, individualism can reinforce positive connections between intrinsic motivation, self-efficacy, and creativity.

Social motivation, reflecting an individual's desire to benefit others, is consistent with a more collectivist culture where people tend to view themselves as part of their affiliated communities and strive to achieve collective goals (Distel et al., 2022). Consequently, the positive relationship between social motivation and creativity may be weakened by individualism, which works against social motivation.

The data from this study partially support this assumption. Self-efficacy does have a stronger effect on creativity in countries with an individualistic culture. As for social motivation, the results of the study show that it is almost equally important for IT professionals from countries with different cultures.

The impact of a global change – the COVID–19 pandemic on commercial corporations in the Czech Republic from an accounting and tax Perspective

Jana Hakalová[1,*], *Marcela* Palochová[1], *Yvetta* Pšenková[1], and *Jiří* Slezák[1]

[1] VSB–TU Ostrava, Faculty of Economics, Department of Accounting and Taxes, Sokolská třída 33, 702 00 Ostrava, Czech Republic

Abstract

Research background: The COVID-19 pandemic in 2020 and 2021 has had a negative impact on most commercial corporations in the EU and around the world, making them highly vulnerable. It endangered a number of business entities in such a way that they had to close their business. From this perspective, it is crucial to understand the key factors and practices that entrepreneurs needed to ensure financial stability and maintain their business during the pandemic. At the same time, it is important to focus on the various forms of support and measures provided by the state in the period mentioned.
Purpose of the article: The aim of the paper is to analyse and evaluate the impact of global changes such as the COVID-19 pandemic in accounting and tax context, which all commercial corporations not only in the Czech Republic, the EU, but also around the world were forced to deal with, in the context of their financial situation, economic results and their business in general. The paper further deals with selected measures that were introduced in the Czech Republic in response to this situation, with the aim of mitigating the effects of the pandemic on businesses, and it also presents and analyses new interesting accounting situations that arose under these completely extraordinary conditions. It is also focused on selected tax matters in connection with the application of pandemic measures under the current the legislation in the Czech Republic within the business of commercial corporations in the years 2020 to 2022.
Methods: The methods of description, analysis, comparison, evaluation and deduction were used during the elaboration of this paper.
Findings & Value added: The analysis shows an understanding of key factors and procedures for dealing with emergencies such as COVID-19 pandemic.

1 Introduction

In early 2020, a global epidemic of coronavirus disease (COVID-19), which is caused by severe acute respiratory syndrome coronavirus, began to spread around the world. The first cases of the disease were confirmed in the Czech Republic on 1 March 2020. The Czech government, like most countries in the world, decided to introduce a variety of measures that limited economic activity in most sectors. Schools were fully closed; restaurants, hotels or some other business entities significantly reduced their services and and for that reason had to deal with a decrease in their sales. (Deloitte, 2022).

The closing or slowing down of the economy had an impact on the gross domestic product (GDP) of the Czech Republic. The Czech Republic's pre-global epidemic GDP level (Deloitte, 2022) should be reached by the end of 2022. The following Fig. 1 shows the GDP development of the Czech Republic from 2012 to 2022.

Note: * Estimate

Figure 1. Development of GDP in the Czech Republic 2012-2022

Source: ČSÚ (2022); Deloitte (2022), own processing

The Czech Republic experienced one of the biggest economic downturns in 2020 due to the global epidemic. Gross domestic product fell by around 10% year-on-year. The decline in GDP was significantly influenced by a reduction in exports abroad, which was caused, for example, by a decline in foreign demand. The investment activity of commercial corporations and households, which decreased in the period under review, also had a negative effect on GDP (Deloitte, 2022).

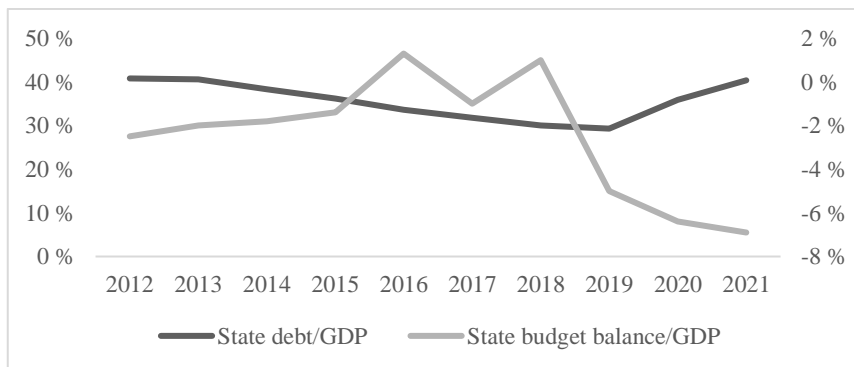
Fig. 2 shows the development of the national debt and the balance of the national budget to GDP from 2012 to 2021.


Figure 2. Debt and state budget balance 2012 – 2021 (in % of GDP)

Source: ČSÚ (2022), own processing

The national debt of the Czech Republic reached about 2.46 billion CZK in 2021 (40.4% of GDP). In 2020, it was about 2.5 billion CZK (35.9% of GDP) and in 2019 in the period before the global Covid-19 epidemic it was 1.64 billion CZK (28.3% of GDP). The balance of the state budget of the Czech Republic reached a deficit of about 419 billion CZK in 2021. In 2020 it was about 367 billion CZK, and again for comparison in 2019 it was 28 billion CZK (ČSÚ, 2022).

The Czech Republic's revenue was weakened by a decline in personal income tax revenue due to tax changes and a temporary waiver of value-added tax payments on electricity and gas in response to rising energy prices.

2 Methodology

Methods of procedure, description and comparison were applied in this paper. The authors' findings are summarized using the synthesis method.

3 Results

The COVID-19 pandemic in 2020 and 2021 had a number of negative impacts on the economy and the business environment of commercial corporations, regardless of the industry in which they operated. Business activity in some sectors has come to a complete halt, either due to the interruption of supplier/customer relations, lack of working capital or certain restrictions imposed not only by the government of the Czech Republic, but also by the governments of other countries around the world. Probable reasons for the economic decline were, in addition to the above, disproportionate loss of jobs, declining foreign exports, investment uncertainty, adverse effect on customer base, etc. (Hossain, 2021). Business corporations were forced to react quickly to this unprecedented and unexpected situation and to solve these impacts not only from the point of view of financial stability, but also to observe the continuous duration of the accounting entity (going concern), the principle of true and fair presentation or the principle of prudence, etc. COVID-19 pandemic affected not only large corporations, but also had a hard impact on small and medium-sized enterprises (SMEs), which had to face economic upheavals. Small and medium-sized enterprises faced various problems, such as a decrease in demand, cancellation of orders, liquidity crisis, delayed transportation, lack of raw materials and absence of employees. (Sarker et al., 2022). On the other hand, the pandemic positively affected the innovative activities of small companies (Urbanikova el al., 2021).

During the pandemic, commercial corporations projected a number of extraordinary accounting cases into their accounting and taxes, including solving tax aspects according to the rapidly changing provisions of the national accounting and tax legislation, and they were forced to deal with the impact of approved pandemic measures on their business. These included mainly the following extraordinary accounting and tax situations:

- provision of protective equipment to employees and testing of employees,
- costs associated with employees and working from home,
- providing interest-free loans to employees,
- analytical procedures associated with changes in the maturity of receivables and liabilities and the deterioration of payment morale,
- requests for the provision of subsidies to cover wage costs and their utilization,
- the creation and utilization of legal or other reserves for future expenses and incurred risks,

- creation of and accounting for adjustment entries in the event of a temporary decrease in the value of assets,
- estimated items for costs and revenues,
- impacts on financial statements, annual reports and non-financial reports (Hakalová et al., 2022).

It is important for every commercial corporation to manage its solvency and cash flow planning. Only a corporation that is able to pay its obligations on time creates the conditions for its continued existence and preservation. In case of a decrease in cash flow and liquidity of companies in an unexpected crisis, it was necessary to proceed urgently to solve these situations, for example, by postponing some payments, in the form of a loan, or cost optimization (Hakalová et. al., 2022).

During the COVID-19 pandemic, the government of the Czech Republic issued a wide range of measures and packages that reduced the effects of the pandemic on the business of small and large business entities, in most cases in the form of subsidy programs (Hakalová et al., 2020). As already mentioned in the introduction of this paper and in Figure No. 3, these were mainly Antivirus programs, compensation bonuses, Covid - Rent, Covid - Uncovered Costs, Covid 2021, Covid - Sport, Covid Gastro - Closed Establishments, Covid Fairs/Congresses, etc. During the audits of these subsidy options, problematic issues were solved primarily from a factual, but also a formal point of view. From a factual and time point of view, questions related mainly to various types of claimed cost items within the presented Amended Profit and Loss Statement were resolved, such as tax depreciation or adjusting entries. From a formal point of view, the actual verification of the Amended Profit and Loss Statement by the auditor in the context of missing data and prescribed requirements was a problem (KA ČR, 2022).

State expenditures of the Czech Republic increased in the mentioned years due to state subsidies provided to support the economy. The Fig. 3 below the total number of state subsidies paid to support commercial corporations and others in billion CZK.
Figure 3. Total number of state subsidies paid

Source: MPSV (2021); MPO (2022); Finanční správa (2021), own processing

The Antivirus program was used to optimize employment and protect jobs to cover labour costs. As of 10 August 2021, approx. 50 billion CZK was paid out and more than 70 thousand commercial corporations were supported (MPSV, 2021). The development of the unemployment rate shows that it decreased until 2019, while from 2020 there is a slight increase. Covid-19 certainly has an impact on the labour market. Redundant jobs may be

abolished, unqualified employees may be dismissed (Dvořák et al., 2020) and the influence of Industry 4.0 is also increasing (Hedvičíková and Kozubíková, 2020).

The Covid Rent program served entrepreneurs to pay part of the rent if they were obliged to close the retail sale of goods and the provision of services. As of 25 March 2022, approx. 9.8 billion CZK was paid out in a total of 3 calls (MPO, 2022). The Covid Uncovered Expenses program was used to reimburse entrepreneurs operating in selected sectors (such as organizing sports or cultural events). As of 25 March 2022, approx. 8.9 billion CZK was paid out (MPO, 2022).

The Covid 2021 and Covid Gastro program was used by entrepreneurs to maintain their business activity (operating costs). As of 25 March 2022, approx. 6.6 billion CZK was paid out respectively 3.2 billion CZK (MPO, 2022).

However confusing and stressful the situation during the COVID-19 pandemic might seem, from an accounting point of view it was necessary to respect long-known and valid accounting principles and proceed using principles and proceed according to the set rules, and based on new relevant information capture and also present faithfully and fairly current negative situation and impacts (Hakalová et al., 2016). As a result, accounting information can then in turn support policy makers to introduce various aid mechanism (Buchetti et al., 2021).

As for the financial reporting, it became very important during the pandemic to comply with the principle of the going concern according to Section 7 (3) of the Act No. 563/1991 Sb., on Accounting. This is not only a legal duration, but primarily an economic duration for the near future. This principle is very important and is always verified by the auditor for at least another 12 months after the balance sheet date and commented on not only in the notes to the financial statements and in the annual reports of corporations, but also in the reports of auditors. For a number of commercial corporations, this principle was threatened by the pandemic (MPSV 2021; MPO, 2022).

3. 1 Significant changes in income taxes

The nationwide measures that were taken due to the coronavirus epidemic brought about a number of restrictions in the business environment and had a negative impact on most business entities, i.e. legal persons and individuals. For this reason, a number of important measures in the area of direct taxes have been adopted over time.

During 2022, there was an amendment to the road tax, the subject of which are all motor vehicles that are used for business. The road tax has been completely abolished for passenger cars and vehicles up to 12 tonnes. The road tax for goods vehicle over 12 tonnes maximum weight has been substantially reduced. However, significant changes have already occurred since 2020, mainly in the area of income tax.

An important change in the Act on Income Taxes which can help to obtain funds for further investments in the business earlier than usual and thus improve the cash-flow of the business entity, **is the retroactive application of tax loss carry back as an item deductible from the tax base. namely for the two tax periods immediately preceding the tax period or the period for which the tax return is submitted for which the tax loss is determined.** Until 2020 in the Czech Republic, a taxpayer could deduct a tax loss from the tax base only in the following periods. The basic principle in claiming tax loss was that the tax entity had to show a positive economic result in subsequent years, i.e. a profit, in order to be able to use the loss for previous periods. If no profit was made in the next five tax periods in which the tax loss could have been claimed under the law, the taxpayer has lost the possibility of claiming the tax loss from previous years. Thanks to the introduction of the of retrospective claiming of tax loss, income taxpayers in the Czech Republic could claim any tax loss

reported for 2020 in their tax bases already for 2019 and 2018, but in a limited aggregate amount not exceeding 30 million CZK. Thus, in the form of a refundable overpayment, the income tax payers were able to recover the funds for the tax paid or part thereof for that tax period. The option to claim tax losses retrospectively is one way to encourage domestic companies to maintain employment, stay healthy and continue to do business. It is a recommended institute that is now in operation in many countries around the world. (Albitar, 2021). As a result of claiming a tax loss retrospectively up to a maximum amount of 30 million CZK tax revenues of public budgets will decrease. According to the calculations of the Ministry of Finance of the Czech Republic, this is expected to amount to approximately 32 billion CZK for 2020 and 2022, but it is by this shortfall that tax revenues will increase compared to the current situation between 2022 and 2025, when companies and entrepreneurs would claim the tax loss, they would have incurred in 2020 and 2021 (MF ČR, 2022). Claiming tax loss retrospectively is also possible for entrepreneurial individuals. For more information on aspects of personal income taxation (Krajňák, 2021).

Another significant change in income taxes with effect from 1 January 2020, there was a renewal of the category of previously used extraordinary tax depreciation in 2009 and 2010 for selected tangible property for a taxpayer who is its first depreciator. This is property classified in the first and second depreciation group. The entry price for tax depreciation of tangible assets was also increased from 40,000 CZK to 80,000 CZK and the tax category of intangible assets was abolished. This measure abolished tax depreciation of intangible assets. Tax depreciation of intangible assets corresponds to the accounting depreciation that accounting entities establish in their accounting depreciation schedules.

For tangible asset classified in the first depreciation group, the taxpayer may write off 100% of the entry price over a 12-month period without interruption on a straight-line basis. For tangible assets classified in the second depreciation group, the taxpayer may depreciate 100% of the entry price over 24 months, with depreciation applied evenly for the first 12 months up to 60% of the entry price of the tangible asset and depreciation applied evenly for the immediately subsequent 12 months up to 40% of the entry price of the tangible asset. For the four other depreciation groups listed in the appendix to the Income Tax Act, extraordinary depreciation cannot be used.

Technical improvements of tangible assets depreciated by extraordinary depreciation does not increase their entry price. The completed technical improvement is classified in the depreciation group in which the tangible asset on which the technical improvement is carried out is classified and is depreciated as a separate tangible asset. Extraordinary tax depreciation cannot be discontinued, and the discontinuation of tax depreciation is and will continue to be a common tool for effective cost recovery in cases of tax loss or very low tax base. The taxpayer is not required to use the extraordinary tax depreciation. In case of a low tax base, the taxpayer may decide, for example, to use the straight-line method in the year of acquisition or to discontinue depreciation.

Extraordinary depreciation, however, can significantly reduce the high tax base and thus bring savings in corporate or personal income tax over time. The negative effect caused by the faster claiming of tax expenses in the form of extraordinary depreciation, which can be expected, could in the future be a possible increased rate of corporate or personal income tax, applied to the taxpayer's future tax base, which has already been reduced in previous years due to the extraordinary depreciation already applied. As extraordinary depreciation is determined with an accuracy of months, the benefit associated with the application of extraordinary depreciation may not be shown in the first taxable period, for example for assets acquired towards the end of the tax year. (Hakalová et al., 2022)

The tables below provide an approximate calculation of the corporate income tax savings for a commercial corporation in each year assets are depreciated. Table 1 shows the saving using conventional accelerated and straight-line depreciation, and Table 2 shows the

extraordinary depreciation. A machine was acquired by a commercial corporation that is a VAT payer in November 2020 on credit for a purchase price of 1,200,000 CZK excluding VAT and is under the Income Tax Act classified in the first depreciation group.

Table 1. Accelerated and straight-line tax depreciation and corporate income tax savings

Depreciation year	Accelerated depreciation in CZK	Corporate income tax savings in CZK (if depreciation calculated by the taxpayer is used)	Straight-line depreciation in CZK	Corporate income tax savings in CZK (if the entire depreciation calculated by the taxpayer is used)
2020	400,000	76,000	240,000	45,600
2021	533,334	101,333	480,000	91,200
2022	266,666	50,667	480,000	91,200

Source: author's own calculations

Table 2. Extraordinary tax depreciation and corporate tax savings

Depreciation year	Extraordinary depreciation in CZK	Corporate income tax savings in CZK
2020	100,000	19,000
2021	1,100,000.	209,000

Source: author's own calculations

The calculations show that the savings on income tax can be significant when using extraordinary depreciation and can thus be considered an effective instrument of state assistance to business entities in the area of direct taxes. However, according to the analysis carried out by the Ministry of Finance of the Czech Republic, the institute of retroactive application of tax losses and even the possibility of applying extraordinary depreciation were hardly used by tax entities during 2021, contrary to expectations. Initially, the negative impact on the state budget for 2021 was projected at 18.7 billion CZK. It can also be concluded from the analysis of collections that the sectors most affected by the crisis and anti-epidemic measures do not usually generate such a tax liability that its shortfall would significantly affect the total amount of collections to the state budget (MF ČR, 2022).

4 Conclusion and discussion

The Covid-19 pandemic had significant negative impacts on the economies of all countries of the world, on the business environment of individual countries and, of course, it also had very negative impacts on people's health. Like other countries, the Czech Republic had to take a number of measures to mitigate these negative impacts in all of the above areas. This paper, however, focuses only on the impact of the COVID-19 pandemic on commercial corporations from an accounting and tax perspective in connection with the application of pandemic measures under current legislation in the Czech Republic In the area of accounting, commercial corporations had to deal with a number of extraordinary accounting cases, which involved, among other things, the use of various state subsidy programmes. At this time, it was more than a necessity to consistently use the applicable accounting principles and guidelines, which also had to be presented correctly. It was mainly an honest and faithful capture of the current negative situation and the effects in commercial corporations. At the time of the pandemic, it became absolutely necessary from the point of view of financial reporting to respect the principles of the assumption of continued existence of the accounting entity (going concern). On the other hand, properly reported accounting information can help

the state implement effective aid mechanisms. In the Czech Republic, it was possible to use a number of subsidy programs for such assistance. In addition to them, the state also introduced various measures in the area of taxes, which related to both direct and indirect taxes. The paper tries to point out the most important measures in the area of direct taxes, such as the possibility of claiming a tax loss or using the category of extraordinary tax depreciation. Although the state assumed that the use of these tools would have significant negative impacts on the state budget, it was found from the analysis of the collection of the state budget that commercial corporations did not generate such a tax obligation in 2021 that its shortfall would fulfil the expected negative impact on state budget revenues. The aim of all the measures taken and the introduction of subsidy programs by the state was to ensure financial stability and the maintenance of the activities of business entities during the pandemic.

The development of the labour market and its dynamic models in the context of Industry 4.0 and the current economic crisis in the Czech Republic

Martina Hedvicakova[1,*]

[1] University of Hradec Kralove, Faculty of Informatics and Management, Department of Economics, Rokitanského 62, 500 03 Hradec Kralove, Czech Republic

Abstract

Research background: Since 2001, when Industry 4.0 was first mentioned, there has been a very rapid expansion of this initiative. Given the current economic situation and the increasing pressure of globalization at the beginning of the twenty-first century, the onset of this fourth industrial revolution seems inevitable. Since 2019, however, the markets have been affected by the Covid 19 pandemic, as well as the war in Ukraine, which caused shortages of basic production raw materials, companies are forced to look for new ways to satisfy the needs of customers. These aspects caused the onset of the economic crisis to accelerate.

Purpose of the article: In order for manufacturing companies to survive in the competitive market, they must constantly look for new ways to increase their competitive advantages. The emphasis is on the price, but also the speed of production. One possibility is Industry 4.0 and the substitution of labour with capital. Companies will achieve higher work productivity, and higher efficiency and execute orders just in time. However, this substitution also brings with it an increase in unemployment.

Methods: Substitution of labour by capital will be modelled using Stella Professional software. Dynamic models will calculate the return on the investment period. Data will be obtained from international databases and the International Federation of Robotics.

Findings & Value added: Dynamic models of the substitution of labour by capital will be created. The models will calculate the return on investment for 15 years ahead, and company managers will be able to decide on the basis of them whether to implement the capital investment and especially at what moment.

Keywords: *Stella Professional; substitution, robot, effectiveness, payback period*

1 Introduction

In recent years, there have been very rapid and dynamic changes. First, the entire world was hit by the Covid 19 pandemic in 2019 and the markets had to react. Industries were affected to varying degrees. Subsequently, a war conflict arose in Ukraine, which disrupted supply-customer chains and slowly resulted in an energy crisis. These aspects led to the search for new possibilities for increasing production efficiency. It is also necessary to produce and deliver the goods to customers on time. The vision (Meindl et al., 2021) of Industry 4.0 is increasingly gaining ground on the market as a concept that goes beyond the area of Smart Manufacturing and thus creates opportunities for synergies with other related fields. The digital transformation under Industry 4.0 is immensely resource-intensive and complex. Smaller manufacturers must have specific capabilities such as change management and digitalization strategic planning capability to reach a certain degree of information, digital, operations and cyber maturity (Ghobakhloo & Iranmanesh, 2021). The requirement of increased productivity, improved flexibility and resilience, and reduced cost in Industry 4.0 manufacturing calls for new paradigms that comply with the changing of production and operations management (Guo et al., 2021).

Collaboration of humans and robots in close proximity in a single work space is a stimulating feature of Industry 4.0. The main field of application of robotics is industry. Technologies contributing to the improvement and automation of processes are constantly improving. (Galin & Meshcheryakov, 2019).

As part of the implementation of Industry 4.0, the interconnectedness and relationships of all relevant stakeholders, i.e. private and state companies, the state, trade unions and employers' associations, are often ignored. However, only by taking these connections into account can individual countries prepare for the social and economic impacts of the current trend of digitization and automation. In the future, industry, science, research and innovative new technologies will increasingly be connected, which needs to be approached comprehensively if the transition to Industry 4.0 or Industry 5.0 is to be successful (Maresova et al., 2018).

The study (Popelo et al., 2021) dealt with the influence of digitization on changes in forms of employment and the labour market in modern conditions in Ukraine. It is documented that digitization processes directly (both positively and negatively) affect the change in forms of employment and the range of occupations on the labour market, as well as the change of job. In the process of digital transformation in the economy, there is: reduction of personal costs of employers; the spread of non-standard, informal employment (electronic freelancer, electronic outsourcing, job initiation); allow employees to manage their working hours; increasing unemployment and imbalance of supply and demand in the labour market; reduction in the productivity of enterprises as a result of reduced productivity of workers with non-standard forms of employment, possibly with a negative indirect impact on productivity.

New technologies will enable manufacturing companies to increase labour productivity, increase the quality of production, just in time, but above all will solve the labour shortage on the labour market. Substitution of labour with capital is an option to increase the overall efficiency of production, but it can also be the only way to satisfy the demand of your customers.

2 The goal of the paper and methodology

The aim of the article is to create a dynamic model of the replacement of labour with capital in the Stella Professional software. This model will calculate for 15 years ahead the payback period of investment in robots and simulate the development of robot prices and labour costs for this period. The benefit of these models is the ease of use for the decision-making

processes of small and medium-sized enterprises. This model will be used for the initial decision-making on the implementation of the investment in the automation of production. Input data for calculating the payback time of the robot as calculated on the basis of the IFR statistical yearbook (International Federation of Robotics, 2022), Panorama of Czech Industry (The Ministry of Industry and Trade of the Czech Republic, 2018), the Czech Statistical Office (Czech Statistical Office, 2022) and information from manufacturers of industrial robots (e.g. KUKA, ABB, Staubli).

First, the key variables on the labour market in the Czech Republic and their development since 2011 will be described. Subsequently, models will be created for the substitution of labour with capital, which will calculate the payback period of the investment in a fifteen-year period.

IFR (International Federation of Robotics, 2022) members use the definitions contained in the international standard ISO 8373. "An industrial robot" is defined to be an "automatically controlled, reprogrammable, multipurpose manipulator, programmable in three or more axes, which can be either fixed in place or mobile for use in industrial automation applications."

The payback period is a widely used capital budgeting tool in the analysis of investment projects. It has come under fire for not considering all project streams in the current valuable context (Boardman et al., 1982). For the purpose of quick calculation of the payback period, Stella Professional software will be used, which enables the creation of dynamic models. As a result, the payback period takes on a new identity that far surpasses the objections raised against it in the past (Boardman et al., 1982).

Payback periods (in years) were calculated through comparing the cumulative annual monetary savings in successive years with the total investment (initial installation cost + cumulative operation and maintenance costs in successive years) of the RWH system. Net savings for a year is the annual monetary savings subtracted by the annual operation and maintenance costs. Net savings under different scenarios for the successive years were converted to equivalent net present value (NPV) as per the following equation 1 (Imteaz et al., 2021):

$$\text{NPV of Savings} = \sum n=1 n AS \, (1 + r) \, n \qquad (1)$$

where "AS" is the net annual savings for a year, "r" is the rate of return and "n" is the number of years since installation (Imteaz et al., 2021).

3 Results

3.1 Developments in the labour market and key macroeconomic indicators in the Czech Republic

The unemployment rate has been decreasing since 2014 to the current 2.8% in 2021 in the Czech Republic. The unemployment rate is thus below the natural rate of unemployment. On the contrary, the inflation rate has been increasing for the last three years and in 2021 it reached the level of 3.8%. However, it began to rise progressively in 2022, and in August 2022 the inflation rate reached 11.7% and the CPI 17.2%. Although the Czech National Bank increased interest rates, inflation increased. GDP responded to the onset of the Covid 19 pandemic and in 2020 GDP fell by -5.5%. In 2021, the economy recovered and GDP reached 3.5%. The following Figure 1 shows these key macroeconomic variables.
Figure 1. Key macroeconomics indicators in % in the Czech Republic

Source: (Czech Statistical Office, 2022), own processing

From the point of view of the substitution of labour by capital, the key values are the average wage. The average wage responded to the development of the gross domestic product and inflation. It grew until 2018, and from 2019 there was a decrease to the current 4.8% growth of the nominal average wage (see Fig. 2). The average wage for the second quarter of 2022 grew by 4.4% and the real wage fell by 9.8% due to rising inflation. The gross average wage was 40,086 CZK for the second quarter of 2022 in the Czech Republic (Czech Statistical Office, 2022)
Figure 2. Average gross wages and salaries (nominal and real) in % in the Czech Republic

Source: Czech Statistical Office (2022), own processing

Due to the excess of labour demand over labour supply, the labour market is experiencing an increase in labour costs that do not correspond to the economic cycle. The pressures of trade unions and employees reacting to rising inflation and falling real wages are manifested here. Due to the lack of workers on the labour market, companies are forced to increase personnel costs. At the same time, material costs and especially energy costs are increasing. For these reasons, companies are forced to look for ways to increase their efficiency. One of the possibilities to increase labour productivity is investment in robotization and automation of production. The Industry 4.0 initiative, which was created in 2013 in Germany, also emphasizes the importance of new information and communication technologies in production.

This market situation will be modelled in the following chapter. It is assumed that in order to remain competitive, companies must invest in new technologies. The models can be used primarily in the processing industry of the Czech Republic and in small and medium-sized enterprises. As a result of the introduction of Industry 4.0, there could also be a loss of jobs on the labour market.

3.2 Dynamic models in Stella Profession

Model creation and simulation of system dynamics is implemented in the Stella Professional program. First, the level and flow diagram will be used. After specifying and supplementing the decision rules, he will be able to implement simulations.

The diagram is based on four levels – Price of labour of planned employees, Wages substituted employees, Price of robot and Installation costs of robots.

These elements were chosen because they are considered to be the most significant within the modelled problem. Figure 3 shows the four layers with their respective sources and drains that ensure the change of state over time. Both: Price of labour of planned employees and Wages substituted employees; there is a constant two-way change over time, as new jobs are created and others disappear. Employees also enter and exit the work process. On the contrary, with Price of robot and Installation costs of robot, only increments are calculated. Because, even in the long term, technology (robots) becomes obsolete and is depreciated, but the model assumes, within the framework of maintaining the competitiveness of production, their replacement after the end of their useful life. This is a simplification of the model. The need for repairs and modernization is also not considered here. An analysis of the development of the price of robots showed that the price of robots decreases over time and increases with skills and capabilities. Installation costs are also falling due to the increasing number of installed robots. The other diagram elements are auxiliary variables.
Figure 3. Diagram of levels and flows

Source: autor (2022)

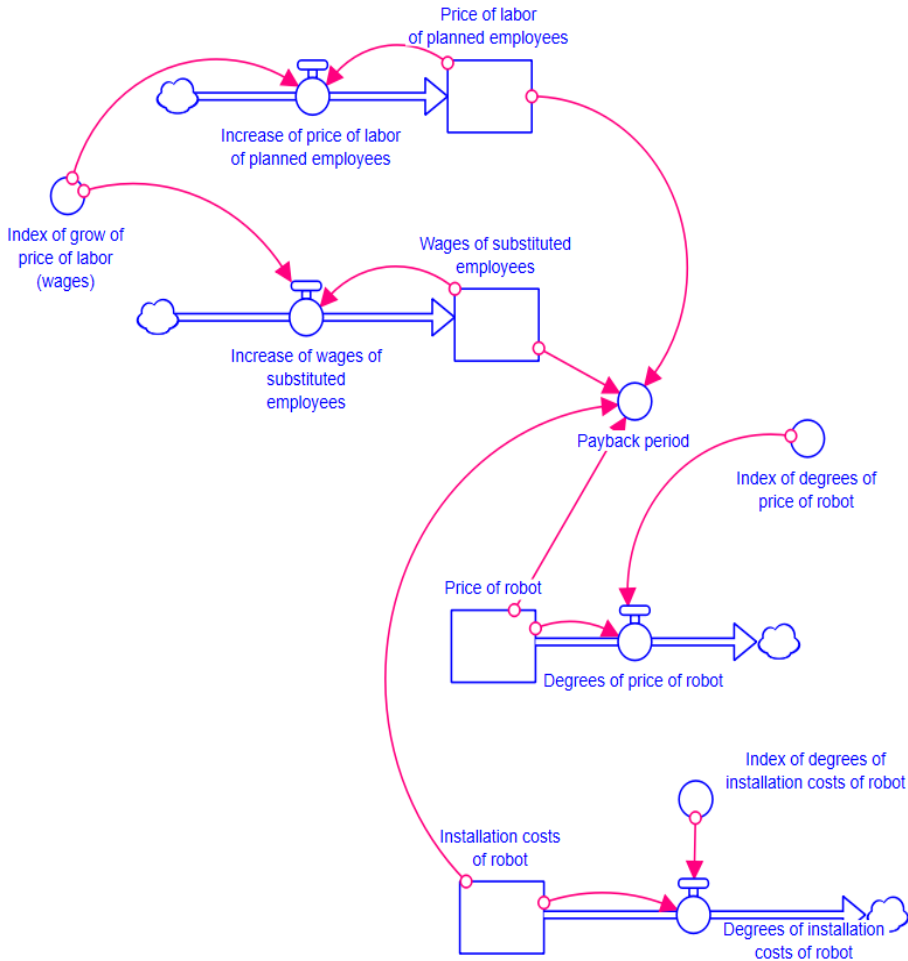
The following figure 4 shows the main variables and their dependence between the input values "Price of labour of planned employees", "Wages of substituted employees", "Price of robot" and "Installation cost of robot" and the effect of this dependence on "Payback period". Individual input variables can undergo changes in their amount over time using indexes and this will of course affect the value of the payback period (Hedvicakova, 2021).


Figure 4. The model of payback period

Source: (Hedvičáková, 2021), own processing

The following Figure 5 shows the simulation of the development of the payback period for 15 years. Figure 5. shows that the payback period decreases over time and for this reason it is more efficient to postpone the investment. However, managers must take into account I nan and increasing competition and whether the firm is able to meet its obligations, because automation can allow it to produce more products at a higher quality.
Figure 5. The payback period for 15 years

Source: Hedvičáková (2021), own processing

Figure 6 shows the development of wages of substituted employees, which are increasing over a fifteen-year period. Because wages increase over time, but robot prices are constant or even slightly decreasing, the payback period decreases. It is also necessary to take into account whether the price of robots is constant or slightly decreasing over time, but the skills and capabilities of robots are constantly increasing.
Figure 6. The development of the wages of substituted employees and price of robot

Source: Hedvičáková (2021), own processing

3 Conclusion and discussion

The development of key variables in the labour market of the Czech Republic forces the management of small and medium-sized enterprises to search for new ways to increase their efficiency and competitiveness. One possibility is production automation. Based on the created model, it is possible to calculate the payback period and simply modify the model by key variables. Another possibility of the model is the extension, for example, of depreciation or energy prices, which are currently the most discussed costs.

The current economic situation presents an existential challenge for many businesses. The adverse effects of pandemics, epidemics, economic crises, natural disasters on various macroeconomic variables are not a new phenomenon and are supported by a number of literature, e.g.(Fasanya et al., 2021; Shaikh, 2021; Su et al., 2022).

Growth through innovative business models using the example of the social economy

Michael P. Heide[1,*]

[1] Babeş-Bolyai University Cluj-Napoca, Faculty of Economics and Business Administration, Department of Marketing, Romania

Abstract

Research background: Organizations are in the VUCA world and need to evaluate their traditional business models. Megatrends and new digital technologies are changing the established business models of many companies. Further developed, disruptive business models or business model innovations characterize the diverse spectrum of modern, innovative business models. The global corona pandemic, which broke out at the beginning of 2020, is considered a catalyst for the digital transformation of organizations – also in the social economy, to ensure innovation and competitiveness.

Purpose of the article: This research contribution aims to show organizations how organizational change – triggered by (disruptive) technologies and changed market conditions - can be designed. A structured business model is the key to success. The focus is on measuring customer satisfaction as a basis for optimizing stakeholder orientation.

Methods: The author chose the quantitative research approach. The two satisfaction constructs CSAT and NPS were operationalized using questionnaires.

Findings & Value added: In times of disruptive change, serious effects on established business models will occur more and more frequently and strategically challenge organizations. Organizations need to understand the most important drivers for their business as they have a significant impact on the success of the business model. Digital support for the customer when using the product or service is essential these days. At the same time, the holistic understanding of the customer influences the organizational portfolio design of the socio-economic organization.

1 Introduction

Many organizations in the VUCA world are in the midst of a fundamental change, which is being shaped by digitization and changed lifestyles, as well as by so-called real-time competition. What began with the digital transformation in the context of the megatrends is being reinforced by the SARS-CoV2 virus (Kröger & Marx, 2020; Ulrich et al., 2021). The associated economic effects require a strategic, innovative rethinking of organizations (Heide et al., 2021). Holistic communication influences the positive acceptance of business decisions, especially at the operational level (Kreidenweis, 2018). The development of the corporate landscape is shaped by changing framework and environmental conditions - new business models are emerging (Brunetti et al., 2020; Kröger & Marx, 2020; Müller, 2019). Stakeholders are increasingly becoming the focus of innovative thinking and action (Brunetti et al., 2020; Rintamäki & Saarijärvi, 2021; Tampio et al., 2022; Thömmes, 2022) by (social economy) organizations.

The term "business model" is now an integral part of any organization in the social economy and is interpreted in different ways. No prose on the subject of "strategy" dispenses with the inflationary use of the term business model. Volatile markets and changing expectations and needs of stakeholders pose key challenges for management (Müller, 2019). Due to the dynamism of (global) competition, innovations have become immensely important, especially when modeling sustainable business models that are intended to offer customers added value (Brunetti et al., 2020; Müller, 2019). The structure of the financing also characterizes the operational growth opportunity.

The theoretical concept is provided by the value-based business model approach, which must be relaunched due to changed framework conditions. Technological progress in communication opens new possibilities for interaction – the customer becomes a co-developer of products and services (Karlsson, 2022; Kucia et al., 2021; Staudacher, 2021). Furthermore, modifications in the earnings mechanics can be observed, also in the context of the platform economy.

In the meantime, online platforms have established themselves as important players in the market. This creates new opportunities for organizations to generate added value for stakeholders. Modularization and intelligent, data-based services provide the answer to a meaningful, pragmatic design of portfolios (Kreidenweis, 2018; Kucia et al., 2021). (Disruptive) technologies form new business models, which at the same time lead to a new value proposition of the organization. In addition to monetization, it is important to understand the customer journey of a customer with all touchpoints as an essential basis of modern business models in the age of digitization (Brunetti et al., 2020; Rintamäki & Saarijärvi, 2021; Tampio et al., 2022; Thömmes, 2022).

The aim of the research contribution is to show social economy organizations how organizational change can be designed. The focus is on measuring customer satisfaction in order to ensure the continued existence of the organization in the long term. Best practice approaches should help to maintain the organizational ability to act in post-corona times and to promote qualitative growth by modeling sustainable and stakeholder-oriented business models.

2 Literature review

At the end of January 2020, the spread of the infectious disease COVID-19 (corona virus) led to the World Health Organization declaring a global health emergency, which had drastic effects on all companies worldwide (Nemțeanu & Dabija, 2020; Heide et al., 2021). The crisis required organizations to find creative solutions (Ulrich et al., 2021) to ensure the continuity of the previous business model.

Due to the changed framework conditions, changes to existing value chains are increasingly gaining in strategic importance (Thömmes, 2022). The portfolio activities are increasingly supported by the use of information and communication technologies and are increasingly discussed in science (Brunetti et al., 2020; Kucia et al., 2021). Social media is one of the SMACIT technologies (Social, Mobile, Analytics, Cloud and IoT) and makes an important contribution to digital transformation (Aloini et al., 2022; Martini et al., 2021).

The term "platform economy" has populated science and practice since the early 2000s. Platforms serve as a strategic source of information (Brunetti et al., 2020; Konhäusner et al., 2021; Kröger & Marx, 2020). In the age of global, digital connectivity, innovation must be a mainstay of organizational competitiveness. Digital technologies and infrastructures have significantly changed the innovation processes in companies and the collaborative approach (Aloini et al., 2022; Chierici et al., 2021; Kucia et al., 2021; Müller, 2019).

The quality of the customer journey has become a crucial factor in the modern business world. The idea of delighting customers through service excellence is one of the basics in service research and practice (Jaakkola & Terho, 2021). In general, existing marketing literature defines the "customer journey" as a series of touchpoints that customers meet and interact with during their buying process (Boßow-Thies et al., 2020; Thömmes, 2022).

Business models implement organizational strategies (Aloini et al., 2022) and the integration of customers into organizational (portfolio) activities is becoming increasingly strategic (Brunetti et al., 2020; Karlsson, 2022). For traditional companies, scientific concepts and tried and tested applications for business models are still not fully available (Müller, 2019; Thömmes, 2022), despite the many research activities (Aloini et al., 2022). Companies invest in new technologies and change their business model (Brunetti et al., 2020).

2.1 Research context

The importance of innovative health services will continue to increase as a result of megatrends, changing framework conditions and demographics (Kreidenweis, 2018; Müller, 2019). In order to achieve this level of performance, all actors must cooperate across sectors. The sustainable use of resources and the use of business tools for company management are gaining in strategic importance. A networked, sustainable stakeholder orientation with new actors and market participants will emerge and gain momentum (Brunetti et al., 2020; Heide et al., 2021; Tampio et al., 2022).

Organizations in the health and social economy must be adaptable and able to combine external and internal factors in an innovative way (Ludwig et al., 2016) in order to be able to implement holistic care concepts. Companies are complex systems that interact with their environment. Due to the complexity and dynamics of the environment, as in post-corona times, agility and flexibility are expected. Nevertheless, the modeling of sustainable strategies in social economy organizations plays a rather subordinate role (Kreidenweis, 2018; Thömmes, 2022). The changing framework conditions of the (global) market are creating new opportunities to establish innovative business models using BMC (according to Osterwalder and Pigneur) (Müller, 2019). In order to be successful in the long term, the use of synergy effects for systematic market cultivation must be focused (Schmitz, 2007). Thinking in terms of competitive advantages is becoming an iterative strategy process for companies (Heide et al., 2021; Kucia et al., 2021; Straub & Sperling, 2016).

The economy and the differentiated communication are an essential basis for the design of the value-added processes in the health and social economy. The management of scarce goods and ensuring organizational competitiveness will become even more important in the future (Kreidenweis, 2018; Kucia et al., 2021). This requires tailor-made, holistic

management and marketing concepts (Heide et al., 2021; Straub & Sperling, 2016) in order to make social change processes stakeholder-oriented (Brunetti et al, 2020; Kreidenweis, 2018).

3 Methods

As part of a project, the author selected all clients (customers) from an IT point of view who had initial contact with the socio-economic organization in the greater Ulm area, Germany, in the defined period (t_0) 10/2022 to 12/2022. The survey was repeated after 6 months in the period (t_1) 06/2023 to 08/2023.

Customer satisfaction and loyalty were determined using two ad-hoc random samples n = 122 (t0) and n = 109 (t1). For this purpose, anonymous, standardized interviews without freedom of variation were organized using survey cards. The questionnaire includes 12 items to measure customer satisfaction (using the construct *"Customer Satisfaction Score"* – CSAT) and 1 item to measure customer loyalty (using the construct *"Net Promoter Score"* – NPS).

Figure 1. Visualization of the CSAT construct

Source: own illustration
Figure 2. Visualization of the NPS construct

Source: own illustration

After a successful pretest, the participants were able to map their attitude to the categories of personnel (P), administration (A) and service (H) on the 5-level Likert scale as part of the classic customer survey. According to the socio-demographic information, the so-called customer loyalty question **"How high is the probability that you would recommend the service?"** placed. This key question is to be answered by the participants on a scale of 0 to 10, with 0 being very unlikely and 10 being very likely (Staudacher, 2021).

The arithmetic mean and the standard deviation, which belong to the bundle of methods of descriptive statistics, served for the interpretation. The processed data was evaluated using MS Excel and SPSS.

4 Results

High response rates are of qualitative, statistical importance for the project success (Staudacher, 2021). The calculated response rates t_0 = 8.75% and t_1 = 7.45% in the B2C area show that the results are below the typical response rate of 10 to 20% for B2C surveys and

thus limit the representativeness of the sample (Theobald, 2017). Despite the reminder, the response rates could not be increased significantly. Furthermore, the internal consistency calculation of the measuring instrument was carried out and rated as acceptable: > 0.700 (Streiner, 2003). Table 1 shows the results of the questionnaire categories (P, A and H). Cronbach's alpha is an indicator of the reliability of a construct represented by items.

Table 1. Reliability statistics for t_0 and t_1

	Cronbach's alpha		
	P	**A**	**H**
t_0	0.753	0.845	0.865
t_1	0.728	0.838	0.852
Count of items	3	3	4

Source: own illustration

Figure 2 below visualizes very clearly that in the social economy the clients (customers) are generally very satisfied with the service provided, which mean shows. The different criteria for determining customer satisfaction could be evaluated using Likert scaling in five grades from not at all ($= 1$) to completely ($= 5$).

The CSAT calculation is carried out for the respective construct according to the scheme: positive responses (Perfect! & Gut) ÷ total number of responses (Staudacher, 2021).
Figure 2. Results of the customer survey

Source: own illustration

The measurement of customer loyalty was operationalized with the construct NPS and calculated as follows: % Promoters – % Detractors (Staudacher, 2021). The result of the calculation of the NPS value ($t_0 = 54$ and $t_1 = 62$) is shown in Figure 3 below.
Figure 3. Visualization of the NPS results

Source: own illustration

Standardized interpretations and comparative values from other sectors are used to classify the results. Table 2 below helps to classify and interpret the determined value. From the data at both points in time (t_0 and t_1) it can be seen that the socio-economic organization acts in the market in a very customer-focused manner. From a statistical point of view, a positive NPS value should be aimed for – i.e. have more promoters than detractors. The higher the value > 0, the more customer-focused the organization acts. A value > 30 is remarkable. 50 is excellent and > 70 is exceptional in many industries and business sectors.

Table 2. Help for the interpretation of the NPS value

NPS value	Interpretation of the NPS value
> 70	Exceptionally high and very rare in many industries and business sectors.
$50 – 70$	An excellent NPS value, which means the organization is very customer-focused.
$30 – 50$	A remarkably good NPS score.
$0 – 49$	A positive NPS value with further potential for improvement for the company.
< 0 (negative)	There are more detractors than promoters here, which means the organization must initiate improvement measures.

Source: own illustration

An excellent NPS value can be a bad score in another industry. Benchmarking helps to understand the calculated NPS value and to optimize stakeholder orientation (Staudacher, 2021). Various websites and online platforms provide industry-specific comparative values. In addition, the geographic location and socio-demographic characteristics of the interviewees must be considered.

5 Discussions

Portfolio management occupies many companies (Aloini et al., 2022; Tampio et al., 2022; Thömmes, 2022), because customer centricity has steadily gained strategic importance in

recent years (Karlsson, 2022; Kucia et al., 2021; Staudacher, 2021). Profit and customer added value move into focus and change the established business model of organizations. New technologies, increasing customer requirements and changing framework conditions offer many opportunities in the context of digital transformation. Growth and increase in value must be understood as a conglomerate of organizational measures. The communication behavior of the stakeholders has also changed fundamentally as a result of IT. Organizations speak of the loss of information sovereignty. A paradigm shift in communication is emerging (Kröger & Marx, 2020). Megatrends such as digitization, connectivity, sustainability and changing values are key drivers for central changes in the world of work (Boßow-Thies et al., 2020; Karlsson, 2022; Kreidenweis, 2018; Kröger & Marx, 2020). These new circumstances are forcing socio-economic organizations to massively rethink and act innovatively.

Customer surveys are considered an important tool in the world of marketing and promote active stakeholder dialogue (Karlsson, 2022; Staudacher, 2021; Theobald, 2017). Several methods for generating valuable customer insights are populating science and practice (Brunetti et al., 2020; Jaakkola & Terho, 2021; Karlsson, 2022).

6 Conclusions

Social economy organizations are facing a huge change and need to rethink their current strategy and business model. The increasing relevance of business model strategies has been repeatedly emphasized in practice and science in recent years, especially against the background of increasing global competition and increasing customer requirements (Kucia et al., 2021). So-called standard strategies (according to Ansoff or Porter, among others) can be used to help with general structuring.

If you want to look into the future, you should evaluate the framework conditions of the organization. In the context of business model innovations, the parameters mindset, technology, economy and demographics play an important role.

Digitization is constantly changing all sectors and requires a modification of previous business models (Boßow-Thies et al., 2020; Brunetti et al., 2020). The stakeholders of a (social economy) organization are not only a target group, but also become organizational ambassadors and make a strategic contribution to the significant and innovative competitive advantage (Kröger & Marx, 2020; Kucia et al., 2021; Tampio et al., 2022). Agility and flexibility play an essential role in modeling stakeholder-oriented processes. Operational value creation and business models are becoming "digital" – tools and holistic IT systems are becoming a strategic competitive factor (Thömmes, 2022).

Finally, the author proposes to test empirically whether Eastern EU countries provide comparable results, in order to check whether the results can be generalized, especially in the context of the social economy. Furthermore, the results from the internal and external surveys could be used as a so-called dialogue tool for sustainable organizational and portfolio development. Another construct that could be used is the Customer Experience Score (CES), which evaluates the customer's interaction with the company (Staudacher, 2022). The CES is often used in the eCommerce area.

Impacts of globalization on the behaviour of young consumers

Aleš Hes[1,*]

[1]University of Finance and Administration in Prague, Estonska 500, CZ 101 00, Prague 10, Czech Republic

Abstract

Research background: Globalization has developed the interconnection of national economies and has become an effective platform in the development of international trade. At the current time, when the world is recovering from the effects of the COVID 19 pandemic and the current political-military crisis between Russia and Ukraine, it can be expected that changes in the behaviour of young consumers will occur in Europe. The increase in consumer goods inflation and high energy prices will be a clear cause of this.

Purpose of the article: The article tries to find realistic ways to minimize the negative effects of the current global crisis of international trade on the needs and interests of young consumers based on a complex analytical reasoning.

Methods: The main methods used are a structured analysis of real facts regarding the impact of globalization on national economic interests and on the behaviour of consumers from generation Z, as well as a cognitive description of the facts, as well as synthesis methods, logical and deductive procedures in order to verify the proposed paths leading to the minimization of the impact of globalization on behaviour of young consumers.

Findings & Value added: The article will present the consequences of the current global crises on the national economy of the Czech Republic and their influence on the change in the behaviour of young consumers of Generation Z, and will provide general recommendations for mitigating the negative effects of the current global trade crisis on the surveyed consumers.

Keywords: *globalization*; *corporate enterprises; consumer behaviour; crisis; incorporation;*

1 Introduction

Globalization has created the conditions for the rapid development of a consumerist postmodern society that increases its demands for its comfortable lifestyle. Large multinational corporations have emerged, which today also strongly influence political decisions in individual states. The commercial and economic structure was linked in terms of ownership and economy, and thanks to the development of information technology, all links were linked in a strong network with significant interdependence. This process of global interconnection represents an economic driving force for the development of society as a whole in all cultures of the world and is a new trend in international trade. Of course, all this is reflected in changes in consumer behaviour. Although the protests of various civil movements are growing against globalization, thanks to the unevenness of, for example, subsidy titles for some products that bring price disparity in different markets (Stiglitz, 2006), global trade is currently a phenomenon that fundamentally affects the behaviour of consumers, especially the young generation. In a certain way, the young generation behaves differently as a consumer than the previous generation /generations Y and X/. The comfortable lifestyle provided by their parents and especially the global society allows them not to worry about the possibility of certain crises with negative impacts on their standard of living. Generation Z is strongly influenced by social networks, they live on the border between online and offline, from which they draw all possible information, including what to buy and how to behave. They don't just buy what they need to survive, but what they enjoy and what their favourite influencer recommends. Generation Z is surrounded by interactive media and this is significantly reflected in their purchasing behaviour. It is therefore necessary to show this young generation of consumers the possible risks of purchasing decisions associated with the possibility of crises (COVID 19, the war environment in Ukraine) and to create alternative solution paths for them.

2 Material and methodology

The main methods that were used in the processing of the mentioned issue were structured analysis and in particular the description of facts and their arrangement according to general laws, as well as synthesis methods, logical and deductive procedures with the aim of correctly formulating, on the one hand, the sources of possible global crises affecting the purchasing decisions of the young generation Z, on the other hand theoretical starting points leading to the construction of a real solution. The topic is organized according to the logic of facts and through deduction from analyses of scientific texts and real global phenomena, to formulate, identify and characterize real measures to minimize the impact of crises on the young generation of consumers.

3 Results and discussion

Globalization is currently a very topical topic for all economically and property-related countries. The entire system was built on the integration of management and organization of production, including services at an international level. Globalization processes rose above internationalization, where the main characteristic was the promotion of international trade in goods within national economies. However, with the emergence of multinational corporations, the borders between individual states disappeared and they began to take advantage of production factors in local parts of the world in order to minimize production costs and increase their profits. Dicken (1992) already formulated globalization as a functionally integrated system of geographically dispersed economic activities. Despite the

considerable benefits of globalization processes, which have brought about a disproportionately consumerist way of life for the entire society, there is currently an increasing number of crises (financial, health, pandemic, political, energy). The young generation in particular, and generation Z in particular, have become accustomed to a comfortable way of life that does not count on any possible crisis wave. These began to manifest themselves most with the pandemic crisis caused by COVID'19, which became the cause of the global economic recession (Adžić S., Al-Mansour, 2021). Even Hazdra (2013) drew attention to the danger of global phenomena for the tertiary sphere of services. Cross-border crisis was highlighted by Backman (2020) as a result of examining different crisis management within the framework of central crisis resolution. Hall (2010) in turn examined hypermobility in tourism, which is a consequence of increased crisis events in international tourism. The entire process of political crises has been covered by studies that serve to understand the complexity of integration caused by the crisis (Hooghe, Marks, 2019, Moravcsik, 2018, Niemann, Ioannou, 2015, Schimmelfennig, 2018, Saurugger, 2016).

Currently, there is a close interdependence of production and business processes, which leads to the consequences of risky interdependencies, which in the local environment can cause a certain product shortage in the event of a social conflict or crisis. The so-called reverse globalization has a significant non-linear negative effect on the economy and export trade. It has significant inhibition of export of secondary industry followed by tertiary industry. This is evidenced by Chinese exports of industries with high product complexity /for example, metal products, pharmaceuticals, electrical and optical products/, which are significantly affected by reverse globalization than products in the construction industry, land transport or in the export of water transport (Wang, 2022).

The development of companies is also affected by parallel manifestations of the dual economy, which is particularly evident in developing countries. Even though globalization harmonizes and standardizes everything, there are phenomena that can be the cause of crisis waves and subsequent recession and economic crisis. The international market and the international financial system have become the most critical part of national market systems. These are mainly manifestations associated with a dynamic redistribution of labour forces with an erroneous redistribution of resources. This can lead to internal markets being affected by the lack of functional institutions and the growth of social disparities (Popovic, Radevic, 2022).

It is the problem of social disparities both in the internal markets of countries and between countries that causes social insecurity in certain sectors of the labour market. For the young Generation Z, the future of work represents one of the most significant challenges facing most researchers and managers worldwide. The rapidly developing era of digital globalization and smart digitization, trends in robotization and artificial intelligence have completely changed the labour market. Therefore, through accelerated information technologies, most global (multinational) corporations are adopting solutions in the form of total systemic digitization, which is able to replace declining jobs or places where people are not interested in them or there is a very limited number of qualified workers who would fill the given job processes could perform. This is mainly the introduction of robotization, total automation, drones, all controlled by intelligent control processes (Rashid, 2022).

Thus, according to current developments and technological advances, the impact of artificial intelligence on the future of work will be significant. For Generation Z, this means focusing on those jobs that cannot be easily replaced by artificial intelligence. Already, the current increase in automation and computerization poses the risk that many craft jobs will be lost to automation in the future. Behind these development trends, it is necessary to see the efforts of global companies to increase productivity, reduce costs due to innovation and speed up changes. The current trend in the labour market is changing as a result of three global simultaneous significant shifts:

1. Demographic shift, including population aging, especially in Europe
2. The economic shift of digital globalization that creates digital platforms and strengthens the economy of business across borders.
3. Technological shift driven by the Internet including artificial intelligence, big data and cloud computing.

It is clear that current technology will affect jobs worldwide, however some industries could be affected more than others (Eichengreen, 2019).

The digitization of society and the introduction of artificial intelligence into production and work processes will clearly affect Generation Z not only in their employment on the labour market, but also as consumers. The purchasing behaviour of this young generation will adapt to the development of digitization of business processes. Generation Z belongs to the generation that is surrounded by interactive media from an early age and grows up in a Web 2.0 environment. and which is strongly influenced by its surroundings. Their behaviour can be called "methodological collectivism", which is characterized by a strong influence of marketing, communication manipulation skills and the development of consumerism. Mirzoeff (2018) states that generation Z lives in both virtual and physical reality, has a simple approach to world events, sees world problems, wants to find solutions. For this generation Z, the importance and content of information and quality communication will be decisive when making a purchase decision. They will remove uncertainty and the effects of crises. Marketers know this and are working intensively on the wide availability of information sources, which are key for Generation Z to make the right decision. This reduces the risk of a drop in interest in a certain offer, and can also trigger quick and correct reactions in the framework of crisis management for business companies. All new advances, innovations in management and manufacturing, including additive technologies, rely heavily on information (Hannibal, 2020).

The global influence on the young generation is undeniable. In the case of their purchasing decisions, information will be of key importance in shaping their desires, attitudes and values. The retail form will have to gradually change to a digital platform working with information, communication networks and a perfect logistics infrastructure. From a retail position, employees will be educated in new forms and tools of digital communication in order to fully meet the demands of Generation Z. The reason for these changes is that it is the young Z generation whose lifestyle is social networks and their world is strongly influenced by the digital environment. This generation is not so interested in politics, they don't want any conflicts because they realize that it would take away their comfortable life and carefree lifestyle. Thus, one cannot completely agree with Prensky (2001), who refers to this generation Z as digital natives, because they are not led to use technology equally and know how to use the necessary information from it. Practice currently shows /using the method of observing the behaviour of generation Z in their natural environment in 2021/ that this generation of course has the most fun in the digital environment, but they can search for information when they need it and process it according to their mental equipment. Gui et al (2017) considers it as a new digital skill.

The behaviour of the young generation Z is therefore completely under the influence of digital technologies and information. Global network processes bring them all the available information they need to make their own decisions. However, there can be one big problem here. The disproportionate dependence of the young Generation Z on global networked communication processes can make them vulnerable if they malfunction. They may experience psychological problems in the form of frustration, depression, insomnia, anxiety. The starting point and preventive solution to these unwanted consequences of a global network outage is the creation of an educational space in digital form, which would teach Generation Z to understand the parallels of solving their wishes and desires. The goal of this educational process is to teach this generation Z to use information technology more

pragmatically for their growth and self-realization, and to explain to them the dangers of relying on social networks and media noise.

3.1 Predictive buying behaviour of Generation Z

From a global perspective, the studied young generation Z represents a growing and significant force that will significantly influence the dynamics of the global economy. By 2031, their income is expected to increase fivefold. Their number is over two billion worldwide, with nine out of ten living in emerging markets, e.g. in India it is one fifth, in the USA Generation Z represents 40% of all American consumers. When it comes to purchasing decisions, Generation Z has its favourite brands, but only 36% express a strong sense of loyalty to any company's brand. If a marketer's target audience can be identified from Gen Z analytics, here are important factors a marketer must consider:

1. They love sustainable business practices.
2. They monitor affordability.
3. They tend to brand products, are influenced by their peers and influencers.
4. They do not reject green initiatives, they support recycling.
5. They buy from a variety of companies, it is very difficult to cultivate them as loyal and loyal consumers.
6. From communication tools, they will focus on advertising and interesting events, however, this is not key for them when deciding to buy a product.
7. They want to communicate in a digital environment, they expect an immediate response, they are impatient when problems or collisions occur in the product range.
8. They explicitly draw information from the Internet (Wallace, 2022).

Digital communication is key to the behaviour of Generation Z. If the use of individual global means of communication can be evaluated, it can be based on the research of the Polish authors Król and Zdonek. Among the most popular social media services among Generation Z is the tech giant Google. The most frequently used tools are Messenger and Facebook, which the young Z generation uses several times a day, as well as YouTube and Instagram, Snapchat and Spotify. As other social media services and online communication tools, Generation Z uses: Steam, Vinted, Aliexpress, Teams, Zoom, Discord, Tumblr, Reddit, Tiktok, Netflix, Viber, Tinder, Pinterest, Goldenline and Wattpad (Król and Zdonek, 2021).

It can be assumed that the young Z generation will also use these communication tools when choosing a certain product or service. For the business world, this means a signal that without digital information and a networked media environment, it will not make a significant impact on this generation.

The purchasing behaviour of Generation Z can also be characterized using the example of purchasing a specific product. This is proven by the results of research by Brand, Rausch and Brandel (2022), who state on the specific example of buying a jacket that for Generation Z the most important factors are the price of the product (25.95 %), the design (20.79 %) and where the product was made (15.96 %), followed by eco-labels (10.66 %), social labels (10.20 %), used materials (9.54 %) and jacket functionality (6.90 %). Generation Z prefers recycled materials over biological and synthetic ones. They prefer products made in Europe and Germany over products made in Asia. Since the research was conducted in Germany, it is clear that the familiar German patriotism was manifested here.

The global environment is a crucial platform for Generation Z to influence their behaviour. Generation Z belongs to mainstream culture because it has the ability to communicate with the whole world. He does not shop for his own needs, but for pleasure and happiness. This young generation is heavily influenced by media networks and influencers, and although they want to behave diversely and differently from others, their behaviour tends

to show a certain homogeneity and uniformity. Prudký (2009) described her model of behaviour as methodological collectivism, which means that she is an individual who pursues her own benefit, but her actions are influenced by the opinions and values of those around her.

3.2 Current global impacts on Czech consumers and generation Z

Currently, crises are a manifestation of turbulent phenomena in social and economic life and manifest themselves in the form of crisis waves. Crisis waves arise unexpectedly, however, they can be predicted based on changes in society's behaviour. Crisis waves arise in all areas of the national economy and in sectors. Recently, the pandemic crisis caused by COVID 19 has resulted in a recession in economic development and in some sectors, especially in the tertiary service sector, it has caused a real crisis that has threatened the existence of many business entities. Individual countries dealt with the pandemic in different ways, depending on the existence and functionality of the system of early warning before crisis waves and alternative solutions in threatened sectors. The Czech company emerged from this crisis situation on the verge of saving the most threatened business activities, especially in gastronomy and tourism. However, the effects of this crisis wave are still visible in many Czech business entities. So society was able to cope with this worldwide global pandemic crisis and a new crisis wave occurred in the form of a war conflict between two European countries. Political tensions can be observed all over the world, however, Europe has behaved for over seventy years as a non-conflict association of mutually prosperous economies, and global economic interconnectedness guaranteed stability not only in the economic field, but also in the political field. Every player in the international markets was aware of strong trade dependencies, and therefore no one expected that a crisis wave of war conflict would occur, which would bring significant difficulties in the form of availability and limited energy resources, on which European states are heavily dependent.

Czech consumers are most concerned about rising prices, the military conflict in Ukraine, and poverty and social inequality. Far more than other European consumers, Czech consumers worry about their standard of living, which is threatened by high inflation, poverty and the involvement of the Czech Republic in a military conflict. On the contrary, problems with corruption, crime, violence and unemployment receded. Czech consumers, and especially generation Z, are most worried about rising food, energy and transport prices and limited travel, and their confidence in the Czech economy is decreasing. Only 14% of consumers consider the current economy to be strong and only 8% of consumers believe that the Czech economy will be stronger by the end of 2022. Only ¼ of consumers perceive their financial situation as good, only 15% of consumers believe in improving their financial situation by the end of 2022. In the first place, Czech consumers perceive an increase in food and energy, slightly less perceive changes in prices in catering, accommodation and transport (www.ipsos.com).

Generation Z is most concerned about their standard comfort, which they have chosen as a lifestyle. He cannot accept the impending shortage of products and limited services. Generation Z is very sensitive to crisis waves, however, they cannot fully imagine that the crisis will really affect them fully. They always believe in certain procedures that will solve the crisis. However, it is not the generation that could solve the situation on its own. The only way out is how to get Generation Z to actively engage in the economic world with the help of educational programs and further unity of opinion leading to the removal of all indications leading to the emergence of crisis waves and crises themselves, especially in the digital environment.

4 Conclusions

In the case of preparing Generation Z for possible handling of crisis situations that disrupt their standard lifestyle, it is necessary to lead them to pragmatic use of information and communication technologies, divert them from low-quality social networks in a fun way and increase their digital skills with the help of educational game projects. In the area of consumer behaviour, it is necessary to teach them, with the help of sophisticated education in families and in public institutions, to pragmatically and critically evaluate all possible information that could negatively affect Generation Z.

From a global retail perspective, it is clear that Generation Z will be most interested in information in a digital environment. Generation Z requires information that they can evaluate themselves and make a purchase based on it. The young generation Z demands affordability and likes brands of goods, although it is very difficult to turn them into loyal and loyal customers. They tend to brand products especially through global advertising and are heavily influenced by their peers and influencers. Generation Z likes diversity, they do not reject green and environmental projects, however, they identify themselves as a homogeneous and uniform society by their behavior. And this can be used very well in retail strategies.

Level up: Metaverse as a new marketing channel for medium-sized companies in Germany

Neele Hiemesch-Hartmann[1,*]

[1] Berlin Institute of Finance, Innovation and Digitalization, Badensche Straße 52, 10825 Berlin, Germany

Abstract

Research background: The expectations for the new Metaverse have overturned in the recent past, especially on the part of companies. It almost seems like a paradigm shift has begun in how companies and consumers communicate. The first companies are already utilizing the Metaverse. It was primarily international corporations that made an appearance. They implement the first pilot projects and gather insights into the possible uses of the Metaverse. However, the German economy is characterized by medium-sized companies in particular. They represent the majority in terms of their number and turnover in Germany. This fact makes it evident that the previous perspective on the Metaverse should be completed. This supplement is a medium-sized view, often associated with less personnel and budget resources than international corporations. These arguments create new opportunities in the Metaverse to do marketing with limited resources. Medium-sized companies can participate differently in the new marketing channel Metaverse than large corporations**.**
Purpose of the article: The perception and possible uses of the new marketing channel Metaverse are examined using secondary market data. These are first researched, checked, and analysed. Subsequently, German medium-sized companies are examined using key company figures. It should uncover possible industry focal points. The previous perception is then compared with the demands of medium-sized companies in Germany. It should uncover possible fields of action, and recommendations for action for medium-sized companies in the context of Metaverse should be derived.
Methods: A systematic analysis of information and datasets in Germany's medium-sized companies and the use-cases of Metaverse.
Findings & Value added: Creation of an information base regarding the new marketing channel Metaverse and the application areas.

Keywords: *Metaverse; medium-sized companies; marketing; communication*

1 Introduction

The Metaverse is a virtual world in which time and place are dissociated. Avatars and virtual reality glasses use this virtual world. In October 2021, Mark Zuckerberg announced that the Metaverse would become the key topic of the social media company. With this announcement, the Metaverse experienced an enormous media discussion. In this discussion, skeptics devalue & decipher the Metaverse, and optimists upgrade the topic. For example, skeptics argue that the Metaverse is seen as a new edition of the well-known Second Life platform and is underdeveloped. Optimistic companies have already bought virtual reality glasses on a large scale and see an announcement of a paradigm shift in marketing. Goldman Sachs has already estimated several trillion US dollars sales forecasts for the Metaverse per year. It is noticeable that large companies, have initiated the first pilot projects in the metaverse (Hennig-Thurau and Ognibeni, 2022). In Germany, however, most companies are small and medium-sized enterprises (SMEs). These SMEs have specific challenges, unlike large enterprises. For example, SMEs generally lack staff and budget compared to large enterprises. In addition, German SMEs face enormous challenges in digitization. However, the marketing strategy of SMEs also differs from large companies. For example, many SMEs operate in a B2B relationship and are represented along the entire value chain (IfM Bonn, 2022a).

The Metaverse approach has extensive disruptive potential for companies and their marketing. To participate in this potential, SMEs must engage with this trend. If they miss this opportunity, SMEs will be left behind in the Metaverse marketing arena. This paper will first explain the Metaverse construct and present the implications for marketing. Subsequently, the German SME is outlined, and the specific challenges are derived. For this purpose, adaptation possibilities of the Metaverse for SMEs are highlighted and discussed.

2 Methods

This paper consists of a literature review. So far, the majority of the Metaverse exists as a concept. Therefore, no robust data basis exists. Instead, SMEs' challenges are contrasted with the theoretical possibilities of the Metaverse. To this end, the possibilities of Metaverse as a marketing tool are explored below.

2.1 Theoretical framework of the research

2.1.1 Definition Metaverse

The term Metaverse combines "meta" and "universe." "Meta" here refers to a transcendent state. In the context of the Metaverse, the term "universe" is understood as a digital simulation that has a connection to the physical environment (Stephenson, 1992). The term Metaverse is not uniformly defined. Thus, different approaches and concepts exist to describe the Metaverse as a digital reflection of reality or spatial Internet. In the Metaverse concept, users can create a digital avatar and move around in digitally simulated worlds using virtual reality glasses (Njoku et al., 2022). A central role in the Metaverse concept is played by the company Meta (formerly Facebook). Meta launched the game "Horizon Worlds" in 2021, but so far, it is only available in America and Canada. The company Meta sees itself as an enabler to make the concept of Metaverse accessible worldwide (ArkInvestment, 2021). According to Hennig-Thurau and Ognibeni (2022), the Metaverse is succinctly defined in terms of three properties:

1. Virtual worlds: The Metaverse provides the third dimension. Users move into a virtual world instead of surfing from one website to the next. The Metaverse is permanently available and usually requires virtual reality glasses.
2. Avatars as identity: Users create avatars with which they move through the Metaverse. Unlike Instagram or Zoom, the communication focus is not on the natural person but on the avatar.
3. Social network: Unlike the Internet, the Metaverse is a social institution. Thus, the benefit comes from the presence of other users. The social factor arises from user interaction and joint activities such as a joint virtual concert visit.

In this work's context, the Metaverse concept is understood as a digitally simulated parallel world (Njoku et al., 2022). It is essential to emphasize that this is a conceptual approach that has only been implemented in part in practice to date.

2.2.2 Implications of the Metaverse for Marketing

The Metaverse concept shows multiple implications for marketing. By dissolving temporal and spatial factors, a variety of re-alignments emerge. At the same time, technological possibilities offer new opportunities for communication with consumers. This paper discusses two relevant approaches: omnichannel and consumer experience. These two approaches have a disruptive character and impressively demonstrate the implications for marketing. However, it remains to be said that there can be many more implications, which can affect marketing with different strengths.

Omnichannel
Linking analog and digital sales channels in the omnichannel concept is common practice for many companies. Ideally, analog, and digital sales channels merge, and consumers jump between these channels. This combination also leads to a merging of analog and digital marketing activities (Hilken et al., 2022). The Metaverse concept reinforces the trend of omnichannel concepts many times over. For example, consumers can check out products via virtual reality glasses during the purchasing process. This new approach creates new opportunities to make products tangible along a purchase decision process (Nevelsteen, 2018). Consumers have different information needs along the phases of the purchasing process. By using the Metaverse concept, reality-enhanced consumer experiences are conveyed (Joy et al, 2022). In addition, new purchase incentives can be explicitly created by marketing. This results in a wider range of cross-selling and up-selling opportunities for marketing (de Ruyter et al., 2020). The first online stores with the Metaverse approach already exist. Here, digital users can buy products such as clothing & home furnishings (Frings, 2022).

Communication channel for Consumer Experience
The critical difference between the Metaverse and social networks is that users can experience things together. Things experienced together can generate feelings in consumers (Hennig-Thurau and Ognibeni, 2022). The Metaverse enables the possibility for consumer experiences that lead to increased consumer engagement. Reality-enhancing technology creates memorable digital experiences. Consumers try products and visit events around a product or brand in a digital environment. This approach enriches communication between companies and consumers (Ibáñez-Sánchez et al., 2022). The first pilot projects are emerging in the form of virtual showrooms. These animations of products, meeting rooms and events are presented to customers (Frings, 2022). In the Metaverse approach, companies and customers enter the dialog. It is currently still unclear if this type of consumer experience has a sustainable character. In the scientific community, for example, the view is that this

consumer experience has a short-term aspect. The novel character attracts the interest of customers. Only time will tell whether this interest is sustainable (Ibáñez-Sánchez et al., 2022).

It becomes evident that many implications of the Metaverse concept still result in theoretical considerations. This circumstance is due to its novelty. The novelty is clearly shown by the fact that so far, there have only been initial pilot projects by large companies with a Metaverse concept (Hudson-Smith and Batty, 2022). Nevertheless, the disruptive character should be underlined at this point. For example, the digital dissolution of space, time, place, and objectivity has an enormously disruptive influence (if not a reordering) on marketing (Hsieh and Vergne, 2022). Companies must come to terms with this new approach. So far, market observations show that only large companies are taking the first steps in the Metaverse.

2.2 Practical framework of the research

2.2.1 Definition of small and medium-sized enterprises in Germany

SMEs can be defined using qualitative and quantitative criteria. On the one hand, the term "small and medium-sized" in Germany is defined based on qualitative criteria. Ownership and management must form a unit in medium-sized companies. The owner of a medium-sized company is, therefore, also the manager. Another qualitative criterion is that the entrepreneur exercises a significant personal influence on the company's activities. He also bears the risk for his entrepreneurial decisions. The company serves the entrepreneur as a means of securing his livelihood (IfM Bonn, 2022a).

The European Commission defines SMEs based on quantitative criteria. These criteria include the number of employees, the annual turnover, and the balance sheet total per year. There are gradations between micro-enterprises, small enterprises, and medium-sized enterprises. Small companies have up to 9 employees, up to 2 million euros in annual sales, and up to 2 million euros in total assets. Small companies are companies with up to 49 employees and up to 10 million euros in annual sales and 10 million euros in total assets per year. The last gradation of the middle class is medium-sized companies. These companies have 249 employees and up to 50 million euros in annual sales or 43 million euros in total assets per year. Companies with more than 249 employees based on the number of employees, more than 50 million annual sales, and more than 43 million euros in total assets are not classified as medium-sized and are considered large companies (European Commission, 2022).

2.2.2 Economic indicators of small and medium-sized industry in Germany

According to the German Business Register, from 2020, 3,374,583 companies were registered in Germany. The proportion of SMEs in Germany is 99.3% of all registered companies. Thus, only 0.7% of German companies are large companies. The cumulative turnover of all registered companies in 2020 is 6,879.85 billion euros. The turnover share of SMEs is only 33.7%. Thus, one-third of the turnover is accounted for by SMEs, while large companies, which nominally make up the clear minority (0.7%), are responsible for around two-thirds (66.3%) of the turnover generated. It also shows that 16.8% of export sales are attributable to SMEs. More than half (54.4%) of employees in Germany (a total of 34.93 million in 2020) work in SMEs. Apprentices, often employed in companies for the first time, are primarily trained in SMEs. 70.6% of trainees in Germany worked in SMEs in 2020 (IfM Bonn, 2022b).

In 2020, 93.93 billion euros were invested in research and development. Only 8.2% of these investments are due to SMEs. This fact underlines that a minority of large companies (0.7%) account for the majority (91.8%) of research and development investments (IfM Bonn, 2022b). The figures clearly highlight that SMEs are an essential pillar of the economy in Germany. These make valuable contributions to the economy itself and the labor market. However, most sales, research, and development budgets lie with large companies. Depending on the different industries, however, a complex picture can emerge. SMEs are often absolute industry leaders in niche markets. Table 1 shows the balance of power in the German economy between SMEs and large companies in general.

Table 1. Germany: SMEs versus large companies, 2020.

Indicators	Total	SMEs	LC*
Number of companies	3,374,583	99.3%	0.7%
Turnover of the companies**	6,879.85	33.7%	66.3%
Dependent employees in***	34.93	54.4%	45.6%
Trainees in companies***	1.54	70.6%	29.4%
Export sales**	1.128,45	16.8%	83.2%
Corporate R&D Expenditure 2020**	93.93	8.2%	91.8%

2.2.3 Challenges for small and medium-sized industry in Germany

Like large companies, SMEs are shaped by today's volatile economic conditions. Markets cannot be clearly defined, customer needs vary, and product portfolios are less stable. At the same time, there is not only national competitive pressure but rather international competitive pressure. The shortage of skilled workers and the topic of sustainability pose further challenges. However, some of these challenges also apply to large companies (Ludwig et al., 2016). SMEs often have the problem of budget & staff constraint than large companies. This fact means that they often have fewer options within the company. In addition, failures at SMEs are not supported by a broad product portfolio. SMEs face a greater risk when making decisions than large companies (Mueller and Spitz-Oener, 2006). However, a unique challenge for medium-sized companies is digitalization. These digital challenges include the digital design and empowerment of SMEs. Digital design means developing a resilient entrepreneurial and digital strategy. This digital way is the only option to adapt and adapt quickly to volatile market conditions. Recognizing and using the chances and possibilities of big data is essential. Ideally, big data will become a relevant business model for SMEs. Another challenge is to make value chains, production processes, and technologies more digital. This digital design then offers possibilities for automation and the use of artificial intelligence. At the same time, medium-sized companies must ensure data protection and increase IT security. These challenges can only be achieved through the expansion of digital infrastructure. Ultimately, today's SMEs must consider the effects of digitization. It shows that consumer behavior changes from analog customer wish to digital ones (IfM Bonn, 2020).

By bringing together the theoretical and practical frameworks of the research conducted, it is shown that there are enormous implications for marketing from the Metaverse concept. These concepts are theoretical considerations from first pilot projects of large enterprises. Furthermore, the view into the economic structures of Germany shows that SMEs mainly characterize these. At the same time, the unique challenge of SMEs in Germany is lack of digitization. It is, therefore, understandable that large companies are making the first attempts in the Metaverse. This development puts SMEs at a further disadvantage in the context of

digitization. It is, therefore, necessary to examine what opportunities the Metaverse approach promises for SMEs. The challenges and opportunities for SMEs in the context of the Metaverse are examined below.

3 Results

In Germany, SMEs primarily operate in a B2B relationship. Many companies operate in the intermediate input industry and have companies as customers (IfM Bonn, 2022b). This fact corrects the marketing perspective to a B2B perspective. With this perspective, two options for using the Metaverse as a marketing channel are possible: Companies meet customers, and customers meet customers.

Companies meet customers
Especially companies from the intermediate goods industry and thus also SMEs have extensive industrial goods facilities. These are often distributed at decentralized locations worldwide, and individual manufacturing steps are thus performed at different locations. The manufacturing processes are complex and consist of a mesh of input and output factors (Goto et al., 2020). As a result, the manufacturing process is intricate and challenging to communicate to potential customers (Mallapragada et al., 2022). The Metaverse can be a relevant marketing channel here. Through virtual representations of the manufacturing processes, a "walk-through" manufacturing model exists. These virtual machine systems can be explained down to the smallest detail. The complex interrelationships can be experienced and thus become more comprehensible. In addition, industrial plants can be inspected during ongoing production without having to stop production for inspection. This option would be impossible in the analog world. The virtual representation of decentralized industrial goods plants shows the entire manufacturing process. In the analog world, only one site can be visited, but not several at the same time. This fact saves customers' time & travel costs and is also more sustainable. Hence, it is also a straightforward solution in the B2B customer approach. While a firm purchase intention often accompanies an actual site visit, initial prospects can form a virtual picture of a company and its products or services. The efforts required by the customer are, therefore, significantly less in the Metaverse. It can, therefore, also be assumed that the customer approach is simplified in the Metaverse (Hennig-Thurau and Ognibeni, 2022).

Customers meet customers
Another way for SMEs to use the Metaverse as a marketing channel is to create company and customer events. B2B has a network of relationships between customers and companies. Purchasing processes are much more complex as numerous decision makers are involved. As a rule, not one customer makes the decision, but many players make a shared decision. These sales processes include clarification of technical details and legal obligations such as warranties and guarantees. However, social togetherness is a critical point in the purchasing process (Mallapragada et al., 2022). This social togetherness can be redesigned in the Metaverse. Virtual events can connect customers and enable them to experience the company, products, and services. Joint customer events are designed virtually, and customers get into spontaneous conversations with other customers. They can also share their experiences with the company. This option is made possible by overcoming geographical boundaries. This way, customers can enter a conversation with other customers far away from each other. In the analog world, this would only be possible with enormous effort and is unusual for informal conversations. It is also possible to create events without time limits. Therein lies an attraction to overcome time zones from different parts of the world. This fact is where the Metaverse concept can offer real added value. It saves customers' travel costs

and ensures more sustainable communication. The prerequisite is that a Metaverse event creates an authentic customer experience (Hennig-Thurau and Ognibeni, 2022).

4 Discussion

From today's perspective, it is difficult to assess what disruptive character the Metaverse will assume in the future. The forecasting opinions differ widely here. The attitude in science and practice is that the Metaverse is completely overestimated. Nevertheless, there is also the exact opposite opinion. Some representatives emphasize that companies must invest massively in the Metaverse concept. This situation is a classic case of dissent. Currently, pilot projects of large companies show first successes. Only the future will show whether this will be a sustainable success. From the point of view that the Metaverse will become established, there are several opportunities. It is essential for SMEs not to leave the Metaverse marketing channel to large companies alone.

SMEs are often faced with a lack of budget and human resources. The Metaverse concept could address some of this shortage because the implementation is cost-efficient. In addition, costs such as travel expenses are eliminated. At the same time, the Metaverse offers enormous potential for digitizing business processes simply, cost-effectively, and promptly. SMEs especially have difficulties in the context of digitalization. This paper shows the first examples of how to use the Metaverse meaningfully. SMEs must now get a grip on the topic. To do this, they must get to know the Metaverse and try it out. SMEs then must identify possible applications for themselves. Not all the advantages of Metaverse apply to all companies. Here, SMEs must find their ways and options. These possible options must then be implemented in small steps. The "wait" strategy is not an option until more established marketing concepts are successful in the Metaverse. If SMEs continue to be reluctant to join the Metaverse, leave the marketing channel to the large enterprises. Over time, this will increase the competitors' lead, if not make it uncatchable.

Supporting Young Farmers Within The Common Agricultural Policy

Jana Hinke[1,*], and *Miloš* Nový[1]

[1] University of West Bohemia, Faculty of Economics, Univerzitní 8, 301 00 Pilsen, Czech Republic

Abstract

Research background: The Common Agricultural Policy ("CAP") accounts for the largest share of the EU expenditure. The original rules of CAP are in force until December 2022, then the latest reform will come into effect until 2027. One of the top ten objectives is to support young farmers with at least 3% of the budget.

Purpose of the article: This raises the question of how the CAP direct payment funds were distributed to young farmers under the original rules, or rather how their support will change from 2023. The paper assesses the amount of direct payments to young farmers and describes the supporting arguments by reviewing recent studies from scientific databases.

Methods: The analysis of five-year period (2015-2019) was carried out, focusing primarily on the Czech Republic and Slovakia. The authors also compare the situation with the other countries of the Visegrad Group and the founding members of the EU. The statistical yearbooks of CAP of the European Commission are the data source.

Findings & Value added: The CR and Slovakia do not show the same trend in the support for young farmers from direct payments. The method of calculating direct support is also different. The analysis has not revealed any unifying elements common to the Visegrad Group countries or to the EU founding members. Thus, this finding points to national approaches in determining direct support for young farmers. An increase in direct support to 3% will mean a substantial increase, with the CR and Slovakia experiencing the biggest change.

Keywords: *Common Agricultural Policy; direct payments; young farmers; expenditure; support.*

JEL Classification: *F02, F15, Q18.*

1 Introduction

Agriculture is indisputably one of the most important sectors of the national economy. Although the total agricultural production accounted for 1.8% of gross domestic product in

---

the European Union between 2016 and 2019 (European Parliament, 2022), the amount of expenditure related to agriculture and rural development (Sustainable Growth: Natural Resources) oscillated between 27% and 35% (Ministry of Finance, 2022a).

Agricultural businesses in the European area primarily receive funding through the Third Spending Heading of the Multiannual Financial Framework for the period of 2021-2027, totaling €401 billion, plus €18.94 billion from the Next Generation EU. The Third Heading consists, among others, of the Common Agricultural Policy of €386.6 billion, the Environment and Climate Action Programme (the so-called LIFE for short) of €5.4 billion, the Common Maritime and Fisheries Policy of €6.1 billion, and the Just Transition Fund of €19.3 billion. The Common Agricultural Policy (CAP) is made up of the so-called first and second pillars. The first pillar, which is used to make direct payments to agricultural entities and to support agricultural markets through the European Agricultural Guarantee Fund (EAGF), will manage €291.1 billion (in current prices) between 2021 and 2027. The second pillar is used to finance rural development through the European Agricultural Fund for Rural Development (EAFRD), with the total amount of €95.5 billion. These figures are in current prices (Ministry of Finance, 2022b).

Based on the latest data available from the European Commission (European Commission, 2022a), the EU support to farmers amounted to €58.82 billion in 2019. This support was directed at three areas, namely income support including the income stability for farmers, rewarding environmentally friendly farming, and support to state farms amounting to €41.43 billion, market measures amounting to €2.37 billion, and rural development amounting to €14.18 billion. The EU long-term budget, or the Multiannual Financial Framework (MFF) sets the rules on how the CAP funds are spent. The original CAP rules expired on 31 December 2020. The transitional rules remain in force until the end of 2022. The new rules will come into force on 1 January 2023 and will be in force until 2027.

The new reformed CAP will focus on a greener and fairer CAP, and on improving competitiveness. Ten specific objectives result from the above-mentioned intentions, which relate, inter alia, to ensuring fair and sustainable incomes of farmers, increasing competitiveness in the short as well as long term, increasing farmers' added value in the entire value chain, mitigating climate changes, caring for the environment, protecting the landscape, generational changes, rural development, food quality, and promoting knowledge and innovation (European Commission, 2022b).

One of the very important ten specific objectives is to encourage generational changes by supporting young farmers under the age of 40 who have become heads of their farms for the first time and are qualified in the field. According to the European Commission (2022c), the increased support to young farmers by the European Union results from concerns about the aging workforce, see the following chart mapping the age distribution of farmers in the European Union in 2016, which shows that young farmers make up only 11% of the farming population.
Figure 1. Age groups of farm heads, EU – 28, 2016

Source: own processing in accordance with the European Commission (2022c)

Unless the necessary generational changes take place, agriculture faces the risk of losing food security and reduced competitiveness. Young farmers are either granted income support or support through rural renewal funds. In the case of income support, this involves, for example, earmarking a certain percentage of payments, deciding on the maximum number of hectares to be paid for, choosing the method for calculating payments, etc. In the case of rural development funds, young farmers can benefit from grants, loans or guarantees related to the development of rural farms (European Commission, 2022c).

As one of the instruments to support young farmers within the new CAP, EU countries will be required to allocate at least 3% of their budgets to direct payments to young farmers, either in the form of income or investment support or start-up support (European Commission, 2022d).

In this context, the question arises as to how the funds from direct payments under the Common Agricultural Policy have been distributed to young farmers so far under the original rules of the Common Agricultural Policy, or how their support will change from 2023, both in the Czech and Slovak Republics. In order to answer this question, the following paper has been prepared and is divided into four parts. After the Introduction chapter, explaining the reasons for the defined objective of the paper, there is a Literature Review summarizing the conducted research and published studies on the given topic from recognized scientific databases. The third chapter presents the results in the area of interest. The main benefits are summarized in Conclusion, the last chapter.

2 Literature review

Nowadays, the European Union is facing a shortage of new farmers - this situation is partly caused by the low interest of young people in doing business in this segment of the national economy, and partly by the rapid aging of the existing population of farmers (Zagata & Sutherland, 2015). The EU CAP responds to this situation by introducing various measures to motivate new and especially young farmers. These support measures focus not only on the initial start of their farming activities but also on the subsequent structural adjustment to their business (Kontogeorgos et al., 2014).

As has already been mentioned, young farmers are supported in the European Union under Pillar 1 and Pillar 2 of the Common Agricultural Policy. Pillar 1 includes direct payments, which are higher for farmers aged under 40, and Pillar 2 includes the rural development program. It is within the rural development program that each Member State can determine its own extent of support to young farmers. According to Simpach (2018), some Member States have allocated funds through only one operation, M06, within Objective 2B Generational Renewal, but the majority have funded this objective through multiple operations (e.g., M01, M02 M16). "The amount of funds from the Rural Development Programme earmarked to support young farmers shows how important farmers are in the region. The percentage of farmers supported may indicate the extent to which each country is concerned about the problem of young farmers." For this reason, Simpach (2018) has compared the importance of supporting young farmers in the selected EU countries in terms of financial resources against the total budget of the Rural Development Programme in his paper. This comparison has resulted in the finding that the best situation is in Poland, where 5.3% of the RDP budget is allocated to Objective 2B (for M06).

This paper also continues the research of Brodzinksi (2019), who has sought to answer the question of whether young farmers benefiting from preferences under the Common Agricultural Policy are more willing to modernize farms they manage than other farmers. To answer this question, he conducted a study in 2018 involving two groups - one with 32 young farmers and the other one with 48 farmers aged 40 and over. Both groups ran development

farms with commodity-based production. In the sample of young farmers (who were surveyed), the average area of their farms was 31.47 ha, while the average area of the farms in the second group was 112.46 ha. This means that the older farmers owned 3.5 times larger farms compared to the young farmers. It seems logical to find that the young farmers worked alone, while the older farmers mostly employed hired workers. The result of the study is that in view of the high costs of modernizing production and, above all, the need to increase the scale of production by purchasing land, the further development of farms run by young farmers will be slow and evolutionary, as was the case with farms run by the farmers in the comparative group. Similar research was also published by Pechrova (2015). Her research is based on the European Commission´s assumption that subsidies should support business activities of young farmers, as they bring innovation to farms and achieve higher profitability. However, it is justified to examine the legitimacy of providing these subsidies as they are public financial resources. Therefore, she assessed the technical performance of young farmers and compared it with businesses managed by "non-young farmers". A better performance was identified in the group of young farmers (67.6% compared to 59.1% in case of the control group). However, this result also shows that young and other farmers are not statistically significantly different in terms of technical performance, which does not confirm the above assumption of providing support to young entrepreneurs in the agricultural sector.

Nevertheless, McKillop et al. (2018) point to differences in the overall population of young farmers as they examined differences in innovation between young farmers in Ireland. Their results show differences between real innovation on the farms of young farmers and what is theoretically considered important in professional circles. Young farmers differ in their innovation scores. This finding stems from different areas of farm management, be it overall efficiency, breeding, information technologies or performance monitoring.

The authors of the research also offer a solution to the identified situation - given the relatively small number of young farmers in many European countries (including Ireland), research and expanding organizations can develop specific programs, tailor discussion groups to, and target subject teaching at specific types of young farmers instead of the current general approach that fails to distinguish the interests of young farmers from those of the older generation. Therefore, agricultural education providers should take these differences into account to ensure that courses are comprehensive and targeted to stimulate innovation. In their paper, Munteanu et al. (2021) argue that young farmers are expected to develop more sustainable and profitable businesses. However, young farmers need to adopt a proactive management style and possess technical know-how in order to be able to overcome the current challenges in the agricultural sector. Therefore, these authors call for initial training of young farmers as it is essential for developing the basic skills and know-how necessary for agricultural business, while continuous learning is a must for identifying the managerial and marketing skills necessary for profitable, innovative and sustainable agricultural practices. The same conclusion is also drawn by Balezentis et al. (2020), who present a high demand for advisory services in preparing a business plan by young farmers, which indicates a low level of business administration and marketing skills. Unay-Gailhard and Bojnec (2021) also demonstrate a gap between male and female young farmers. According to their results, women (compared to young farmers) show more interest in environmentally friendly farming practices.

The study by Phiboon et al. (2019) is based on the assertion that many countries have support programs to help young people start their own business. "However, some of the programs have been criticized for not providing enough support, particularly because they do not sufficiently take into account the diverse profiles of young farmers." Their study therefore analyzes the profiles of young farmers, i.e., it examines the extent to which they use support programs. The outcome is that young farmers can be categorized into five types, which differ in terms of motivation, farming systems and involvement in farming. "Some farmers focused

on economic profitability, while other farmers considered environmentally sustainable farming practices important or were actively involved in other activities at home or village level. This wide range of objectives and situations meant different constraints during the early years of farming. The support programs helped farmers overcome their lack of farming knowledge and helped them integrate into rural communities, but the support they received in accessing land and capital was sometimes limited and often none at all." Therefore, to improve the support to young farmers, Phiboon et al. (2019) suggest taking into account the diversity of young farmers´ profiles and taking this into account not only when building capacity but also when gaining access to other types of resources.

The situation of young farmers, or, more precisely, strengthening their position for doing business is not only an issue of the European Union or the European continent, but this issue is addressed by authors all over the world. For example, Can & Engindeniz (2020) or Nainggolan et al. (2020) argue in their study that the sustainability of Arabica coffee business in the Simalungun region depends on young farmers who, as the next generation of farming enterprises, need special attention in order for agricultural products to be competitive in the global era. Hence, these authors conducted depth interviews among young farmers and found that the strategy of strengthening the role of young coffee farmers requires two components: driving and facilitating factors. Driving factors include, in particular, changes in non-market economic systems, changes in client patron systems, an open access to coffee processing tools, shaping the image of young farmers as active and critical agents, and the position of young coffee farmers as dynamic agents in building leadership and entrepreneurial character. Facilitating factors have been identified as follows: building a team, organizing young coffee growers by strengthening social capital, protecting the water and soil resource bases by implementing good agricultural practices, diversifying livelihood, opening market access, and information- and technology-based coffee advice and mentoring.

3 Methodology

This paper evaluates support to young farmers and provides the supporting arguments by reviewing recent studies from scientific databases. The analysis of support to young farmers is carried out for a period of five years (2015-2019), focusing mainly on the Czech and Slovak Republics. However, the authors have also sought to determine whether the situation in these two (historically very related countries) differs from that of the other Visegrad Group countries, and whether the situation differs from that of the EU founding countries (Germany, the Netherlands, Luxembourg, Italy, France and Belgium). Therefore, the data for the Czech Republic and Slovakia were also compared with those of the above-mentioned countries. The statistical yearbooks of the Common Agricultural Policy of the European Commission (Directorate-General for Agriculture and Rural Development) are the source of the data. The data for the European Union as a whole represent the aggregate of the 27 Member States (excluding the EC). MS Excel was used for the comparison.

The paper will result in the confirmation or refutation of two basic assumptions:

Assumption 1: There is no significant difference in the percentage of direct payments to young farmers from the total amount of direct payments between the Czech and Slovak Republics, i.e., the two countries have the same trend due to their recent common history and also tend to have the same methodology for calculating this support.

Assumption 2: There are no significant differences between the Visegrad Group countries and the EU founding countries. In other words, the authors presume that the two groups will show a similar trend in the percentage of payments to young farmers and, in particular, will follow a similar policy of calculating payments to farmers.

4 Results

The following table shows the absolute amount of payments to young farmers within direct payments in the EU as a whole and for the selected Member States - firstly the Visegrad Group countries, with the EU founding countries being listed below.

Table 1. Direct payments to young farmers in the entitlement period of 2015-2019 (in millions of EUR).

State/Year	2015	2016	2017	2018	2019
EU 27	304.4	340.3	367.3	526.9	567.4
Czech Republic	2.2	2.4	2.4	7.0	8.0
Slovakia	0.3	0.4	0.6	0.8	1.6
Poland	62.1	60.0	57.6	63.5	64.2
Hungary	9.5	11.4	12.7	12.1	12.7
Germany	36.1	45.8	50.3	64.4	72.9
Netherlands	10.8	13.00	12.4	13.8	12.9
Luxembourg	0.7	0.6	0.6	0.6	0.7
Italy	28.5	32.5	40.1	75.4	73.5
France	43.9	49.5	50.3	81.00	90.8
Belgium	7.3	8.00	8.4	9.3	9.4

Source: own processing in accordance with the European Commission (2022e)

The table above enables a visual assessment of the trend in the distribution of direct payments to young farmers. There is a very strong shift in the EU time series between the period of 2015-2017 and the period of 2018-2019, or rather in 2018 there is a steep increase in direct payments to young farmers by EUR 159.6 million. The steep increase is also visible for the Czech Republic and the two founding members of the EU - Italy and France. The Polish data also show a rise, but after two years when direct payments to young farmers were reduced. A gradual but annual increase can be identified for Belgium, Germany, and Slovakia. Fluctuations (i.e., alternating increases and decreases) are noticeable for the Netherlands and Hungary. Luxembourg is the only country with a relatively stable level of direct payments.

It follows from the above that it is not possible to find identical elements in the development of direct payments to young farmers within the V4 countries or within the group of founding members of the European Union.

If we were to primarily assess the Czech and Slovak Republics, the development is clearly different. While the level of direct payments to young farmers in the Czech Republic stagnated until 2017, there was a sharp increase in the following years compared to the Slovak Republic, where there was a gradual but steady increase. A more substantial increase can be identified only between 2018 and 2019.

As the absolute amounts of support from direct payments to young farmers are not comparable between the above-mentioned countries, the percentage of this amount in the total amount of direct payments of the selected countries will be further analyzed.
Figure 2. The percentage of payments to young farmers in the total distribution of direct payment expenditure of individual member states (%)

Source: own processing in accordance with the European Commission (2022e)

The graph clearly shows that the percentage of payments to young farmers in the total direct payments ranges from 0.1 to 2.1%. The upper limit results from the fact that national authorities of Member States are supposed to earmark up to 2% of the total income support to payments to young farmers under the original CAP rules.

The graph visually divides the analyzed countries into three levels. The first level of countries oscillates (especially in recent years) around the aforementioned limit of 2% of direct payments. The second level of countries does not reach this 2% limit despite a noticeable growth within the period of 2015-2019, and the third level could include the Slovak Republic, which represents the lowest level in the graph. Luxembourg, Poland, the Netherlands, and Belgium fall under the first level, as well as Italy in the last two years. The second cluster consists of Germany, Hungary, France and, in the last two years, the Czech Republic as well.

The Czech and Slovak Republics show the same trend only until 2017, after which the Czech Republic deviated considerably by increasing payments to young farmers. The graph also failed to identify the cluster of the V4 countries and the cluster of the EU founding countries, or rather both the V4 and EU founding countries are found in both visible clusters.

The above differences can be explained by the different policies chosen by the Member States to calculate the amount of direct payments to young farmers. These policies were published in a separate document by the European Commission for the whole EU in May 2016. An extract from this document concerning the Member States under analysis is presented in Table 2.

Table 2. Policies chosen by the selected Member States for calculating payments to young farmers.

Member state	Calculated as 25 % of the				with the max. limit of	As a lump sum amount per
	National average payment per ha	Single area payment	BPS flat rate	Average value of entitlements held by a farmer		
Czech Republic		x			90 ha/entitlements	N
Slovakia	x				28 ha/entitlements	N
Poland	x				50 ha/entitlements	N
Hungary	x				90 ha/entitlements	N
Germany			x		90 ha/entitlements	N
Netherlands	x				90 ha/entitlements	N
Luxembourg						x
Italy				x	90 ha/entitlements	N
France	x				34 ha/entitlements	N
Belgium	x				90 ha/entitlements	N

Source: European Commission (2016)

Table 2 presents the differences in the methodology for calculating payments to young farmers between the Czech Republic, Germany, Italy, and Luxembourg. Specifically in the Czech Republic, only beneficiaries of the Single Area Payment Scheme (SAPS) are thus entitled to the payment which is calculated by multiplying the value corresponding to 25% of the SAPS payment by the number of eligible hectares up to a maximum of 90 ha. The limit of 90 hectares can be identified for the majority of the countries analyzed. The only exceptions are France and Poland. The Slovak Republic has the lowest limit of only 28 hectares.

Again, the Czech and Slovak Republics do not use the same method of calculating direct payments to support young farmers, nor is there a common methodology within the group of V4 and founding Member States of the EU.

On the basis of the above, the authors have to reject both assumptions formulated in the Methodology chapter.

Nevertheless, the reformed Common Agricultural Policy, which will enter into force in 2023, allocates at least 3% of the budget to young farmers. As this rate has not been reached by any of the countries analyzed, it is clear that young farmers will actually receive higher payments, and these are the young farmers in the Czech and Slovak Republics who should experience the greatest change, as they are (according to Figure 1) at the very bottom of the support range.

5 Conclusion

The performed analysis of the support to young farmers through direct payments rejects both assumptions defined by the authors, i.e., the comparison of the Czech and Slovak Republics has not revealed the same trend of support development. The amount of direct payments to young farmers in the Czech Republic stagnated until 2017 and there has been a sharp increase in the following years (from EUR 2.4 million to EUR 7 million) compared to the Slovak Republic, where there has been a gradual but steady increase. A more significant increase in support from direct payments to Slovak farmers can be identified only between 2018 and 2019. Also, the method of calculating direct support differs between these two previously united countries, namely both in the basic value on which the calculation is based and in the hectare limit. The analysis has also not revealed any unifying elements common to the Visegrad Group countries or to the founding members of the European Union. The graphical representation of the percentage of payments to young farmers in the total distribution of direct payments divides the countries into three levels, and each level includes both the V4 countries and founding members of the EU. This finding therefore points to national concepts in determining the amount of direct support to young farmers.

Thus, an increase in direct support to the 3% limit will mean a significant increase in support to young farmers, with those from the Czech and Slovak Republics being the ones to experience the biggest change. This finding is also the only connecting point between the two (for a long time united) countries discovered in this paper.

Information and Knowledge Society in the Global Era of New Media and Technoference

Vladimíra Hladíková[1,*]

[1] University of Ss. Cyril and Methodius in Trnava, Faculty of Mass Media Communication, Námestie J. Herdu 2, 917 01 Trnava, Slovakia

Abstract

Research background: Current global trends include the information explosion, the constant use of digital technologies, new media and certain disruptive influences associated with them, which can be comprehensively described by the term technoference. In addition to the speed, availability and quality of information, knowledge and expertise play a key role in society. Terms such as the knowledge economy and the knowledge society have become global catchwords, which also bring with them certain risks in the field of education, such as the reduction of knowledge to results, the atomisation of knowledge or the weakening of linear, logical thinking.

Purpose of the article: The paper presents a brief overview of the state of contemporary society at the current stage of technological development with regard to its information and knowledge-based nature. The aim of the paper is to identify and examine the specifics of the information and knowledge society and to determine the differences between them. Emphasis is also placed on the possible negative consequences of these phenomena.

Methods: In particular, the author used analytical, inductive, deductive and comparative research methods.

Findings & Value added: The paper contributes to clear definitions of information and knowledge society. It highlights the importance of critical thinking and reflects on the possible risks associated with the topic presented.

Keywords: *information society; knowledge society; new media; technoference; risks*

JEL Classification: *I25; Z13; O33*

1 Introduction

An important popular notion of the 21st century is the term information. Therefore, their growth and expansion into all areas of the human world naturally caused a change in the overall character of society. With the continuous development of the world, technology and civilization, individual changes took place, from the gradual change of lifestyle through

---

* Corresponding author: vladimira.hladikova@ucm.sk

hunting, agrarian, industrial and technological revolution to the present day. Today's society is often referred to as an information society. It is mainly related to the huge expansion of new information and communication means, new media, and technologies, and undoubtedly to the expansion of information as such. We are of the opinion that it is the information society primarily linked to digital media and the Internet that represents the paradigmatic metamorphoses of individuals, society, and the entire human culture. This new situation delivers changes in all spheres of society's functioning, it is reflected in various scientific fields and disciplines. The information society represents an environment where information is of primary importance. Knowledge grows from information (and information is also a frequent product of knowledge), a knowledge society is created, the economic basis of which is in the global knowledge economy.

2   Methods

The main objective of the paper is to identify and examine the specifics of the information and knowledge society in the global era of new media and digital technology use at a time of technological interference. The author also focuses on the basic differences between the notion information and knowledge. For the topic to be examined comprehensively and systematically, several scientific methods were used, especially structured analysis and description of facts, as well as synthesis methods, logical, inductive, and deductive procedures for exploring the topic and fulfilling the set objectives. We proceeded to the critical processing and evaluation of domestic and foreign literary sources. One of the established objectives was to logically link all important elements related to the discussed issue to the final formulations of the conclusions. The subject is organized according to logical facts and deduction of the results of the analysis of professional scientific texts into a complex meaning unit that identifies the basic differences between the information and knowledge society in the current global era.

3   Results and Discussions

3.1 Information vs. Knowledge

Understanding information and knowledge, their mutual relations and hierarchy should be a basic competence in an information or educational society. However, for this we need to understand their basic units such as information and knowledge. The term information is a multi-meaning notion and accompanies humanity throughout the entire historical development of society. Especially in recent decades, there has been an explosion in the use of the term information, its meanings have changed, and today we understand it mainly in the context of digital technologies or computer technology. Currently, it can be described as one of the most important and frequented terms of various theoretical-scientific disciplines as well as practical fields, especially computer science, media studies, philosophy, sociology, economics, or management. It is obvious that there are innumerable quantities of data, quantities and knowledge, and their definitions vary from author to author. Several terminological confusions also arise between the terms information and knowledge (insight, know-how).

Galik (2015) characterizes information as an elementary unit of meaning, which is contextual. It means that its complete numerical calculation is not possible, as is the case with data in computers. On the contrary, the author defines knowledge as a higher level of information, which represents a complex of meaningfully arranged information. However, it is important and necessary to distinguish between information and knowledge - information itself

is not knowledge but is its premise and basis. In this context, we consider information as raw material, the processing of which creates knowledge. The result of information processing is knowledge that can influence our personality fund, enrich, or restructure it (Lei and Duan, 2021). Other definitions state that knowledge is a certain explanation of information. It is an insight that follows from the information, or rather a certain opinion about the given information. Knowledge gives a person the ability to put individual information into context - knowledge is thus contextualized information (Renze, 2019). The difference between information and knowledge can also be observed based on their ability to answer basic questions - information answers the questions who?, where?, when?, what?, while knowledge answers more precisely the questions why?, in what way?

Therefore, what constitutes the basis and fundamental essence of the education of a person? We believe that it is different knowledge, insights, and information. H. Meter presents the hierarchy of education as follows:

- data (unprocessed symbols that do not have meaning in themselves);
- information (data that has meaning through a relational connection; may or may not be useful);
- knowledge (useful information, only the question "how?" has meaning in this case);
- understanding (it is important to understand the causes and connections, in comparison to the question "how?" the question "why?" is more important);
- wisdom (this is the highest level of knowledge and includes visions of the overall connections between various, even very distant phenomena. Knowledge is acquired through an experience-verified system of values (Meter, 2020).

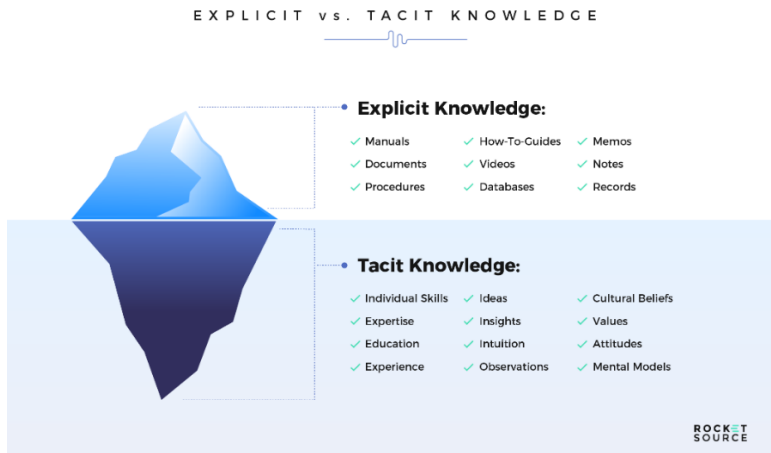
Wisdom is a combination of theory and practice, which can also include a person's complex experience with a system of values and ethical behaviour. We can therefore include, for example, tacit knowledge, which significantly contributes to human creativity and innovation, to wisdom as a broadly understood education. In knowledge management, we most often encounter the terms tacit - implicit and explicit knowledge, which form two basic groups of knowledge. Explicit knowledge can be understood as uniformly defined, codified, or structured, and it is possible to express them easily with letters, words, signs. It is similarly easy to communicate and share them in a formal language, as well as capture and represent them in documents, databases, or information systems. We can imagine them as knowledge recorded in books, articles, or other media, and it is also possible to transfer, store or share them. More complex, and more important for the category of wisdom, are implicit - tacit knowledge (i.e., quiet, silent). We can describe them as a opposition to explicit knowledge. It is yet unexpressed knowledge acquired through training or education, it is a hidden type of knowledge that we normally acquire through socialization with the environment and whose existence we often do not even know about. However, the problem arises when trying to externalize them, which is often very difficult, sometimes even impossible. That includes, for instance, an attempt to verbally describe a colour or written instructions for swimming or cycling (Asher and Popper, 2019; Ibidunni et al., 2022).


Figure 1. Explicit and tacit knowledge

Source : Explicit & Tacit Knowledge Iceberg Infographic. Retrieved from https://slidemodel.com /templates/explicit-tacit-knowledge-iceberg-infographic/

Thus, the basic determinant of education is meaningfully organized information, which, however, is already related to a large amount of tacit knowledge, experience, morality, as well as the ability of intuition and creativity - which we can summarily describe as wisdom. However, we do not consider it accurate to focus only on the understanding of education as a systematized body of knowledge that can be applied in practice. Developing wisdom can be related to the expansion and deepening the basic amount of knowledge. Sometimes even "useless" knowledge can significantly innovate established thinking patterns and bring new meanings and messages. In this context, Greenfield (2016) adds that wisdom requires a more extensive system of connections, while the associations made are based on an even wider range of experiences and individual memories, which allow us to assign more general values to things or events.

4 Information and Knowledge Society. Selected Risks of the Knowledge Society in the Context of Technological Interference

Information society as a concept enters the social sciences at the end of the 1970s. It finds its place not only in the field of sociology, where it serves as a term that covers new forms of communication and social behaviour, but also in the field of new technologies, from the development of which transformation mechanisms are derived, and in the political sphere, where the information society becomes the ideal to which countries should reach. The notion information society is said to have first appeared in Japanese. A group of social scientists used it to mark the era into which Japanese society at that time was entering. According to them, the sign of the information society was a quantitative but also a qualitative excess of information. In this context, we can also mention M. McLuhan, who in the 1960s developed his concept of an information society metaphorically called the global village. It was a form of "tribal" society in which creative dialogue using global consciousness recorded in computers prevails. It can be concluded that it was the medium of the Internet that gave McLuhan's visions regarding the global village a more concrete form.

The information society can therefore be characterized by using digital technologies, digital communication and especially digital storage, processing, and transmission of

information. Shevchenko et al. (2022) also agree with this theory, who define the information society as the connection of information, communication, and mass media technologies.

This term is one of the most frequent when discussing the current state and the general current situation of humanity. The path to the information society was accompanied by a technological revolution, which is based on the interconnection of information, communication, and mass media technologies (Roztocki et al., 2019). The result is, for example, a dramatic reduction in space and time constraints and an increase in access to a large amount of public information. Compared to previous technological waves, the impact of connected information, communication and media technologies is characterized by a wide area, miniaturization, digitization, and high speed of penetration into all areas of society or communication in general. These changes affected practically all areas: industry and services, public and private sector, the whole society at work and outside, education and entertainment in everyday life.

The current definition of the information society suggests that it is a situation in which work (or manipulation) with information is more effective than work with matter.

It is a society in which information is intensively used through modern information and communication technologies for its comprehensive development. In this context, it is also possible to define several possibilities and opportunities of the information society:

- increasing the quality of life through a greater selection of services and entertainment;
- better support for education and continuing education during an active career, support for the company's professional flexibility;
- new possibilities to implement people's creative abilities;
- increasing the company's ability to respond to changes in the structure of supply and demand for workforce qualifications;
- new possibilities of applying cultural traditions and identity of regions, elimination of remoteness of peripheral areas;
- more efficient and transparent state administration, closer to the citizen, operating with lower costs, higher share of citizens in public administration;
- more efficient business management and facilitation of the connection of producers and service providers with customers, increasing competitiveness; new services provided within telecommunications and new markets in the field of software (Abramova and Popova, 2019).

When analysing the information society, emphasis is often placed on its network character. It is especially the network that can be considered as a key feature of the information society. Therefore, this era can also be called "the age of network intelligence". The Spanish theorist Castells (2022) approaches the perception of the information society in a similar way, who refers to the information society as a network society. He states that networks constitute the new social morphology of our society. It is thus a new technical-economic paradigm, which manifests itself in the network logic of each participating system.

In the context of the information society, the term *knowledge society* is often used, sometimes they are also confused. As we have already demonstrated, information and knowledge are close to each other, but despite their seeming, external resemblance, it is necessary to differentiate them. For this reason, it is not correct if the term information society and knowledge society are equated. The idea of a knowledge society is based on the concept of an information society, its understanding continues in the form of an information society, but the priority of information is replaced by knowledge. The author of the term knowledge society is the American philosopher of Austrian origin Peter F. Drucker, who put this term into practice mainly in connection with the so-called knowledge economy. The emergence of the knowledge society was preceded by the enormous development of information

technologies as well as the process of informatization and computerization in the second half of the 1990s. Peter F. Drucker elaborated his theory in the work *Post-Capitalist Society* in 1992. The fundamental ideas of his work were gradually incorporated into the economies of the USA and the European Union, which resulted, for example, in the creation of a document known as the *Lisbon Strategy*. Its aim was to make the EU the most competitive and dynamic knowledge-based economy in the world by 2010, capable of sustainable growth, with more job positions and greater social cohesion. It can be stated that the knowledge-based economy is characterized by its globality, the exceptional use of human thinking and knowledge, materialized in technology in a remarkable way (Sira et al., 2022; Pacalajova and Kubinec, 2021).

If we talk about the knowledge economy, it is a description of the way in which several industries with a high technological level – for example, information and communication technologies, biotechnologies, nanotechnologies, etc. - as well as educational or scientific institutions contribute significantly to the creation of wealth in the country. In a broader sense of the word, we discuss a knowledge society, which requires a change in the functioning of principles in society (following economic life). The knowledge society therefore invests purposefully and actively in the development of the personal potential of each individual and develops its innovative capacity through the support of education, scientific or research activities. In this context, it is possible to summarize several basic principles of the knowledge society:

1. Knowledge is the most productive economic resource.
2. In a knowledge-based society, effective circulation of knowledge and not capital is ensured.
3. The inexhaustibility of the raw material of knowledge.
4. Knowledge is enriched by use and is therefore unique and inalienable.
5. Every human being is the owner of knowledge and can use it individually or socially (Hargreaves, 2022).

A knowledge society is a form of society in which, instead of information, priority is given to knowledge, know-how and insights as the most important and valuable aspect of capital. We consider the individual's ability to orientate in information sources, effectively search them and correctly interpret the information sought, put it into context, creatively process and create knowledge and insights from them as one of the elementary prerequisites for the existence and development of a knowledge society. If we talk about a knowledge-based society, it means that knowledge has become a decisive factor in the quality of life. A knowledge society is a society that enables open access to information and education, assumes the capacity of society members to absorb and interpret the information obtained, creates opportunities for using knowledge for qualified decisions and for proceeding to a qualitatively higher level of life (Perez Zuniga et al., 2018). The most valuable capital of the knowledge society is education and creativity. A knowledge society can be understood as a society in which the basis of social and economic coexistence is increasingly formed by individual and collective knowledge and their organization (Dovgal, 2021). It is a society in which knowledge is applied in all its areas, namely social, economic, cultural and others. Progress in these areas is achieved in the knowledge society mainly by applying knowledge to the effective use of social resources with the aim of improving the quality of life of society members and the environment. A fundamental increase in social knowledge is the first essential condition for the emergence of a knowledge-based society and its main feature. A person is the value for society from which everything else depends. It is a key subject of education. Today, education is becoming a significant element of the way of life, a life goal, the way of spending free time and a significant value (Ambrozova and Kaliba, 2019). Therefore, all requirements for the educational system and for the education of society stand, but also fall with the person. The central focus of the knowledge society is education and

knowledge sharing. Therefore, individual states should pay attention to the quality of their human resources, as well as place emphasis on increasing the level of education, qualifications, and ensuring appropriate retraining of the workforce. Educated people are more flexible and productive because they can use their potential more effectively or adopt new technologies.

The ability to create new knowledge and use it effectively is exclusively a product of a person's creative mental activity. We consider a comprehensive system of objectively true knowledge about nature, man, and society to be the basis of that part of social knowledge that can be used for the creation and functioning of a knowledge-based society. The responsibility of creating and constantly expanding this knowledge system is mainly fulfilled by science, therefore its support is another condition for the creation, existence and functioning of a knowledge society. In this context, it is possible to formulate several basic key conditions for the creation and effective functioning of a knowledge society:

- fundamental increase in social knowledge;
- permanent quantitative and qualitative development of human capital;
- support of science;
- increasing social cohesion in society;
- implementation of an economic policy supporting innovation.

One of the conditions for the development of a knowledge-based society is the use of information and communication technologies in production, education, as well as in the everyday life of a person (Sagikyzy et al., 2020). The introduction of information and communication technologies and the streamlining of processes through their use contribute significantly to a much higher efficiency and effectiveness of the implementation of all elements of the knowledge society. Santa (n.d.) formulates several recommendations for practice related to education in the information and knowledge society:

- to educate a flexible and competitive workforce capable of applying itself in the conditions of the information and knowledge society;
- provide education enabling residents to use the benefits that computerization brings;
- to raise the level of education so that it is competitive in terms of quality and forms with the developed countries of the EU;
- to innovate the content and form of teaching based on demand and requirements, the use of information and communication technologies;
- create conditions for obtaining and maintaining quality teachers at all levels of schools;
- to ensure constant innovation of the population's knowledge through lifelong education;
- in accordance with the principle of equal opportunities, ensure education in the field of computerization for all;
- ensure the corresponding information and communication infrastructure.

At the same time, it is possible to discuss whether and to what extent the knowledge society benefits people and society. Knowledge places high demands on people's abilities, on their ability to think critically and judge (Khamidov, 2017).

It can be confirmed that we live in the digital age. Mastering digital technologies, computers, and the Internet – to be informationally and digitally literate means having power in your hands in today's world and society. However, several theorists (Clinton, 2019; Varga, 2020) also point to the negative consequences of the use of new media and the Internet, for example in the context of misinformation, the spread of fake news and a generally low level of education. Electronic communication and digital media innovate the traditional understanding of space and time and significantly change the ways of human thinking,

behaviour, perception, experience, and education. Connecting to the Internet via a smartphone or tablet allows owners to continuously interact with their device and offers the ability to be always available – online in cyberspace (Bezakova et al., 2021). Through this constant connection and perceived accessibility, mobile devices provide endless opportunities for distraction.

In this context, a current phenomenon related to communication in the digital environment can be mentioned - the so-called technological interference (technoference). These are constant disruptions to interpersonal interactions and can interfere not only with relationships, but also weaken attention, ability to concentrate, accuracy, precision and other factors that are related to education. The main symptoms of such behaviour include, for example, interrupting offline conversations, constantly checking online content and notifications (for example, during a family dinner), feelings of disturbance that an individual experiences if his or her partner checks his or her device during free partner moments (even if the partners at that time did not interact with each other), etc. In general, we can summarize that technoference is any disruption of a real event that is caused by modern technologies and digital devices.

A suitable example is the research of Bauerlein (2010) who investigated American high school and university students, their skills and knowledge in the context of using electronic media. Research results have shown that the students' ability to read and interpret text is declining dramatically, which is related to a simple thing, namely excessive use of electronic media, especially Internet communication via mail, chat and Facebook, and minimal reading of books. Based on the decline in reading, Bauerlein found that there was also a decline in knowledge, which the author perceives as a great risk for the entire globalized society, while digital disruption - technoference - plays an important role. In this context, Galik (2014) also draws attention to several risks of the knowledge society, such as reducing knowledge only to results or expressible knowledge or atomized knowledge, the weakening of a logical, linear way of thinking or the weakening of a person's relationship to the past and the future. It can be stated that the digital revolution touches most spheres of human life. Although we consider information, knowledge, and insights to be the basis of education, we must not forget that it is the technologies, especially media that we use, that change and influence our thinking and cognition.

New cognitive habits under the influence of technoference can have different structural forms, such as network arrangement, non-standard links between information, or interrupted information flow, especially by entertaining information. It is therefore necessary to appeal to the continuous development of critical thinking, which is one of the key competencies of a globalized knowledge society. Critical thinking represents an ability that is a prerequisite for attention, caution when searching for, using and interpreting information. The current (digitalized) society can only progress successfully and efficiently and rightfully bear the status of a knowledge society based on the application of critical thinking, differentiation between information, facts, opinions, and knowledge, together with the awareness of possible negative consequences related to understanding (education) and wisdom.

5 Conclusion

Information can be viewed as any data that has an abstract character and is accessible to human perception. Knowledge, on the other hand, is transformed from information in the process of human cognitive activity and represents formulated judgments, concepts or principles that are available for transmission in the process of communication. Thus, the notions of information and knowledge are not equivalent, and information cannot be recognized as knowledge until a person processes it through mental operations.

In the context of globalization, information technology, digital media, and technological interference, we should not overestimate the importance of information exchange in modern society. Although information is a tool for creating knowledge, it is not knowledge itself. In the absence of healthy and critical thinking skills, as well as the necessary educational foundations, information may remain just a mass of bland data, or the basis for manipulative techniques of the media, politicians, or other power elites.

Abstract

Research background: Slovak companies are located in an environment characterized by increasing market openness and economic integration. Competition is constantly intensifying and uncertainty in the business environment is increasing. As customer demand is increasing, it is necessary to respond quickly and accurately. Businesses try to cope with all the changes and turn them into their own competitive advantage.

Purpose of the article: The aim of this article is to analyse the competitiveness factors of Slovak forest based industry. Knowing the current situation in the industry can lead to an improvement in its economic performance.

Methods: The paper is focused on definition of factors influencing competitiveness, which are divided into external and internal factors. To achieve the main goal, a review of the literature was made. A method of the research is a systemic, comparative and logical analysis of factors determining competitiveness of Slovak forest based industry.

Findings & Value added: Based on the literature review, internal and external factors for increasing competitiveness are identified forest based industry.

Keywords: *competitiveness, forest based industry, market factors*

JEL Classification: *L21; M21; O12*

1   Introduction

Economic globalization has provided numerous opportunities for many manufacturers to participate in international trade and foreign direct investment. The operating environment of the forestry sector is becoming more complex and maintaining competitiveness is more difficult (Korhonen et al., 2017). Recent years have witnessed repeated waves of deglobalization that have adversely affected global supply and value chains (Su et al., 2020). The current business environment is characterized by high competition, uncertainty, growing customer demand, to which it is necessary to respond quickly and accurately. Businesses try

to cope with all the changes and turn them into their own competitive advantage (Belyaeva, 2018).

Competitiveness as a concept has several definitions. Theories dealing with competitiveness were derived from Adam Smith's theories of international trade, adapting as other influencing factors emerged over time and affected competitiveness at the company, regional or country level (Dima et al., 2018). OECD offers general definition of competitiveness: "the ability of companies, industries, regions, nations or supranational regions to generate, while being and remaining exposed to international competition, relatively high factor income and factor employment levels on a sustainable basis" (Hatzichronoglou, 1996). Esser et al. (1996) proposed the concept of system competitiveness, which consists of levels:

- Macro – observation of state policy affecting the macroeconomic environment,
- Meso – are the structure and political actions supporting the business of enterprises,
- Micro – directly related to the functioning of the enterprise.

Many authors dealt with the concept of competitiveness at the business level. Basically, it can be defined as a firm's ability to design, manufacture and market products better than those offered by the competition, taking into account price and non-price qualities (Korhonen et al, 2017). It is the ability of an economic entity to assert itself in economic competition with similar economic entities. Beneš (2006) understands competitiveness as a reflection of competitive advantages determined by specific market situations. Oral (1999) links competitiveness with the level of productivity. The existence and growth of the company's competitiveness are largely determined by the field of business and the nature of the company's production. According to Módos (2001), company's competitiveness is connected to profitability. Competitive enterprise is capable of achieving profit in the long-term time horizon when performing individual activities, as well as maintaining or expanding its position on the domestic and foreign markets. Freebairn (1986) states that competitiveness is an indicator of the ability to provide goods and services at a place and time so that customers can purchase them at prices that are better than those offered by other potential suppliers.

Porter et al. (2006) identified competitiveness factors as the level of employee education, the source of competitive advantage, the willingness to delegate authority and the innovative capacity of the enterprise. At the highest stage of development based on innovation and services, customer orientation and the use of marketing come to the fore. The implementation of information technologies is changing the nature of the classic competitive environment, a new type of competition was created, which is called e-competition. An important factor in the growth of the company's competitiveness is ensuring the improvement of current production, increasing the utility value, functionality and simplifying control while simultaneously reducing production costs (Grznár, Szabo, 2002). In the transition to production with higher added value and a higher share of sophisticated work, investment in research and development is therefore emphasized as another of the main factors.

Chavarro et al. (2018) published the Green Book 2030 on the National Policy on Science and Innovation for Sustainable Development and defines innovation as a decisive factor of competitiveness, which manifests itself in the form of: renewing and increasing the range of products and services and relevant markets, the emergence of new methods of production, supply and distribution, introducing changes to management, work organization, working conditions and workforce know-how. Chatzoglou and Chatzoudes (2017) emphasize that businesses with a high level of innovation achieve better competitive advantages. The introduction of new products or services can bring higher value for the company's customers, especially when its competitors cannot provide the same range of products or services. Innovation in business processes can reduce production time or service delivery time and again provide added value to existing (or new) customers. Moreover, the more innovative an

organization is, the more it is possible to develop and successfully implement new strategies that face negative fluctuations in the external environment.

Voinea and Simionescu (2005) identified a strong positive correlation between competitiveness and the existence of specialized research and development departments in companies. Cantwell (2003) emphasizes inter-enterprise cooperation on the creation of knowledge and innovation. With increasing technological complexity, the importance of human capital increases. Businesses often say that people are their most valuable asset. Surveys among top managers confirm that the development of human capital is rarely mentioned among the highest priorities. According to Ravindran (2004), the most mentioned are increasing sales, reducing costs and research and development costs.

Parobek et al. (2016) analyzed the competitiveness of Slovakian wood and semi-finished wood products. Using modified Balassa index and comparative price level index the authors found that the abundance of forest resources and competitive prices determine the comparative advantage in industrial coniferous roundwood trade for Slovakia. The Slovak forest based industry is located in an environment characterized by increasing market openness and economic integration. This has the effect of increasing the importance of mutual comparison of individual companies, countries and regions. In order to successfully ensure the long-term progress of companies and their competitiveness, it is important to objectively evaluate the current situation of the industry. The paper is focused on the research of specific factors influencing the competitiveness of enterprises in forest based sector in Slovakia. It explains the factors affecting the competitiveness of companies and provides information on the competitiveness of the selected industry.

2   Methodology

The aim of this article is to analyse the competitiveness factors of Slovak forest based industry. Knowing the current situation in the industry can lead to an improvement in its economic performance. At the company level, factors are divided into internal and external. To achieve the main goal, a review of the literature was made. A method of the research is a systemic, comparative and logical analysis of factors determining competitiveness of Slovak forest based industry.

The methodological approach was as follows:
- Definition of the concept of competitiveness.
- Review of the literature on competitiveness in the forest-based sector.
- Two main areas of main factors were identified – one of them the internal factors competitiveness, another one its external factors.
- Four factors were identified within the internal area and three factors within the external area.

Based on the literature review, internal and external factories were identified, taking into account the forest based sector. The evaluation was based on external and internal influences on competitiveness. The degree of influence on the external and internal factories was determined.

External factors come from the surrounding environment, they are independent of the company. These factors are related to the state policy, the market mechanism and the overall economic situation in the country. On the other hand, internal factors are related to company's financial condition, physical resources, intellectual capital, organizational structure, adopted development strategy, management methods, entrepreneurship, innovation, the quality of the offered products and services (Walczak, 2010). Considering the specific character of business conditions in Slovakia, we paid attention to factors related to the forest-based sector.

3   Results and discussion

Firm-level competitiveness has been identified to be driven by tangible and intangible factors such as cost efficiency, innovativeness, and quality, as well as socially focused issues such as ethical standing, social (or environmental) responsibility, and working conditions of employees (Castro and Roldán, 2013). According to Zhelev (2013) European manufacturers have as main factors of competitiveness their advanced skills, quality and design, which generate greater added value. However, Slovakia's comparative advantage, for instance in case of sawnwood production, is a higher share of exports compared to imports. It is necessary to increase the production of products with higher added value even at the cost of comparative disadvantage (Parobek and Slašťanová, 2020).

According to the literature review, four internal factors were identified – Firm-level strategy, Cost efficiency, Innovativeness, and Workforce qualification (see Table 1). Korhonen et al. (2017) show that strategies and firm characteristics related to innovation and differentiation provide the key for understanding competitiveness at the firm level. Cost efficiency, which increases the competitiveness in company was confirmed in several research studies (e.g. Vokurka et al. 2002, Tahvanainen and Anttila, 2011). These authors also emphasised the essence of supply chain management focused on delivering the right product at the right time at each level within the supply chain. This requirement is defined by its quality, dependability, flexibility, agility, and efficiency as necessary capabilities for achieving this goal. The priorities should not be considered as tradeoffs for each other, but rather as complimentary and cumulative. All of these capabilities are necessary for value to be delivered to each customer at each level in the supply chain. Innovativeness is the innovations that belong currently among the factors that have the greatest influence on increasing productivity and thus also the competitiveness of businesses (Ciocane and Pavelescu, 2015; Cantwell, 2009). Kajanus et al. (2014) illustrate that the profitability of the companies was negatively correlated with the amount of enterprises' own risk funding, but positively correlated with the number of new products that have entered into the markets and the share of exports. Workforce qualification idea was also confirmed and elaborated by Lentner (2007), whose study clearly showed that alongside a stable environment for public finances, modern education and healthy highly skilled workforce are also prerequisites for national economic competitiveness. Kocianová et al. (2022) mentions that more than a half of woodworking and furniture enterprises consider a lack of qualified workforce and increasing intensity of competition to hinder their development along with specific problems arising from the nature of family business, which is the underestimation of the issue of succession.

Table 1. Factors affecting competitiveness of companies in the forest based sector

Competitiveness factors	
Internal	*External*
Firm-level strategy	Environmental concerns
Cost efficiency	Bioeconomy strategies
Innovativeness	Customer demand
Workforce qualification	

Source: own processing

External factors represent those factors that companies do not have control over and can affect their competitiveness. The external environment of the sector is currently connected with the need to respond to environmental challenges and issues of sustainability. An important factor of future change for the forestry sector is related to ongoing structural changes, the implementation of national and international bioeconomy strategies. This may

result in new opportunities for the traditional forestry sector. On the other hand, there are also new risks if companies do not adapt to the changing operating environment (Korhonen at al., 2022). In this context, the importance of innovation is emphasized. A competitive forest based industry brings many benefits to society and the national economy. Studies suggest that innovation can be fostered through collaboration through clusters. One of the main goals of business clusters is to create competitive advantages Among the main drivers of cooperation in forestry and woodworking are: cost reduction, support of competitiveness and environmental sustainability. In clusters, companies constantly compare their achievements with others, which stimulates positive competition, innovation and increased productivity (Weiss et al., 2017).

The three external factors were identified in the forest based sector. Environmental concerns, use of resources, compliance with environmental legislation, management of its significant direct and indirect environmental aspects increase industry competitiveness. (Slašťanová, 2021; Dechezleprêtre and Misato, 2017). Maťová and Kaputa (2018) came up with findings of their research, that most of the active architects do not propose wood as a construction material and prefer substitute materials on a silicate base, especially in cases of civil and industrial buildings. In Slovakia, mistrust continues to be found towards wooden constructions where fire resistance remains the most negatively perceived property of wood. In bioeconomy strategies, using modified Balassa index and comparative price level index it was found that the abundance of forest resources and competitive prices determine the comparative advantage in industrial coniferous roundwood trade for Slovakia (Parobek et al., 2020). Customer demand and the intensified demand for ecological materials increases the interest of customers in buying wood, which increases the demand of companies and thereby increases competitiveness (Xu et al., 2013). Loučanová and Olšiaková (2020) state that Slovak consumers are rather traditional what is reflected in their preferred type of building construction. Only university educated consumers and respondents from the lowest age category present higher interest in wood houses, that is connected with their properties such as type of construction, fire safety, housing costs, quality, thermal insulating properties and lifetime.

4   Conclusion

Globalization affects the economic and social environment, and significantly increases the need for companies to increase their competitiveness in the market. It is therefore essential for businesses to face these challenges and focus on promoting innovation, adapting to customer needs and creating market advantages. The wood processing industry has the potential to achieve high competitiveness on international markets, create an active trade balance and contribute to economic growth of the sector and country. Knowledge is the place to begin of 'everything' and of all of the elements of competitiveness. On the premise of knowledge, the concept of innovativeness is created from competitiveness factors, understood as new products, services, processes at what time on which marketplace and how. From the results of the literature review, we have identified four internal factors: Firm-level strategy, Cost efficiency, Innovativeness, Workforce qualification. External factories have been identified as: Environmental concerns, Bioeconomy strategies, Customer demand. When supporting the aforementioned elements of competitiveness, it is necessary to observe the principle of environmental protection, which is a prerequisite for business and development strategies.

Abstract

Research background: This paper addresses the issue of e-commerce and its impact on shopping behaviour and consumer preferences. The paper further specifies the advantages of e-commerce, factors influencing shopping behaviour and decision-making and the impact of the COVID-19 pandemic on online shopping.
Purpose of the article: The main goal of this paper is to find out whether there are statistically significant associations between the feeling of safety when shopping online and shopping online using a smartphone.
Methods: Analytical data processing took place in two chronological parts. The first part points to the rough findings of the research and descriptive statistics. The second part of the analysis examines deeper relationships through inductive statistics. Due to the established hypothesis and the nature of the data, the second part made use of the Kolmogorov-Smirnov normality test and the Spearman correlation test.
Findings & Value added: The research results showed statistically significant associations between the frequency of shopping using a smartphone and the feeling of safety when shopping via the Internet. The results point to the fact that the safer consumers feel in the online environment, the more they are likely to shop using mobile communication platforms.

Keywords: *E-commerce. Consumer behaviour. Shopping behaviour. Consumer preferences*

JEL Classification: *M30; M31; M37*

1 Introduction

E-commerce means the purchase and sale of goods and services on the Internet. In addition to buying and selling, many people use the Internet as a source of information to compare prices or check the latest products on offer before making a purchase (Kumar 2014). E-commerce is a tool that helps develop new forms of business. An online store is open 7 days

---

* Corresponding author: richard.fedorko@unipo.sk

a week, 24 hours a day and does not require any special-purpose premises, salespeople, complicated accounting systems or stores in every country. An online store is available to everyone despite geographical location and without any time constraints. When shopping online, consumers do not need to leave the house to buy products they like, all they need is to click the "buy" button and the shipping company delivers the desired item directly to their home (Išoraitė and Miniotienė 2018). Kita et al. (2017) argue that marketing communication taking place online has a significant impact on consumers' choices and decisions to purchase products online. Online store or e-shop could be defined as a selling point that mainly offers goods and services based on available catalogues or organized product categories. An online store accepts an order placed by a consumer, mediates payment, provides various information about products or services, and handles complaints (Zamazalová et al. 2010). Electronic business's biggest advantages in the current world of technological and economic changes include (Commerce Mates 2022): Faster shopping process: e-commerce has sped up the entire shopping process. Consumers no longer need to visit brick-and-mortar stores as they can shop while sitting at home. E-commerce saves time, makes transactions faster, and eliminates operating costs. As a result, the total operating costs of businesses have been reduced. E-commerce has eliminated the need for businesses to open brick-and-mortar stores. Running a store is a huge expense in terms of rent, utilities, miscellaneous bills, and staff salaries. E-commerce saves all these expenses as it runs all business activities through a website or e-shop. Personalization of the shopping experience: E-commerce allows consumers to enjoy a personalized shopping experience. Consumers can search for and browse a wide range of products of their choice and in line with their needs without any restrictions. Online stores show products to consumers according to their interests and their location. Available 24/7: Online shopping is available 24 hours a day, 7 days a week. This is one of the main advantages of e-commerce. Consumers can browse online products at any time. Unlike brick-and-mortar stores, there are no official opening and closing hours. Unlimited connectivity: Online businesses can reach and connect with consumers in remote locations without geographical limitations (Lins &Aguino 2020). Consumers can place their orders from any location and have them delivered to their place of residence. Detailed product information: Consumers can get detailed product description online to compare the viewed product with other products and make an informed decision. Gaining customer insights: Online shopping has made it easier for a business to retarget its customers. Thanks to e-commerce, businesses acquire a lot of information about their customers when they shop online. Customers may be contacted by businesses from time to time, via personalized emails, messages, coupon, and promotional discounts offers. Steven et al. (2014) perceives consumer behaviour as the study of the processes involved when individuals or groups select, purchase, use, or dispose of products, services, ideas, or experiences to satisfy needs and desires. Businesses and organizations rely on knowledge of consumer behaviour, needs and desires. Ryantika and Hidayat (2020) identify cultural, social, personal, and psychological factors as four major influences on consumer purchasing behaviour, and these factors allow consumers to develop preferences for products and their brands. Although they note that these factors are not directly under the control of marketers, marketers are advised to gain a better understanding of them as this knowledge will help them create marketing mix strategies that appeal to their target markets' preferences (Kennett-Hensel 2012). Before the final purchase of a product or service, customers make decisions based on the following general factors (Bhasin 2019): Product price is the first thing almost 80% of consumers study before buying a product as every consumer has their own budget and they usually tend to spend within the budget unless they get some extraordinary quality for the slightly higher price. Experience – nowadays everyone is busy and wants to buy products that are readily available. The market is full of alternatives to particular products. Therefore, it is important that the shopping experience as well as the quality of the product is excellent. Product design should be

attractive (Labanauskaite et al. 2020). Functionality – the product should have all the functions the consumer expects when buying. Convenience – the product and services should be convenient for consumers. Otherwise, they will not buy them. Reliability – the product should be reliable and should always meet the consumer's needs. Compatibility – the product should be compatible with other products that the consumer is already using. The COVID-19 pandemic was not only a health crisis, but also an economic one as it has significantly affected societies and economies. The COVID-19 outbreak has changed the way we work, communicate and shop more than any other event of this decade (Despin 2020). As can be seen from the analysis of economic data on sales, this dramatic situation has significantly influenced the attitudes and behaviour of consumers. According to a study conducted by the Nielsen Company, the COVID-19 pandemic has led to a globally manifested change in the level of spending related and consumer behaviour (Nexcess 2022). The sale of necessities skyrocketed as consumers prioritised the most basic needs, including food, hygiene products and cleaning products. As Italy was the first country in Europe to have a hands-on experience with COVID-19 (from March to April 2020), the behaviour of consumers changed drastically. Consumers tended to focus on purchasing of essential goods, especially those deemed to prevent the spread of the virus, such as protective equipment and disinfectant gels (Cannito et al. 2021). The pandemic has completely changed consumption patterns, e.g., reduced sales of some product categories (e.g., clothing) and higher sales of other product categories (e.g., entertainment products) (Degli Esposti et al. 2021, Vysekalová et al. 2011; 2012). The perceived risks of COVID-19 can negatively influence the behavioural intentions of consumers (Troise et al. 2021), and lead to changes in people's behaviour and consumption patterns (Brewer and Sebby 2021). In a pandemic context, the perceived risk and the threat of contagion influenced consumer behaviour changes, emerging a greater preference for using technologies to socially distance themselves from other people (Kim et al. 2021). Consumers' electronic shopping behaviour is evolving at a rapid pace, online payment methods are becoming more common, more people are shopping via mobile phones, and, ultimately, consumers are more willing to use e-commerce than they used to be. Globally, more than four out of five consumers bought goods online in 2020. Online shopping has become second nature to many people in recent years and shows no signs of slowing down.

2 Methodology

The main goal of this paper is to find out whether there are statistically significant connections between feeling safe when shopping online and shopping online via a smartphone.

Based on the set goal, the following research question was formulated:
- Are there statistically significant associations between feeling safe when shopping online and shopping online via a smartphone?

Based on the above research question, the following research hypothesis was formulated:
- We hypothesize that there are statistically significant associations between feeling safe when shopping online and shopping online via a smartphone.

The research carried out for the purposes of the paper can be defined as primary, interdisciplinary and quantitative. The inputs to the analyses were obtained through the implementation of primary research using the questionnaire. Data collection via an electronic questionnaire took place in the month of June 2022. The link to the electronic questionnaire was distributed via the relevant Facebook pages and e-mail (private database of the authors). The research sample was selected based on the availability and willingness of participants to participate. The research sample consists of 421 respondents. Analytical data was processed in two parts. The first part points to the rough findings of the research and descriptive

statistics. The second part of the analysis examines deeper relationships through inductive statistics. Due to the established hypothesis and the nature of the data, the second part made use of the Kolmogorov-Smirnov normality test and the Spearman correlation test. Each of these tests was carried out at the level of the hypothesis in question in accordance with the nature of the specific data. The statistical analysis was carried out in the SPSS 22 program.

The object of research are respondents of the following generations:

Table 1. Age distribution of respondents by generation

Generation	Year of born
C	(2001 – 2009)
Y	(1984 – 2000)
X	(1964 – 1983)
S	(1963 and earlier)

Source: Young (2017)

Regarding the age groups, the paper follows the methodology of Miles Young (2017) from Ogilvy & Mather, which imposes the following classification: Generation C, or Centennials, are currently between the ages of 13 and 21, Generation Y, or Millennials, are currently between the ages of 22 and 38, Generation X, or Baby Boomers, are currently between the ages of 39 and 58, and Generation S, or Snow Flakes are currently 59 and older.

Table 2. Representation of respondents by generation

	Number	%	Cumulatively %
Generation C	42	9.9	9.9
Generation Y	151	35.9	45.8
Generation X	173	41.1	86.9
Generation S	55	13.1	100
In total	421	100	

Source: own elaboration

The largest age group of respondents was Generation X (respondents born between 1964 and 1983 (N=173; 41.1%)). Generation Y (1984 – 2000) was represented by 151 respondents, or 35.9% of the research sample. Generation S (born in 1963 and earlier) was represented by 55 respondents (13.1%). The youngest group of respondents, Generation C (2001-2009) was represented by 42 respondents (9.9%). The research sample consisted of 421 respondents, of which 270 (64.1%) were women and 151 (35.9%) were men. The gender composition of the research sample reflects the fact that women are generally more willing to fill in questionnaire surveys. As the respondents were selected based on availability and in the research, certain disproportions compared to the general population in Slovakia were expected. The same applies to disproportions in terms of regions of the Slovak Republic which were caused by a narrowly focused research sample (the questionnaire was primarily filled out by respondents from the author's private database primarily residing in Kosice (N=147; 35%) and Presov region (N=65; 15.4%). Together they made up almost half of the respondents.

3 Results

This chapter presents research results in easy-to-read tables using descriptive statistics.

Table 3. Frequency of online shopping via smartphone

	Number	%	Cumulatively %
1 – I don't shop	50	11.9	11,9

2 – Very rarely (several times a year)	41	9.7	21,6
3 – Rarely (several times in half a year)	51	12.1	33,7
4 – Sometimes (several times in 3 months)	54	12.8	46,5
5 – Regularly (several times a month)	95	22.6	69,1
6 – Often (several times a week)	76	18.1	87,2
7 – Very often (at least once every 2 days)	54	12.8	100
In total	421	100	

Source: own elaboration

Most of the respondents (N=95; 22.6%) shop online using a smartphone regularly (several times a month). 76 respondents (18.1%) shop online via smartphone several times a week. 54 respondents (12.8%) shop online via smartphone several times in 3 months, and the same number of respondents state that they do so very often, or at least once every two days. 51 (12.1%) respondents shop online via smartphone several times in six months. 50 respondents (11.9%) do not shop online via smartphone. 41 respondents (9.7%) stated they shop online via smartphone only a few times a year.

Table 4. Frequency of online shopping via smartphone

	Number	%	Cumulatively %
1 – I strongly disagree	24	5.7	5.7
2 – I do not agree	29	6.8	12.5
3 – I partially disagree	42	10.0	22.5
4 – I neither agree / neither agree	69	16.4	38.9
5 – I partially agree	94	22.3	61.2
6 – I agree	130	31.0	92.2
7 – I strongly agree	33	7.8	100
In total	421	100	

Source: own elaboration

Most of the respondents feel safe when shopping online (N=257; 61.1%). 69 respondents (16.4%) took a neutral attitude towards the feeling of safety when shopping online. 95 respondents (22.5%) do not feel safe shopping online.

3.1 Verification of the research hypothesis

The research hypothesis was formulated in the introductory chapter of the paper. The hypothesis was verified in this subchapter. The verification process provides a probabilistic model of accepting or rejecting a presumed proposition.

H: We hypothesize that there are statistically significant associations between feeling safe when shopping online and shopping online via a smartphone.

Table 5. Descriptive statistics - shopping frequency using a smartphone

N	421
Average	4.299
Median	5.000
Std. deviation	1.8975
Skewness	-.328
Kurtosis	-1.019
Range	6.0
Minimum	1.0
Maximum	7.0

Source: own   elaboration
Figure 1. Descriptive statistics - shopping frequency using a smartphone

Source: own elaboration

Table 6. Descriptive statistics - feeling safe when shopping

N	421
Average	4.667
Median	5.000
Std. deviation	1.6165
Skewness	-.691
Kurtosis	-.356
Range	6.0
Minimum	1.0
Maximum	7.0

Source: own elaboration
Figure 2. Descriptive statistics - feeling safe when shopping

Source: own elaboration

The results in Tables 5 and 6 and Figures 1 and 2 show that on a scale from 1 - the lowest frequency to 7 - the highest frequency, the average value of the frequency of shopping using a smartphone was 4.23 points. Furthermore, the results show that on a scale from 1 - the least safe to 7 – very safe the average value in terms of feeling safe when shopping online was

4.67 points. The Kolmogorov-Smirnov normality test was used to obtain knowledge about the normality or abnormality of the data distribution, as this information was necessary to verify the hypothesis.

Table 7. Normality test

	Kolmogorov-Smirnov		
	Statistic	df	Sig.
Frequency of shopping using a smartphone	.178	421	.000
Feeling safe when shopping online	.192	421	.000

Source: own elaboration

Since the normality test shown in Table 7 found that the data do not show a regular distribution pattern, non-parametric tests will be used to test the hypothesis instead. The aim of the hypothesis in question was to examine whether there are statistically significant associations between the frequency of shopping using a smartphone and the feeling of safety when shopping online. After considering the tests of normality of the data distribution and the nature of the variables, the non-parametric Spearman correlation test was used to analyse the hypothesis.

Table 8. Spearman's correlation test hypothesis

Spearman´s rho	Correlation Coefficient	.596
	Sig. (2-tailed)	.000
	N	421

Source: own elaboration

Based on the results shown in Table 8, it can be concluded that there are statistically significant associations between the frequency of shopping using a smartphone and the feeling of safety when shopping online. Therefore, the hypothesis in question has been accepted.

4 Conclusion

E-commerce is the process of buying, selling, transferring, or exchanging products, services or information through computer networks and the Internet. E-commerce and the use of the Internet in various industries benefit both consumers and businesses, as it enables the faster, easier, more convenient, and more flexible provision of goods and services. In addition to providing goods and services, the Internet also serves as an important promotional tool. Moreover, the Internet has become an important communication tool for businesses. Today, online communication tools are inexpensive, provide instant international reach, offer great real-time feedback, and can reach millions of people for whom the Internet is the centre of virtually all communication.

Based on the research discussed hereunder, it can be concluded that online shopping is important for most of the respondents (64.7%). Most of the respondents (67%) intend to shop online soon. 60.2% of respondents feel safe when shopping online. As much as 67.2% of respondents have a positive experience with online shopping.

Most of the respondents (26.1%) shop online several times a month. 19.7% of respondents shop online several times a week. 69 respondents (16.4%) shop online several times in 3 months. 14.3% of respondents (60 respondents) shop online only a few times in six months.

37 respondents shop online several times a year. 8.3% of respondents shop online very often, or at least once every two days. Only 27 respondents (6.4%) do not shop online. Most of the respondents (22.6%) shop online regularly (several times a month) using a smartphone. 76 respondents (18.1%) shop online using smartphones several times a week. 54 respondents (12.8%) shop online via smartphone several times in 3 months, and the same number of respondents stated they shop online via smartphone very often, or at least once every two days. 51 respondents shop online via smartphone several times in six months. 11.9% of respondents do not shop online via smartphone. 41 respondents (9.7%) shop online via smartphone only a few times a year.

Most of the respondents (61.1%) feel safe when shopping online. 60.6% of respondents are influenced by organic content provided by search results (e.g., Google) when shopping online. 56.1%, (236 respondents) are influenced by paid search content when shopping online. Most of the respondents (57.9%) are influenced by organic content on social networks when shopping online. Similarly, 56.2% of respondents are influenced by paid content on social networks when shopping online.

Most of the respondents (73.1%) are influenced by reviews and recommendations of family and friends when shopping online. Almost half of the respondents (49.4%) are influenced by the opinion of influencers, or celebrities they follow on social media when shopping online. Slightly more than half of the respondents (55.5%) are influenced by the newsletters they subscribed to when shopping online. The majority (69.1%) of respondents use price comparison engines (e.g., Heureka) when shopping online.

The hypothesis established hereunder assumed the existence of statistically significant associations between the frequency of shopping online using a smartphone and feeling safe when shopping online. This association was confirmed.

Efficiency of businesses` digital transformation for sustainable development

Jarmila Horváthová[1], and *Martina* Mokrišová[1,*]

[1] University of Prešov in Prešov, Faculty of Management and Business, Konštantínova 16, 080 01 Prešov, Slovakia

Abstract

Research background: Currently, the process of digital transformation in businesses is very important and often discussed. It decreases probability of businesses` bankruptcy and increases their sustainability on the market, which was also confirmed by the ongoing COVID-19 pandemic. An important goal is to speed up the digitalization processes taking place in businesses. It is very important to use already established digitalization elements more efficiently.

Purpose of the article: The aim of the paper was to evaluate the efficiency of the introduction of enterprises' digitalization elements in EU countries for the period 2019-2020.

Methods: To assess the efficiency of digital transformation selected business-oriented Digital Intensity Index (DII) indicators are applied. As part of the research, Malmquist Index (MI) based on the DEA (Data Envelopment Analysis) approach is used. The results of this model make it possible to assess how the change in technical efficiency and technological change contribute to the change in efficiency of the digital transformation in businesses within EU countries. Heat map is applied to graphically illustrate these results.

Findings & Value added: The contribution of the paper is the finding that dynamic evaluation brings new results in measuring the efficiency of businesses` digital transformation compared to static one. The finding is also the fact that leaders in the field of efficiency of digital transformation achieve 100% implementation of individual elements of digitalization, and therefore there is no need to evaluate their efficiency.

Keywords: business; digital transformation; efficiency; Malmquist index; sustainable development

1 Introduction

The process of digitalization is essential to ensure economic growth of EU countries. This path is particularly important for businesses in individual countries, as the economic growth of these businesses and their sustainability is a prerequisite for the growth of the country's economy. Digitalization also represents „a powerful mechanism for enhancing the sustainable competitiveness of economies worldwide" (Petkovski et al. 2022, p. 79). „Because of its transformational power, digitalization is discussed as an enabler of environmentally sustainable development" (Isensee et al. 2020, p. 2).

With the introduction of new digital technologies, the traditional ways of doing business have changed fundamentally. „Firms can stay competitive using the benefits of digital technologies, such as the internet of Things, social computing, Cloud computing, cyber-physical systems, big data and analytics, wireless networks, artificial intelligence, robotics, simulation, etc. The spread of the coronavirus disease in 2019 (COVID-19) all over the world has created a better understanding of the importance of organizations` ability to keep up with digital innovations" (Coskun-Setirek, Tanrikulu 2021, p. 1)

Within the EU, some countries have picked up these trends earlier and are leaders in the digitalization of their processes, whether at the level of the country, businesses or people. On the other hand, there are countries that lag behind for many reasons and still have considerable room to improve in the given area and to gradually introduce individual elements of the digitalization process.

Therefore, our research was focused on the level of introduction of individual digitalization services of businesses within the EU countries, since the sustainability of businesses is a prerequisite for the sustainability of the country's economy. Six key elements of enterprises` digitalization were implemented. Their use was evaluated by expressing the percentage of companies that apply them. Dynamic DEA and the Malmquist index (MI) were applied to evaluate the efficiency of the introduction of selected digitalization elements. The MI application can be considered a contribution in the given field of research, since with the use of this index it is possible to assess not only the static situation in the area of the introduction of digitalization services, but also to evaluate the efficiency of their introduction, in relation to the GDP and employment of the countries. The results of this research complement the DII index, which measures the percentage of businesses with introduced digital tools, by measuring the efficiency of their implementation.

Based on the above-mentioned the aim of the paper was to evaluate the efficiency of the introduction of enterprises' digitalization elements in EU countries for the period 2019-2020.

The remainder of the paper is structured as follows: Section 'Literature review' defines digitalization, briefly describes Digital economy and society index (DESI) and DII and lists the applications of various methods in the measurement of the efficiency of digital transformation. Section 'Data and methodology' specifies the source of the data and describes MI used to assess the efficiency of the introduction of enterprises' digitalization elements in EU countries. Section 'Results and discussion' offers the results of the change in efficiency over time calculated with the use of MI and compares its results with the outcomes of DII index. Section 'Conclusion' offers conclusions, limitations and future research.

2 Literature review

Digital transformation is „the modern mainstream of social and economic development promising significant digital dividends to citizens and businesses worldwide" (Dobrolyubova 2021). The introduction of quality digital infrastructure is crucial for almost every branch of the modern and innovative economy and society (Stankovic et al. 2021).

Digital competitiveness is a part of the overall concept of competitiveness. It represents „a multidimensional structure that encompasses various factors of the process of digital transformation through the ability of learning and application of new technologies, technology factors that enable digital transformation, and digital readiness factors that assess the preparedness of an economy and citizens to assume digital transformation" (Stankovic et al. 2021, p. 117).

Digitalization can be defined from different perspectives, it depends on whether we take into account the point of view of society, businesses or individuals. „Digitalization has been identified as one of the major trends changing society and business. It causes changes for companies due to the adoption of digital technologies in the organization or in the operation environment" (Parviainen et al. 2017, p. 63). Brennen and Kreiss (2016, p. 1) define digitalization as „the way many domains of social life are restructured around digital communication and media infrastructures ". Schallmo and Williams (2018, p. 6) define digitalization as „fundamental changes made to business operations and business models based on newly acquired knowledge gained via value-added digitization initiatives".

In line with the focus of the research, Gartner's (2015) more businesses-oriented definition of digitalization should be mentioned: „Digitalization is the use of digital technologies to change a business model and provide new revenue and value-producing opportunities; it is the process of moving to a digital business."

In order to measure progress in the development of the digitalization process, the Digital Economy and Society index (DESI) was developed and introduced in the European Union. DESI addresses the four interconnected principal policy areas of 2030 Digital Compass. These are Human capital, Connectivity, Integration of digital technology and Digital public services. These dimensions are of equal importance; therefore, they have equal weights (European Commission 2022). Among these policy areas, Connectivity and Integration of digital technology are the most important in relation to businesses. Olczyk (2022) in his research also found out that Connectivity has the largest impact on digital transformation in EU countries.

The level of digitalization in businesses is measured by the DII. It is a composite indicator derived from a survey on the use of ICT and e-commerce in businesses. A company's DII score (0-12) is determined by the number of selected digital technologies, which it uses. The higher the score, the higher the digital intensity of the enterprise. The composition of the DII varies between surveyed years depending on the questions included in the survey, so comparability over time may be limited (European Commission 2021a, European Commission 2021b).

Several authors have investigated the efficiency of the digitalization process using different methods, some of them are presented in the following text.

Petrovic et al. (2022) measured the efficiency of the use of information and communication technologies in businesses in order to assess the intensity and success of their digitalization process. Research sample consisted of businesses in the Republic of Serbia. To analyze the efficiency of digital business transformation the data envelopment analysis was applied, while for the robustness analysis of values of average efficiency they used bootstrapping method. They revealed that the process of digital business transformation in the Republic of Serbia is relatively efficient. The efficiency of e-commerce in businesses in most years was over 80%, on the other hand the use of software packages was insufficient. Kao et al. (2022) also applied Data Envelopment Analysis to investigate efficiency in implementing a digital transformation in Taiwanese firms. The study resulted in defining the inputs and outputs for the evaluation of performance of digital transformation of businesses. Authors also proposed performance evaluation approach which can help businesses to minimize risks associated with digital transformation.

Do et al. (2021) studied the impact of digital transformation on performance of Vietnamese commercial banks. They applied the GMM system (SGMM) of Blundell and Bond. To test he robustness of the estimated model they performed Bayesian analysis. The results of the research revealed that digital transformation has a positive influence on the performance of Vietnamese commercial banks.

Kalogiannidis et al. (2022) studied the effect of the digitalization on the performance of circular economy. Research sample consisted of 200 investors and entrepreneurs from Kozani in Greece. They applied regression analysis, while the dependent variable was a circular economy. The results of the regression analysis revealed positive relationship between digital practices and performance of a circular economy. Thai et al. (2022) also examined the impact of digital transformation on performance of businesses with the use of multiple regression model. Research sample consisted of Chinese firms. The results revealed that digital transformation enhances businesses` performance. Added value of the research was finding that businesses that have implemented digital transformation have lower costs, better operating efficiency and better innovation success, which means better performance.

3 Data and methodology

Indicators representing the digital transformation of EU companies, from the field of ICT usage in Enterprises, were selected as input data for fulfilling the aim of the paper and for assessing the efficiency of the digital transformation of enterprises and its impact on GDP and the unemployment rate. Indicators from the fields of E-commerce, Connections to the internet, Websites and use of social media, E-business and ICT security were chosen. The following inputs were used: E-commerce sales, Use of computers and the internet by employees, Type of connections to the internet, Websites and functionalities, Use of mobile connections to the internet, Cloud computing services.

GDP per capita and unemployment rate were used as outputs. The data of the EU-27 member states as well as the EU average were collected for the period 2019-2020. Descriptive statistics for selected indicators of the digital transformation of enterprises are presented in table 1.

Table 1. Descriptive statistics of selected indicators of businesses` digitalization

Variable	Descriptive statistics				
	Valid N	Median	Minimum	Maximum	Std. Dev.
E-commerce sales	27	18	8.0	38.0	7.9
Use of computers and the internet by employees	27	53	34.0	83.0	12.4
Type of connections to the internet	27	94	81.0	100.0	4.9
Websites and functionalities	27	76	46.0	96.0	12.5
Use of mobile connections to the internet	27	76	53.0	97.0	11.2
Cloud computing services	27	33	11.0	75.0	17.4

Source: Eurostat (2022)

The median of the share of E-commerce sales represents 18% of total sales. This share can be considered low. The median is slightly higher in the area of Use of computers and the internet by employees, in which 53% of participants use computers and the internet. Broadband Internet connection is used by up to 93% of employees. Websites and their functions are used by 76% of businesses, and the same % of businesses use a mobile Internet connection. Cloud computing services are used on average by only 33% of companies in the EU. Especially in this area of services, it is necessary to develop activities towards improving their use.

To assess the efficiency of the introduction of enterprises' digitalization elements in EU countries over-time, Malmquist index was applied. This index „measures the Total Factor Productivity (TFP) change between two data points by calculating the ratio of the distances of each data point relative to a common technology" (Casu et al. 2004, p. 2525). The index is based on the use of distance functions, which allow to describe production technology with multiple inputs and outputs without the need to specify the objectives of the company's behavior. It is possible to define both input and output distance functions (Fandel, 2002).

Several methods can be used to estimate distance functions, which are the starting point for calculating TFP. Linear programming is most often used, especially the Data Envelopment Analysis (DEA) method proposed by Färe, Grosskopf, Norris and Zhang in 1994 (Fandel, 2002). The use of DEA models to calculate TFP is related to the assumption that homogeneous data are available over several periods. Calculating the change in efficiency requires solving four linear programming problems, assuming the use of technology with constant returns to scale (Fandel, 2002).

Suppose that each $DMU_j(j = 1,2, \dots, n)$ uses a vector of inputs $x_j^t = \left(x_{1j}^t, \dots, x_{mj}^t\right)$ to produce vector of outputs $y_j^t = \left(y_{1j}^t, \dots, y_{mj}^t\right)$ at each period of time $t, t = 1, \dots, T$. Efficiency of DMU_0 can change or the frontier can shift or both changes may occur in the same time. The Malmquist Productivity Index is than defined as follows (1) (Zhu, 2014):

$$MI_o = \left[\frac{\theta_o^t(x_o^t, y_o^t)}{\theta_o^t(x_o^{t+1}, y_o^{t+1})} \frac{\theta_o^{t+1}(x_o^t, y_o^t)}{\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})} \right]^{\frac{1}{2}} \qquad (1)$$

where MI_0 measures the change in productivity between the periods t and $t + 1$. $\theta_o^t(x_o^t, y_o^t)$ is calculated by comparing x_o^t to the EPF (Empirical Production Frontier) at time t with the use of input oriented CRS DEA model, while $x_o^t = (x_{1o}^t, \dots \dots \dots x_{mo}^t)$ and $y_o^t = (y_{1o}^t, \dots \dots \dots y_{so}^t)$ are the input and output vectors of DMU_0 among others. Similarly $\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})$ is calculated by comparing x_o^{t+1} to the EPF at time t+1, $\theta_o^{t+1}(x_o^t, y_o^t)$ by comparing x_o^t to the EPF at time $t + 1$; and $\theta_o^t(x_o^{t+1}, y_o^{t+1})$ is calculated by comparing x_o^{t+1} to the EPF at time t applying input-oriented CRS DEA model.

This model is also available in its modified form (2) (Zhu, 2014):

$$MI_o = \frac{\theta_o^t(x_o^t, y_o^t)}{\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})} \times \left[\frac{\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})}{\theta_o^t(x_o^{t+1}, y_o^{t+1})} \frac{\theta_o^{t+1}(x_o^t, y_o^t)}{\theta_o^t(x_o^t, y_o^t)} \right]^{\frac{1}{2}} \qquad (2)$$

According to Fandel (2002) the term (3) represents the change in technical efficiency, it is the efficiency known according to Farrell (1957). The change in efficiency is equivalent to the ratio of Farrell's efficiency at time t and at time $t + 1$ (technical efficiency change between periods t and $t + 1$). Usually, this term expresses the improvement, deterioration or stability of technical efficiency.

$$\frac{\theta_o^t(x_o^t, y_o^t)}{\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})} \qquad (3)$$

The term (4) represents the frontier shift (FS) in the EPF between periods t and $t + 1$ (Zhu, 2014).

$$\left[\frac{\theta_o^{t+1}(x_o^{t+1}, y_o^{t+1})}{\theta_o^t(x_o^{t+1}, y_o^{t+1})} \frac{\theta_o^{t+1}(x_o^t, y_o^t)}{\theta_o^t(x_o^t, y_o^t)} \right]^{\frac{1}{2}} \qquad (4)$$

The values of indicators can be interpreted as follows:
$TECH > 1$ the efficiency of the DMS improved, it approached production possibility frontier, the decisions taken were correct,

$TECH = 1$ the efficiency of the DMS did not change,
$TECH < 1$ the efficiency of the DMS declined; the decisions taken were incorrect.

TECH informs about a change in technical efficiency but does not inform about a shift in production possibility frontier as a result of technological change. This is reported by frontier shift as follows:

4 Results and discussion

The resulting MI index for the years 2019-2020 is presented in Table 2. From this table it is obvious that the change in the efficiency of the use of digitalization elements in companies over time in relation to the change in GDP and unemployment is above the value of 1 in most EU countries, which can be evaluated positively. Slovenia, Lithuania and Croatia achieve an MI value below 1. The digitalization process in these countries appears to be inefficient from the point of view of applied inputs and outputs. Bulgaria achieved the highest efficiency value, followed by Latvia, Poland, Luxembourg, Romania, and Hungary. Slovakia ranked 13th with a value of 1.04. Based on the results, it can be concluded that Bulgaria achieved a significant result compared to other EU countries, including in the area of Efficiency Change, where it reached a value of 1. This means that the efficiency of using the already established elements of enterprise digitalization does not change and is stable.

Table 2. Results of the Malmquist index

DMU No.	DMUs	Malmquist Index	Efficiency Change	Frontier Shift
1	Belgium	1.02053	0.97854	1.04291
2	Bulgaria	1.20524	1.00000	1.20524
3	Czechia	1.03444	0.98212	1.05327
4	Denmark	1.00829	0.97815	1.03082
5	Germany	1.05252	0.99694	1.05575
6	Estonia	1.02621	0.96412	1.06440
7	Ireland	1.00327	0.99333	1.01001
8	Greece	1.07202	0.96676	1.10888
9	Spain	1.02094	0.97402	1.04817
10	France	1.02046	0.96868	1.05345
11	Croatia	0.98715	0.94342	1.04635
12	Italy	1.03389	0.96336	1.07321
13	Cyprus	1.04210	0.96765	1.07694
14	Latvia	1.11587	1.03357	1.07963
15	Lithuania	0.98042	0.92888	1.05549
16	Luxembourg	1.09327	1.00000	1.09327
17	Hungary	1.07574	1.00000	1.07574
18	Malta	1.02505	0.96914	1.05769
19	Netherlands	1.05520	0.97472	1.08257
20	Austria	1.04301	0.99786	1.04525
21	Poland	1.10820	0.96570	1.14755
22	Portugal	1.05470	0.97765	1.07881
23	Romania	1.07917	1.00000	1.07917
24	Slovenia	0.97342	0.91687	1.06168
25	Slovakia	1.04207	0.97671	1.06692
26	Finland	1.03218	0.98948	1.04316
27	Sweden	1.01798	0.98360	1.03495

Source: authors (2022)

In the area of technological change in the process of businesses` digitalization, Bulgaria even ranked 1st with a value of 1.21. The most efficient country in the area of Efficiency change is Latvia, which reached a value of 1.03 in the given area, which indicates an increase

in the efficiency of the use of already established digitalization elements in enterprises. Romania, Luxembourg and Hungary achieved a value of 1 in the field of Efficiency change, which means that they use the already established elements as efficiently as Bulgaria. In the case of other EU countries, there was a decrease in efficiency. The results in the field of technological change can be evaluated highly positive, as every EU country reached a value above 1. This is due to the introduction of new digitalization elements or an increase in the number of companies that switch their activities to use these elements.

A more detailed analysis of the results shows that Bulgaria has achieved an increase in the number of businesses using selected digitalization elements (E-commerce sales, Use of computers and the internet by employees, Type of connections to the internet, Websites and functionalities, Use of mobile connections to the internet, Cloud computing services). In the case of Slovakia, there was an increase in all areas of digitalization process evaluation as well. In the case of e-commerce, the number of companies that introduced this element increased the most in Denmark and Croatia. The number of businesses in the indicator "Use of computers and the internet by employees" increased in all 27 EU countries. The most significant increase in the number of businesses was recorded for the Cloud computing services indicator, especially in Denmark, Estonia, Italy, Malta, Finland and Sweden. This area is currently a priority for EU countries in introducing digitalization services. These services include the use of services such as e-mail, which is used by 76% of EU companies, storage of files by 67% of companies and office software by up to 57% of EU companies. Other services used include: hosting the enterprise's databases, which is used by 47% of enterprises, financial and accounting software – 45%, computing power for enterprises own software – 24%, CRM (Customer Relationship Management) software applications – 27%.

Apart from the assessment of efficiency over time and the impact on GDP growth and employment, Denmark is the leader in the introducing digitalization elements. In the field of e-commerce, Ireland and Denmark are the leaders, in the field of Use of computers and the internet by employees, Sweden is the best country. Type of connections to the internet is 100% applied in companies in Denmark and 99% in companies in Finland. Websites and functionalities are 94% - 96% established in Finland and Denmark. Finland and Sweden are leaders in the introduction of the indicator: "Use of mobile connections to the internet". The last analyzed indicator was Cloud computing services, while the best achieved values of the introduction of this indicator were achieved by Finland, which was able to increase the percentage of enterprises in which cloud computing technologies are introduced by 10% within 2 years. Based on the above-mentioned, it can be concluded that especially Denmark should be excluded from the evaluation of the efficiency of enterprises, as it reaches 100% in some indicators, as a result of which no further improvements can be expected.

The DII results show that Finland, Denmark and Belgium have a higher share of companies with a high degree of digitalization, while the lagging countries have a lower share of companies with a high degree of digitalization. For example, in Bulgaria and Romania (both 66%), Greece (60%), Latvia (57%) and Hungary (53%), most businesses show a very low DII, indicating a small investment in digital technologies. These countries are expected to increase the value of the index by 2030, so that 90% of small and medium businesses reach a higher level of DII. The results of the DII are monitored for several years, and it should be noted that they cannot be compared over the years, as the DII is processed according to the questions included in the survey, and these are different in individual years and are scored.

Based on the above, it would be appropriate to implement a method of measuring the efficiency of the digitalization process in companies within the EU, which would assess the digitalization process more precisely. It would also be appropriate to maintain the same parameters for measuring the digitalization level to ensure comparability over time. For this reason, the DEA and MI method appears to be a suitable alternative. The results of the MI model show that according to selected indicators of digitalization of EU businesses Slovakia

ranked 13th. Results of efficiency change and frontier shift are displayed graphically with the use of heat map (see figure 1).
Figure 1. Heat map.

Source: authors (2022)

4 Conclusion

It is necessary to look at the results of the research from a static as well as a dynamic point of view. The static view records the state of the digitalization process at a given period, for example a year, while the dynamic one measures the efficiency of the transformation over the years, in relation to selected output parameters (GDP, unemployment rate, production, turnover, etc.). From a static point of view, countries like Denmark, Finland, Sweden and Belgium have achieved almost 100% enterprise adoption in most applications of digital tools, and further increase in the number of enterprises is not possible. These countries can be considered leaders, so in the case of these countries, the dynamic measurement of efficiency is irrelevant. It follows that when analyzing the digitalization process of enterprises, it is important to evaluate not only the quantity of introduced digitalization elements, but also the efficiency of their implementation and use, also in relation to GDP growth and employment growth in the country. This more or less confirms the findings of Inel (2019) and Yalcin (2021).

Slovakia should focus on its weaknesses. It lags behind Denmark in the area of e-commerce sales by 11%. At the same time, it should be noted that even Denmark, despite being a leader in the field of digitalization of companies, achieves coverage in this area at the level of 38% of companies. In the tool "Use of computers and the internet by employees" Slovakia lags behind Finland, which is the leader in the given area by 40%. Websites and functionalities is a category in which Finland is the leader and Slovakia lags behind by 20% of companies. Finland and Sweden achieve the highest % in the area of Use of mobile connections to the internet, while Slovakia lags behind by 20% of the companies that use this digitalization element. Probably the biggest losses are recorded in Slovakia in the field of

Cloud Computing Services. These services are implemented in 26% of enterprises in Slovakia, while Finland is the leader in this area with 75% of enterprises in which these services are applied.

Based on the above, it can be concluded that Finland, Sweden and Denmark are the leaders, which achieve a high % coverage of enterprises in which digitalization elements are introduced. Therefore, when evaluating the efficiency of the implementation of digitalization tools, less developed countries that were in the analyzed period in the phase of their introduction, appear in the leading positions.

Abstract

Research background: The accelerating global development is reflected in the changing qualification needs of the labor market. If higher education is to fulfill its role well, it must be able to respond to these changes. It is necessary to align competences, areas of interest with education and training and the demands of the global labor market so that they correspond to the individual needs of the university student.

Purpose of the article: The aim of this paper is to identify emerging trends in application of virtual reality (VR) technologies in career counseling / guidance at universities as one of the forms of education of university students with regard to their successful employability in the global labor market.

Methods: The bibliographical analysis is carried out primarily on the platform of Web of Science, or others eventually. This is organically combined with the analysis of the current technological solutions in the field of career counselling by means of VR.

Findings & Value added: Current findings reveal following trends in using career counseling using virtual reality: job exploration or immersive job tasting, job simulation with varying degree of interactivity, career and personality diagnostics, job shadowing and virtual company immersions, soft-skills and job interview simulations. The use of virtual reality in the career counseling process will prepare university students for the complex challenges of the global age.

Keywords: *Virtual reality, career counselling / guidance, university education, global trends*

1 Introduction

Industry 4.0, the coronavirus pandemic, the globalized world and the serious social and economic consequences associated with them have accelerated and accentuated fundamental changes in the global labor market. We have entered a world where the virtual world, digital literacy, flexibility in the labor market and the ability to proactively approach a career are no longer just buzzwords, but an absolute necessity for future employment on the global labor market. (Hirschi, 2018). The coronavirus pandemic and the serious social and economic consequences associated with it have accelerated and accentuated fundamental changes in the labor market. Youth unemployment is currently a problem facing many regions and countries. The unemployment rate over the past decade has been historically high, exposing college students to the long-term negative effects of unemployment (Musset and Kurekova 2018). Career counseling could help in this situation. Virtual reality has spurred concrete changes in the field of career counseling. The use of technologies based on virtual reality fully covers the first two subsets of career counseling (career education and career information) and psychometric testing and the development of competences in the field of job search are also considered as part of the activities.

The aim of the article is to identify trends in the use of virtual reality in the career counseling process in the form of bibliometric analysis based on the Web of Science Core Collection platform, which allows identifying current scientific and professional trends in academic publications.

2 Theoretical Background

Virtual reality (VR), as well as the so-called augmented reality (originally augmented reality; AR) they are a technological achievement of recent years. Although for many people this term primarily means a connection with computer games and entertainment activities, it is gradually finding use in the field of human resources in companies and career counseling in secondary schools and universities (Alhalabi, 2016). Virtual reality (VR) is the use of computer technology to create a simulated environment. VR can be defined as a newer technology system in which virtual objects are added to the real world in real time during the user experience (Azuma, et al., 2001). Virtual reality can be defined generally: "The use of computer technology to create an interactive three-dimensional world in which objects create a sense of spatial presence; virtual environment and virtual world are synonyms for virtual reality." (Lopreiato et al. 2016, in Kardong-Edgren et al., 2019). Definitions of VR vary, but they emphasize three common features of VR systems according to three aspects:

- The degree of immersiveness represents the intensity of the feeling of immersion in a computer-generated environment.
- Interactivity is a measure of the intensity and complexity of interaction with the world within virtual reality.
- Information corresponds to the quantity and quality of information that the user shares with the virtual space as part of interactions in the virtual space (Parveu and Adda 2018).

There are a wide variety of applications for virtual reality, from training and certification programs to career exploration and client assessment tools. These are some of the areas where virtual reality could start to be used for career development. According to (Target Connect 2019, in Senichev), the use of virtual reality in career counseling appears in the areas of:

- virtual practice,
- simulation of specific jobs,
- virtual career fairs and

- provision of career consultations in VR.

Obviously, this calculation will not be final and it is possible to expect the emergence of new platforms and their combinations. Students often find choosing the right career to be exhausting as there are so many opportunities but also many uncertainties. They usually choose several occupations of interest that match their abilities and interests to analyze through research. Fortunately, virtual reality makes it much easier to better understand your preferred occupation and explore the occupations of the future (Chircu, 2014). Career counseling offers a supportive space that helps job seekers navigate the complex and ever-changing global world of work and enables them to find their own solutions to various challenges (Whiston and Rose, 2015). Career counseling is defined by the OECD as: "a system of counseling services. Its aim is to help individuals of all ages make decisions about

- education,
- vocational training,
- employment and career choices at any stage of their lives." (WGCG OECD 2019).

NCDA understands KP as a form of working with a client based on the establishment of a professional counseling relationship and the potential to assist clients with career and personal development issues beyond those covered in career planning" (NCDA, 2015). Career counseling is based on the three paradigms of

- professional counseling,
- career education and
- life design (Savickas, 2012).

Traditional approaches can respond to challenges arising from changes in the world of work, therefore using new approaches in career counseling becomes a necessity (Maree, 2015). Through the use of VR, job seekers can experience first-hand the pros and cons of different occupations by seeing, hearing and feeling what they are really like. At a job interview, they have to face many challenges such as

- introversion,
- insecurity,
- lack of technical or
- social skills.

During this process, the teacher, career counselor can observe and gain valuable information about the individual that traditional pen and paper style assessments may not indicate, e.g. how he reacts to high-stress situations. Therefore, quality preparation can be decisive for success on the labor market. By combining various technologies, such as

- virtual reality,
- tracking the direction of gaze during an interview,
- recognizing emotions,
- analyzing verbal aspects,

it can provide the candidate with valuable experience and feedback (Stanica et al. 2017).

3 Methodology

The literature is increasingly recognizing the potential benefits of VR as a tool supporting a unique process of competency development and career adjustment. As part of the analysis of current professional and scientific trends, a bibliometric analysis based on publications in the Web of Science (WoS) was used.

The basic unit of bibliometric research are scientific journals, as they have a long-term important position in scientific communication, further clearly defined publishing standards and a high-quality assessment system (peer review), which ensures the originality of the published results of scientific research (Glänzel, 2003). The basic measures of bibliometric

research for the analysis of scientific production are the number of publications and the number of citations.

Bibliographic analysis within the platform reveals scientifically and professionally established trends. The analysis was carried out in logical steps, first a narrower search according to the occurrence of terms in the title, then according to the occurrence of terms in the text. In the search, terms defining the exact wording were used: "Virtual reality", "Career guidance", "Career counselling", "Career advisory", which are used in the sense of career / career advice. Additional search parameters: search within the WoS Core Collection database, unlimited languages, unlimited time range, unlimited other parameters.

3.1 The bibliographical analysis

For a more comprehensive view of the content of the article, we present terms with aspects of career counseling (career - counseling / guidance / advisory /planning) within the WoS platform (abbreviation CC):
-    1 227 (term in the document title), 3 604 (expression in the text of the document);
-    and terms based on the term "virtual reality", (abbreviation VR):
-    25 683 (VR or virtual reality in the title of the document),
-    69 294 (VR or virtual reality in the text of the document).

The analysis based on the occurrence of the word in the text is less accurate, since the text can discuss other topics as well. On the other hand, this approach to analysis can provide a more comprehensive overview of research topics and trends in a given area. The following tables present the output of the citation analysis.

Table 1. Bibliographic analysis: VR and career counseling in the title of the article

Year	Publication	Number of citations	Topic
2021	Demareva, V., Petrova, I., & Zhukova, M. (2022). **Digital Career Guidance Technologies: Using Virtual Reality**. Annual Review of Cybertherapy and Telemedicine 2022, 131.	0	Technologies in VR for CC
2022	Estrada, J. G., & Prasolova-Førland, E. (2021, March). **Developing VR content for digital career guidance in the context of the pandemic**. In 2021 IEEE Conference on Virtual Reality and 3D User Interfaces Abstracts and Workshops (VRW) (pp. 38-43). IEEE.	0	Technologies in VR for CC

Source: WoS, Citation Report, 8/2022

The first article discusses technologies using VR in career counseling, and the second article discusses a similar topic, but with an emphasis on the context of the pandemic situation. Not a single publication has so far been cited in a publication indexed on Web of Science, which is not surprising given the recent publication date.

Table 2. Bibliographic analysis: VR and career counseling in the text of the article

Year	Publication	Number of citations	Topic
2005	Kim, G. J. (2005). **A SWOT analysis of the field of virtual reality rehabilitation and therapy**. Presence, 14(2), 119-146.	478	Vision, medicine
2018	Hardcastle, T., & Wood, A. (2018). **The utility of virtual reality surgical simulation in the undergraduate otorhinolaryngology curriculum.** The Journal of Laryngology & Otology, 132(12), 1072-1076.	11	Medicine
2020	Prokhorov, O. V., Lisovichenko, V. O., Mazorchuk, M. S., & Kuzminska, O. H. (2020). **Developing a 3D quest game for career guidance to estimate students' digital competences**. In CEUR Workshop Proceedings (pp. 312-327).	5	Testing career competencies in VR
2020	Rölfing, J. D., Jensen, R. D., & Paltved, C. (2020). **HipSim—hip fracture surgery simulation utilizing the Learning Curve–Cumulative Summation test (LC-CUSUM)**. Acta orthopaedica, 91(6), 669-674.	3	Medicine
2012	Chen, C. T. (2012). **Development and Evaluation of Senior High School Courses on Emerging Technology: A Case Study of a Course on Virtual Reality.** Turkish Online Journal of Educational Technology-TOJET, 11(1), 46-59.	3	Technique in VR for CC
2021	Lin, A. P., Trappey, C. V., Luan, C. C., Trappey, A. J., & Tu, K. L. (2021). **A Test Platform for Managing School Stress Using a Virtual Reality Group Chatbot Counseling System**. Applied Sciences, 11(19), 9071.	1	Technique in VR for CC
2019	Fominykh, M., & Prasolova-Førland, E. (2019, March). **Immersive Job Taste: a Concept of Demonstrating Workplaces with Virtual Reality**. In 2019 IEEE Conference on Virtual Reality and 3D User Interfaces (VR) (pp. 1600-1605). IEEE.	1	Technique in VR for CC
2019	Prasolova-Førland, E., Fominykh, M., & Ekelund, O. I. (2019, March). **Empowering young job seekers with virtual reality**. In 2019 IEEE Conference on Virtual Reality and 3D User Interfaces (VR) (pp. 295-302). IEEE.	1	Technique in VR for CC
2022	Zhu, L. (2022). **Work Emotion Intervention and Guidance Training Method for Enterprise Employees Based on Virtual Reality**. Occupational Therapy International, 2022.	0	Tréning
2021	Demareva, V., Petrova, I., & Zhukova, M. (2022). **Digital Career Guidance Technologies: Using Virtual Reality**. Annual Review of Cybertherapy and Telemedicine 2022, 131.	0	Technique in VR for CC
2022	Estrada, J. G., & Prasolova-Førland, E. (2021, March). **Developing VR content for digital career guidance in the context of the pandemic**. In 2021 IEEE Conference on Virtual Reality and 3D User Interfaces Abstracts and Workshops (VRW) (pp. 38-43). IEEE.	0	Technique in VR for CC

Source: WoS, Citation Report, 8/2022

The highest number of citations (478 in total) goes to a visionary article from 2005, which talks about the perspectives of using VR in the field of therapy. Two articles are devoted to the use of VR in the training of surgical skills. Five publications are focused on the use of VR in career counseling. One publication is devoted to the testing of work competencies on a game platform in virtual reality and the application of emotion work competency training intended for employees.

From the citation analyses, it is clear that the number of publications indexed in Web of Science on the given topics is surprisingly low, as is the number of citations. This clearly points to the fact that these are really new and unexplored areas.

4 Discussion and Conclusion

Career counseling is not immune to VR experiences. There are a wide variety of applications for virtual reality, from training and certification programs to career exploration and client assessment tools. These are some of the areas where virtual reality is beginning to be used to develop careers in the global job market through virtual experiences for individuals. Career exploration and development takes

- time,
- resources and
- effort.

And there are many stakeholders in this process, from students and employers to university support services. New technologies open more doors to information and experience, but the real innovation will come when these tools connect with students in ways that help them make career decisions (Greenidge, 2013). John Sumser, founder of HRExaminer, said that turning job interview and workplace simulations into VR experiences could help in recruiting large numbers of employees. A key benefit of using VR is that students are immersed in the experience and not distracted, notes Dan Eckert, executive director of PwC's AI and Emerging Technologies Applied Research Lab (Lawton, 2021). In the presented article, the basic terms in the field of career counseling and virtual reality are defined and a bibliometric analysis was carried out based on the Web of Science Core Collection platform, which made it possible to identify current scientific and professional trends in academic publications. From the bibliographic research within science and research, it emerged that the topic "application of virtual reality in career counseling" represents a very young, little-established and practically just starting scientific discipline. Based on the analysis, we have identified the following trends, directions and visions of the use of VR in career counseling, which are likely to appear in the near future:

- virtual tour (exploration) of the workplace with varying degrees of interactivity,
- simulation of the workplace in a virtual space,
- practice of a job interview in virtual reality,
- job shadowing and participation in sample company events in real time,
- use of VR in the field of HR with the direct possibility of use in career counseling (diagnosis and assessment centers, training for specific job positions in VR).

The findings can be used as a starting point for further research on VR as a career guidance tool. The use of virtual reality in the career counseling process will prepare university students for the complex challenges of the global era. VR also shows strong potential for career guidance. Businesses and universities will have to overcome several challenges on the way to widespread adoption of VR in career guidance.

A global view of the bibliometric analysis of creative accounting and earnings management

Lenka Hrosova[1,*]

[1]University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: Looking back on history, it is possible to identify certain circumstances that could have stimulated the emergence of creative accounting, such as the emergence of individual states in the world, or the need for economic entities to establish a good position in the market. Over time, the terms creative accounting and earnings management began to appear more and more in the global business environment. Several keywords were created, with the help of which it was possible to identify them more deeply and also to monitor the growing importance of the given issue in a global aspect.

Purpose of the article: The purpose of this article is to analyze keywords accompanying the issue of creative accounting and earnings management in the global business environment for the period 1989-2021 through bibliometric analysis.

Methods: For this article, the scientific database Web of Science will be used as a database, containing a large number of professional and scientific publications related to the addressed issue in the period 1989-2021. Based on the acquisition of input data from this database, a bibliometric analysis of keywords will then be performed using the VOSviewer program.

Findings & Value added: With the growing number of publications, the number of keywords also increased, which signals a growing interest in the issue of creative accounting and earnings management. The global economic crisis resulted in a significant increase in publications and keywords in countries around the world since 2008. After 2008, the number of publications as well as keywords continues to grow significantly, so we can say that the issue of creative accounting and earnings management is attracting more and more scientific attention. researchers in the field of finance.

Keywords: *bibliometric analysis, creative accounting, earnings management*

JEL Classification: *M41; F60*

1 Introduction

Accounting is the primary source of information based on which individual entities make all financial decisions. This is precisely the reason why the importance of accounting in the financial field is growing. Accounting provides important information not only to entrepreneurs performing their business activities but also to other entities whose decisions are based on accounting. Since accounting represents the main source providing very important information, it must provide all interested entities with a faithful and true picture of the accounting reality. According to the current Slovak legislation, the Accounting Act defines a faithful and true presentation of accounting as follows: "the presentation of accounting in an accounting unit is faithful if the content of the items in the financial statements corresponds to the facts and is by the established accounting principles and accounting methods and the presentation of accounting in the accounting unit is true if the principles and methods of accounting leading to the achievement of a true picture of the facts in the given financial statements are used within it." Based on the definition of true and fair presentation of the accounting facts, there should be no distortion of the accounting information, and there should also be no manipulation of accounting unit statements. However, the growing importance of accounting also brings with it certain risks. Accounting units in the business environment are aware that their evaluation takes place based on the achieved financial results, which are recorded in the accounting statements, which the accounting units must publish if they are entered in the Commercial Register. This may be the motive to "embellish" the actual financial results and thus resort to the use of creative accounting, through which accounting units can in a certain way modify the economic result either by reducing it or transferring a lower amount of funds to the state or by increasing it to attract more attention from investors. As part of the development of the global economy, creative accounting is written about in the professional literature in a positive but also a negative sense. Some of the authors think that creative accounting provides savings accounting units from bankruptcy. Other authors consider creative accounting illegal and violating accounting principles. Salustro and Leburn (2000) think that for companies in a period of crisis, the crisis is a test for these companies, in which the cash flows of the company are affected and the risks arising from the performance of business activities increase, which motivates managers to use creative practices. accounting (Salustro and Leburn, 2000 in Balaciu et al. 2009). Watts and Zimmerman (1978) are representatives of positive accounting theory. Their research studies became the basis for several empirical studies investigating the relationship between the choice of accounting practices and political costs. Brown and Steele (1999) compiled a portfolio of a total of twelve accounting techniques, in which they additionally combined a selection of accounting procedures tied to decisions made by business managers. According to Kovanicova (2005), creative accounting represents "the process of manipulating accounting data to transform financial accounting statements from the form in which they should be properly kept within the framework of a faithful and true representation of the accounting reality to the form that would be desired by those who are responsible for keeping accounting data and implementing economic transactions to report the required financial performance and cash flows of the given accounting unit." Griffiths (1995) points to the fact that companies report such results that are not a true and fair image of their transactions, but rather adjust them according to the desired goals. The economic results reported by companies are based on appropriate, adjusted, or changed data. These practices used in reporting business operations or performance are considered creative accounting. Mulford and Comiskey (2002) define creative accounting as "steps taken to game financial statements, including aggressive selection and application of accounting principles, either within or outside generally accepted accounting principles, and fraudulent accounting reporting." These authors in the context of

the definition of creative accounting, explain fraudulent accounting reporting as the deliberate misrepresentation or omission of certain values and attachments in financial statements made to mislead the users of these financial statements and perceived as fraudulent from an administrative, civil or criminal point of view. Baloun (2004) refers to creative accounting with the term tendonitis. This term is understood in the professional literature as a criminal act of distorting accounting data on the state of management and capital, which in the case of capital markets represents a serious problem indicating the error rate of the system in the reporting of assets and profit and the misuse of the information in business relations. Jameson (1987) explains creative accounting as an accounting sphere in which, as part of the accoing process, there is an assessment and resolution of conflicts regarding the approaches to the presentation of the company's financial results associated with financial cases and their transactions, which, from the author's point of view, creates an opportunity for the modification of financial data and deceptive presentation of the company.

2 Methods

For the bibliometric analysis, the Web of Science scientific database was used as a database, which contains a large number of scientific articles by domestic and foreign authors dealing with the issue of creative accounting and earnings management. For this article, four areas were analyzed, namely economics, management, corporate finance, and business, respectively entrepreneurship in the period 1989-2021, while the minimum number of publications per author was set at the level of 5 publications. The VOSviewer program was used to analyze the total number of articles, with the help of which it was determined in which countries the issue of creative accounting is mostly addressed. Using this program, a total of 65 countries with the largest number of articles related to the addressed issue were identified. Individual countries were divided into nine clusters according to similarity, with each cluster marked with a different color. Within the professional and scientific publications found in the Web of Science database, keywords in the field of creative accounting were further detected through bibliometric analysis. The development of keywords for the given issue was analyzed in the period 1989-2021, while the total analyzed period was divided into ten years. The total number of analyzed keywords reached 8306.

3 Results and Discussions

Using a bibliometric analysis, we found out in which countries the issue of creative accounting and earnings management is mostly addressed, as well as which of the authors deal with the given issue the most in a global environment. As a database, we used the Web of Science scientific database, which contains countless scientific articles by domestic and foreign authors on the given issue. We focused on four areas, which are economics, management, corporate finance, and trade, respectively entrepreneurship in the period 1989 - 2021. In total, we identified 65 countries with the largest number of articles on the given issue, while individual countries were divided into nine clusters according to similarities.
Figure 1. Bibliometric analysis of Creative accounting from a global perspective

Source: Own processing using the VOSviewer program

The first cluster includes nineteen countries, including Bahrain (11 articles), Egypt (53 articles), England (430 articles), France (138 articles), Jordan (48 articles), Kuwait (23 articles), Lebanon (21 articles), Libya (12 articles), Malaysia (194 articles), Oman (13 articles), Pakistan (50 articles), Qatar (14 articles), Saudi Arabia (75 articles), Scotland (72 articles), Tunisia (100 articles), United Arab Emirates (46 articles), Vietnam (59 articles), Wales (34 articles), Yemen (34 articles). The second cluster includes eight countries including Cyprus (14 articles), Ghana (14 articles), Greece (72 articles), Kenya (8 articles), Nigeria (28 articles), South Korea (200 articles), Switzerland (36 articles), Turkey (33 articles). The third cluster includes a total of eight countries, including Bangladesh (11 articles), Brazil (114 articles), Chile (22 articles), Japan (53 articles), Mexico (9 articles), Portugal (51 articles), Russia (9 articles), Spain (238 articles). The fourth cluster contains a total of seven countries, namely Austria (23 articles), Denmark (14 articles), Germany (160 articles), India (99 articles), Indonesia (95 articles), Kosovo (5 articles), and Slovenia (10 articles). The fifth cluster includes a total of seven countries, namely Australia (468 articles), Belgium (53 articles), Finland (51 articles), Italy (154 articles), the Netherlands (101 articles), Norway (35 articles), and Sweden (26 articles). The sixth cluster consists of seven countries, which include the Czech Republic (23 articles), Iran (51 articles), New Zealand (142 articles), Poland (37 articles), Romania (41 articles), the Slovak Republic (34 articles), South Africa (19 articles). The seventh cluster includes six countries. These are Canada (353 articles), Israel (31 articles), China (931 articles), Singapore (105 articles), Taiwan (315 articles), USA (2373 articles). The eighth cluster consists of two countries such as Ireland (25 articles) and Monaco (8 articles). The ninth cluster is made up of one country, namely Thailand (25 articles).

The total number of foreign and domestic publications generated by the scientific database Web of Science is 5890 articles. The following graph shows the number of studies in the studied period 1989 - 2021.
Figure 2. Number of publications in the period 1989-2021

Source: Own processing using the VOSviewer program

The growing number of publications captured through the graph signals a growing interest in the issue of creative accounting and earnings management. The global economic crisis resulted in a significant increase in publications in the countries the world since 2008. Since 2008, the number of publications continues to grow significantly, so we can say that the issue of creative accounting and earnings management is attracting more and more attention from scientific researchers in the field of finance. Among the countless studies related to the issue of creative accounting and earnings management, we present some of them. Aygun (2013) considers creative accounting as an essential tool for informing third parties about an accounting unit. He explained the possible strategies and their effectiveness in practicing creative techniques in the company. Dias et al. (2016) examined auditors' opinions on the issue of creative accounting and earnings management from an ethical point of view. Nica and Ionita (2016) describe the practices of creative accounting and its impact on the quality and reliability of financial data. Stangova and Vighova (2016) characterized creative accounting as a common phenomenon in the recording of financial results in companies. They also pointed out methods by which it is possible to avoid the practice of creative accounting in accounting units with an impact on public finances. Dugar and Gujarathi (2018) analyzed the company Toshiba Corporation to identify the use of possible procedures in adjusting the reported profit in the period 2008-2014. The results of the study showed that this company adjusted its profits by almost two billion US dollars in the analyzed period of 2008-2014. Remenaric et al. (2018) presented in their publication the main incentives for the manipulation of financial data, the most used creative techniques, and also the steps necessary to eliminate the use of creative accounting procedures. Falcon, Sanchez, and Vizcaino (2019) analyzed the incentives through which accounting information is modified to report economic results that do not correspond to reality. Another of the authors, Renu and Sharma (2020), focused their attention on creativity in the field of human resources. Through their study, they tried to identify the scope of creative accounting in the company as well as the influence of auditors representing the key human factor. Saleh, Jawabreh, and Abu-Eker (2021) focused on identifying the motives leading to the use of creative accounting in hotels operating in Jordan and their impact on financial statements. Olojede and Erin (2021) investigated the impact of corporate governance mechanisms on the use of creative accounting in the country of Nigeria. They included a sample of seventy companies in the analysis, while their study pointed to the elimination of the use of creative accounting through corporate governance mechanisms, which is significantly influenced by regulation. Studies

by other authors deal with the questions in which countries' earnings management occurs the most, to what extent, how this phenomenon can be measured and whether company managers are also involved in its practice. Based on these questions, it is clear that the issue of earnings management is very topical in the financial sphere and more and more authors are interested in it. Linhares, da Costa, and Beiruth (2018) verified whether there is a relationship between the quality of accounting data assessed based on earnings management and the efficiency of investments made through companies operating in Brazil listed on the stock exchange in the period 1996-2012. The results of the study demonstrated the impact of earnings management on the level of investments. Based on the results of the given study, the authors think that a higher scope of earnings management is associated with a higher probability of deviation from the ideal investment level. Valaskova, Kliestik, and Kovacova (2019) detected earnings management through the Jones model and the Modified Jones model in Slovak companies operating in the automotive industry. The results of their study demonstrated a higher ability of the original Jones model in detecting earnings management in Slovak companies compared to the Modified Jones model.

Through bibliometric analysis, they further detected keywords in the field of creative accounting and earnings management in the period 1989-2021. The total number of keywords that were analyzed is 8306. The following images show the development of keywords related to the issue of creative accounting and earnings management in individual periods, divided by year.

Figure 3. Keywords in the period 1989 - 1999

Source: Own processing using the VOSviewer program

Due to the low number of existing publications in the observed period 1989 - 1999 focused on the issue of creative accounting and earnings management, we also identified a low number of keywords. Accrual, earnings management, and discretionary accrual were among the most important keywords related to the presented issue in the given period.

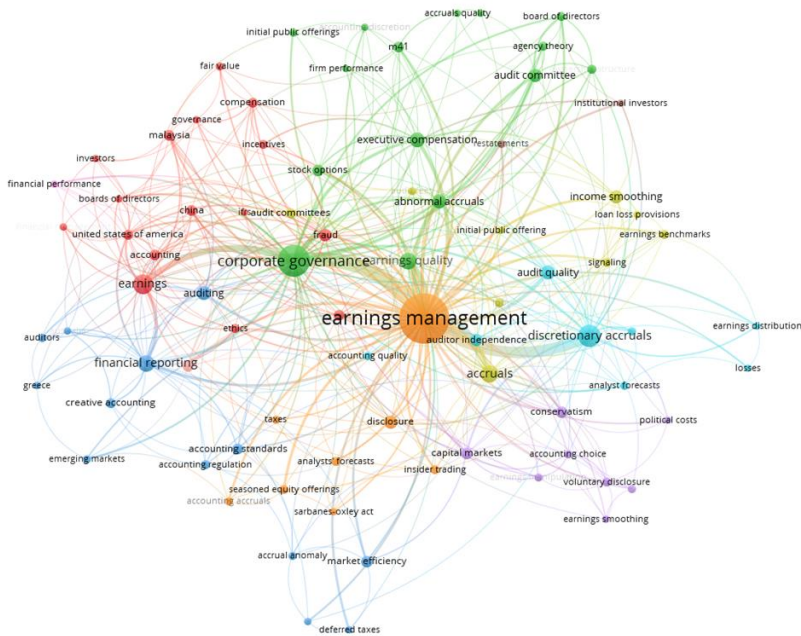
The number of publications from 2000 to 2010 has increased significantly compared to the previous period 1989 - 1999. As a result, the number of keywords has also increased. In the following picture, we can see their mutual connection, while in the years 2000 - 2010, the motives for the creation of creative accounting and earnings management were already gaining attention. Through a long-term period, it is possible to compare significant changes in the development of the issue of creative accounting and earnings management, as well as changes in the perception of the solved issue before and after the onset of the global economic crisis.


Figure 4. Keywords in the period 2000 - 2010

Figure 5. Keywords in the period 2011 - 2021

Source: Own processing using the VOSviewer program

In the period 2011 - 2021, we can observe a more complex connection of keywords compared to the two previously analyzed periods 1989 - 1999 and 2000 - 2010, as a significantly larger number of professional and scientific publications in the world were created in this period. In addition to basic concepts such as creative accounting and earnings management, techniques or motives for their creation, attention is also paid to the division of earnings management according to its forms, profit models used to detect and identify the presence of earnings management, the countries in which the presented issue is mostly solved or entities that can practice creative accounting and earnings management in the financial sphere in world countries and many other keywords.

Conclusion

Based on the results of the bibliometric analysis, it can be concluded that the issue of creative accounting is a global phenomenon that is becoming more and more popular not only in the V4 countries, but also in other countries of the world, and which it is necessary to pay due attention since the manipulations of financial data and profit occurred not only because of the global economic crisis, but it is also occurring now. When we look at the current economic situation due to the Covid-19 pandemic, we can say that its effects on world economies are negative. Partial or complete restriction of business operations results in a fundamental reduction of revenues, profit, and cash flow, or the generation of permanent costs. Not to mention the credit risk, as a result of which there may be a fundamental reduction in the receivables turnover time or the receivables will not be paid in full. All these negatives can lead to a decrease in the market capitalization of companies.

Abstract

Research background: Digitalisation was one of the key drivers of economic growth during the 5th cycle of Kondratieff Waves. Moreover, digitalisation is still an important factor enabling future changes during the 6th cycle. While the private sector is often, a leading one in digitalisation, the public sector should also keep pace with it. Our paper deals with digitalisation as a potential approach to reducing tax evasion.

Purpose of the article: We assume that tax evasion is to some extent affected by the degree of digitalisation in the public sector. The usage of digital technologies in the public sector can have several consequences for the effectiveness of tax administration, tax audits as well as the willingness of taxpayers to pay a tax. The paper aims to identify the potential relationship between the degree of digitalisation in public administration and the estimated level of tax evasion in EU countries.

Methods: We analysed secondary panel data for 27 EU countries in the period 2008-2021. The analysis is based on Pearson correlation, Granger causality and cointegration tests. This approach allows us to identify the significance and the directionality of potential effects between tax evasion and the usage of digital services.

Findings & Value added: We found a significant relationship between both factors and effects in both ways. However, the effect arising from tax evasion on digital public services seems to be even more evident. Based on the results we can make certain conclusions and recommendations for tax policy and public policy supporting digitalisation.

Keywords: *tax evasion, digitalisation, digital transformation, public services, e-government.*

1 Introduction

The process of gradual digital transformation has been present in the private as well as the public sector for a rather long time. Despite this fact, the process is far from completed and become even more inevitable during the Covid-19 pandemic accompanied by social distancing. The public sector often lagged behind the business in several aspects of digitalisation. Improvements in digitalisation and e-government can have several other benefits except for the increase in the quality of public services and expected decrease in administration and compliance costs. The induced reduction of tax evasion can be seen as one of them. This paper is focused on examining the relationship between digitalisation in the public sector and the estimated level of tax evasion. There are various reasons why we can expect a such relationship to exist. Firstly, digitalisation usually improves the efficiency of the process of tax audits and increases the possibility of detecting tax evasion. From the perspective of taxpayers, there are fewer possibilities for undetected free-riding. Online communication with the government also eliminates personal contact between officials and taxpayers to a minimum which reduces the possibility of bribery or any other corrupt practices. Furthermore, online information and consultations improve the awareness of the tax law and potential fines among taxpayers. All these aspects can lead to a decrease in tax evasion in countries with higher intensity of digitalisation in the public sector.

   The main aim of this research is to identify the potential relationship between the degree of digitalisation (the use of digital technologies to change a business model and provide new revenue and value-producing opportunities) in public administration and the estimated level of tax evasion in EU countries. We used available secondary macro-level panel data to examine trends and the potential relationship between both problems in the short-run as well as in the long run. To fulfil the aim, we apply correlation analysis, panel Granger causality test as well as panel cointegration tests. In the next section, we briefly summarize the theoretical assumptions related to the examined problem and provide some examples of previous research in this field. The methodology and data used in the analysis are described in the third section of the paper. The fourth section shows the most important results of our analysis with economic interpretation. Finally, we make conclusions and policy implications in the last section of the paper.

2 Literature review

Today, society and digital technologies are very closely connected. They dynamically transform the world, simplify many activities and bring more accessible and transparent information to people. Their influence on many social sciences is undeniable. We also notice the impact of digitalisation in the area of tax systems. Thanks to digitalisation, the administrative burden can be reduced, cooperation between tax authorities can be improved, tax systems can be managed more efficiently, and the amount of tax evasion can also be eliminated. By tax evasion we mean economic activity that is unregistered, illegal and dishonest, but otherwise would contribute to increasing the gross national product (Schneider and Enste, 2000; Orviská and Hudson, 2003; Orviská, 2005; Kiabel and Nwokah, 2009). When defining tax evasion, we also encounter the concept of tax avoidance, which represents a reduction of tax liability that does not violate the law, but on the other hand, uses the possibilities that the law allows. Tax avoidance occurs when using the imperfections and ambiguities of legislation in the area of tax policy, but also through the use of legal adjustments in the form of a preferential tax regime (Fuest and Riedel, 2009; Prebble and Prebble, 2010; Alm, 2012). Medina and Schneider (2018) advise one of the reasons that lead to hiding economic activities mainly regulatory ones, which mainly include avoiding

government bureaucracy and the absence of more effective methods of communication with institutions - digitalisation.

Under digitalisation, we can imagine the process of converting information into digital form. According to Veber et al. (2018) this is a process that leads to the capture of data, its preservation, analysis and evaluation. However, it should be kept in mind that the digitalisation process does not take place evenly, mainly due to the existence of territorial differences, the level of literacy of the population and, last but not least, the availability of the Internet network and many other factors.

According to Alm (2021), rapidly changing technologies probably influence the development of tax evasion in a positive direction from the point of view of the governments of individual countries. Technological changes ensure a faster and smoother flow of information between tax subjects and public administration bodies and their subsequent analysis. They also facilitate the process of taking measures, or policies to eliminate tax evasion. The ability of governments to monitor and subsequently analyze transactions about which they have information makes it possible to increase the revenues of state budgets. The authors Kitsios et al. (2020) claim that digitalisation represents an opportunity for fiscal policy because it depends on information about economic actors, respectively. tax subjects and can improve tax compliance by increasing the efficiency and quality of information in business transactions. However, digital technologies are available not only to public administration bodies, but also to tax entities, which, thanks to their use, can circumvent legal regulations, thereby increasing tax evasion. In their publication, the authors Remeikiene et al. (2017) define the digital shadow economy and identify its characteristic features and channels.

There are currently several studies that examine the relationship between e-Government initiatives and tax evasion. E-Government is an indicator that measures the efficiency of public administration and also measures the achieved level of digitalisation in the field of public services. The level of electronic public administration increases in direct proportion to the increasing number of digital public administration services, operations and transactions that take place in the digital space. In connection with tax evasion, we encounter the opinion that tax evasion has a decreasing tendency in countries where the public administration and tax system are efficient from the point of view of tax collection and subsequent allocation of income (Sidani et al., 2014). Alm and Liu (2018) offer a different perspective on the issue, who claim that corruption is an important determinant of tax evasion. Thanks to digitalisation, the level of corruption can be reduced, which ultimately has an impact on reducing tax evasion. A study by Uyar et al. (2021), in contrast to previous studies, provides empirical evidence that the direction of the governments of individual countries and their ability to respond to changes plays a significant role in the elimination of tax evasion. The long-term orientation of governments towards the provision of effective digital services and prompt response to technological changes are decisive factors for achieving the digital transformation of the public sector, which in turn causes a decrease in tax evasion.

3 Methodology and data

The paper aims to identify the potential relationship between the degree of digitalisation in public administration and the estimated level of tax evasion in EU countries. To do so we analysed secondary macro level panel data. Tax evasion has been proxied by the estimates of the shadow economy in EU countries provided by Schneider (2021). To analyse the activities in e-Government and their development, we used data for the Digital Public Administration Factsheets, compiled by the European Commission annually. It evaluates the activities of EU states in this field. The report is divided into main 7 parts, and its overall goal is to support best practices in the field of digital service provision and their sharing

among EU countries. It focuses on the public administration and infrastructure of e-Government and the services provided for citizens and entrepreneurs. Data for each indicator is available in the Eurostat database. Based on the theoretical background and our main aim we have chosen the following Digital Public Administration Indicators:

- interaction with public administration bodies,
- obtaining information from the websites of public administration bodies,
- downloading official forms,
- sending completed forms to public administration bodies.

All variables used in the analysis are described in Table 1. Tax evasion was indirectly captured by the estimates of the shadow economy as a percentage of GDP. The other four variables are used in the form of the percentage of individuals who used mentioned feature of e-government.

Table 1. Description of variables used in the analysis

Variable	Description	Source
Tax evasion	Schneider (2021) estimation of the shadow economy (in % of off. GDP) – as a proxy for tax evasion	Schneider (2021) Development of the Shadow Economy of 36 OECD Countries over 2003 - 2021
Online interaction	Percentage of individuals using the internet for interacting with public authorities (%)	Eurostat (2022) Digital Public Administration factsheet - 2022
Downloading forms	Percentage of individuals using the internet for downloading official forms from public authorities (%)	
Online filling	Percentage of individuals using the internet for sending filled forms to public authorities (%)	
Obtaining information	Percentage of individuals using the internet for obtaining information from public authorities (%)	

Source: Authors based on the data from Eurostat and Schneider (2021).

Our dataset consists of panel data. Thus all variables include a cross-sectional (country) dimension as well as a time dimension. The panel was balanced and it includes the data for EU27 countries in the period 2008 – 2021. Together 378 observations have been used in the analysis. Basic descriptive statistics of each variable are shown in Table 2.

In the first stage of the analysis, we graphically display the data and use Pearson correlation coefficients to identify potential linear relationships between each pair of variables. Next, all variables have been tested for weak stationary by using the Levin et al. (2002), Im et al. (2003) tests as well as the Fisher ADF and PP tests defined by Choi (2001) and Maddala and Wu (1999). Results are shown in the analysis. Variables that appear to be stationary at levels have been used directly in the further analysis. On the other hand, variables become stationary at their differences.

Table 2. Basic descriptive statistics of variables used in the analysis

	Obs.	Mean	Median	Std. Dev	Min.	Max.
Tax evasion	378	18.73	19.1	14.35	5	77
Online interaction	378	58.25	60	19.55	60	94
Downloading forms	378	36.33	37	14.35	5	77
Online filling	378	34.76	31	19.70	3	83

Obtaining information	378	51.60	53.0	18.80	8	92

Source: Authors.

To fulfil the main aim of the paper we tested the short-run causalities in the Granger sense by panel Granger causality tests. We also assume that potential relationships should appear to be evident not only in the short-run but also in the long run. To further test the long-run relationship we apply panel cointegration analysis.

Firstly, we need to demonstrate the same level of integration for the variables entering the cointegration analysis. This has been tested by the panel unit root tested mentioned in the text.

Only two non-stationary variables with the same level of integration are those capturing tax evasion and the percentage of individuals using an online filling. Thus we tested for the existence of cointegration of these two variables by panel cointegration tests developed by Pedroni (2004) which are widely used in the empirical literature. They are testing the null hypothesis of no cointegration between selected variables. Pedroni uses seven different statistics. Four of them are panel cointegration statistics based on the within the approach and three of them are group-mean panel cointegration statistics which are based on the between approach.

4 Results

Firstly, we examined the tendencies in the extent of tax evasion proxied by the share of the shadow economy on GDP. To see the trend during the selected period in the EU we take into account the average values for all 27 EU countries. The development of tax evasion can be seen in Figure 1.
Figure 1. The development of mean estimates of tax evasion in EU countries during the period 2008-2021.

Source: Authors based on the Schneider (2021) estimates.

During the period 2008-2019, the trend appears to be significantly decreasing from more than 20% to less than 17%. However, there is an increase during the year 2020.

Similarly, we also show the trend in the usage of online interaction with the government and obtaining information online (Figure 2 and Figure 3). The situation is similar in both indicators. Despite some short-term slump in the year 2013, there is an increasing trend during the selected period. Hence, in general, we can conclude that the usage of selected e-government tools is increasing while tax evasion is mostly decreasing in the EU as a whole.
Figure 2 and 3. The development of mean percentage of individuals using online interaction with government and obtaining information online.

Source: Authors based on date from Digital Public Administration factsheet – 2022.

All five variables have been further put into correlation analysis. The results can be seen in Table 3. The table shows the Pearson correlation coefficients for variables without incorporating any potential lags or leads. The results indicate that there is a negative linear correlation between tax evasion and all four variables capturing the usage of e-government tools. The correlation coefficients are in the range between -0.33 and -0.4 which indicates a rather less intensive correlation. On the other hand, the correlation between all four variables of e-government is positive and significantly more intensive. These results are mostly in line with our theoretical expectations. The strongest positive correlation is between the percentage of individuals using the online filling and those using online interaction with the government.

Table 3. Pearson correlation coefficients between examined variables

	Tax evasion	Online interaction	Downloading forms	Online filling	Obtaining information
Tax evasion	1	-0.399	-0.402	-0.354	-0.333
Online interaction	-0.399	1	0.846	0.850	0.952
Downloading forms	-0.402	0.846	1	0.762	0.802
Online filling	-0.354	0.850	0.762	1	0.782
Obtaining information	-0.333	0.952	0.802	0.782	1

Source: Authors.

To proceed further in the analysis, we need to test the stationarity of all variables used in the analysis to avoid any potential spurious correlation. For this purpose, we used panel unit-root tests (as described in the methodology). The results are shown in Table 4. As it can be seen two out of five variables are not stationary (weak stationarity) at levels. Hence we further used their first difference when are all stationary. Variables capturing online interaction, downloading forms and obtaining information are all stationary even at their levels so we can use them in the analysis in this form.

Table 4. Panel unit root tests of all variables used in the models

	Levin, Lin & Chu	Im, Pesaran and Shin W-stat	ADF - Fisher Chi-square	PP - Fisher Chi-square
Tax evasion	-0.82	2.51	26.86	20.44

Δ Tax evasion	-14.7***	-10.52***	211.01***	262.01***

Downloading forms	-2.99***	-1.37*	85.04***	75.34**
Online filling	1.36	3.74	45.27	48.41
Δ Online filling	-13.67***	-9.98***	192.74***	215.95***
Obtaining information	-10.68***	-5.34***	131.52***	143.03***

Source: Authors.

After the unit-root test, we can proceed to Granger causality between selected pairs of variables. The results are summarized in Table 5. Granger causality is using lags to capture potential delay and identify the direction of potential effect. We decided to use from one to three years lag. Our results appear to vary especially with different pairs of variables but significantly less with different settings of lags. There seems to be no statistically significant effect either from online interaction to tax evasion as well as in the opposite direction. On the other hand, we found a positive effect in the Granger sense acting in the direction of tax evasion to downloading online forms and online filling. This is significant for all three lags. Hence, it seems that the extent of tax evasion and the shadow economy in the country is affecting the way and intensity of how taxpayers and other individuals are using e-government tools serving for sending information about themselves to the government. The usage of pre-peppered online forms and online fillings can be affected by the trust in the government, general attitude to digital technology as well as the intention of potentially illegal behaviour. Hence, we assume that in the middle of higher tax evasion, the willingness to provide information online to the government could be lower. On the other hand, we also found the effect arising of informing online to the share of tax evasion. Getting information from online government sources can increase the awareness of public services, public administration as well as tax laws and potential penalties for violating them. On one hand, this can lead to more information on correct tax returns, tax payments and the extent of public services provided from collected taxes which can positively increase willingness to pay a tax. On the other hand, more information about the fines and penalties for tax evasion can lead to a lower incidence of tax crime.

Table 5. Results of Pairwise Panel Granger causality tests

	F-statistic		
Number of lags:	1	2	3
H0: Online interaction does not Granger cause ΔTax evasion	0.46	0.75	0.47
H0: Δ Tax evasion does not Granger cause Online interaction	2.39	1.06	0.54

Observations	324	297	270

Source: Authors own computation.

Note: */**/*** means significance at the 10%/5%/1% level of significance

The Granger causality tests allow us to identify potential effects with certain lags in the short run. However, the effects between tax evasion and the usage of e-government tools can be even more evident in the long run. Therefore, we also test for a potential long-run relationship. In this case, we examine the relationship between tax evasion and usage of online fillings because both variables have the same order of integration which is a necessary condition for the cointegration test. We use the set of Pedroni panel cointegration tests

described in more detail in the methodology section. The results of all tests are summarised in Table 6.

Table 6. Results of Pedroni panel cointegration tests

Cointegration: Tax evasion, Online filling			
Pedroni tests (Engle-Granger based) – individual intercept & trend, lag length selection based on SBC	Panel v-Statistic (within dimension)	4.67***	3.48***
	Panel rho-Statistic (within dimension)	-2.42***	-1.85**
	Panel PP-Statistic (within dimension)	-2.52***	-1.98**
	Panel ADF-Statistic (within dimension)	-3.03***	-2.97***
	Group rho-Statistic (between dimensions)	0.82	
	Group PP-Statistic (between dimensions)	-1.43*	
	Group ADF-Statistic (between dimensions)	-2.54***	

Source: Author´s own computation.

Note: */**/*** means significance at the 10%/ 5%/ 1% levels.

As it can be seen a vast majority of the test suggest the rejection of the null hypotheses at a 5% level of significance. Hence we found that there is a long-run relationship between the level of tax evasion and usage of online fillings. Based on this methodology solely we are not able to directly identify the intensity and direction of the long-run effect. However, we can still conclude that both problems are not connected only in the short-run but there is also a long-run relationship between them.

Despite our best effort to use the best possible methodology to achieve our main aim, there are also several limitations related to our approach. First of all, due to the chosen methods, we are not able to estimate any direct causal effect and apply any control variables. This approach allows us only to examine the relationship between the pairs of variables. To further examine the intensity and significance of potential causal effects, it would be more appropriate to use regression analysis based on fixed effects, random effects regressions, or the GMM approach. Moreover, we are not able to capture potential differences among EU countries. This can be solved for example by using separate correlation analysis for every state or at least incorporating the dummy variables into regression analysis. However, we believe that our research provides unique and interesting results which can be further examined in detail.

5 Conclusions and policy implications

The paper was focused on the examination of the relationship between tax evasion and digitalisation in public services. Based on the results of correlations analysis, Granger causality tests and cointegration tests we found empirical evidence for this relationship in the short-run as well as in the long run perspectives. Both problems appear to be connected at different levels. The short-run effect is evident in the direction from tax evasion to the share of individuals filling online forms and downloading prepared forms. This means that the current level of tax evasion is affecting the willingness of individuals to share information online with the government in the future. This means that to achieve more intensive usage of these e-government tools it is firstly necessary to lower the level of tax evasion in the country. Trust in government, social responsibility and ethical norms can be seen as a factor affecting both of these problems. On the other hand, more frequent obtaining information online from the government is related to a lower level of tax evasion. The increase in awareness of tax laws and potential fines among taxpayers can deter tax evasion. More information about public services as well as social and individual benefits owing to public expenditures can positively influence the willingness to pay taxes for some individuals. This means that more

online information and consultation can potentially lead to the reduction of tax evasion. We also identify a significant long-run relationship between filling online forms for the government and tax evasion. Our results suggest that certain type of digitalisation of online services is positively related to a reduction of tax evasion in the country. Hence, it is likely that the cost related to digitalisation in the public sector can be to some extent partly paid by the increased tax collection.

The impact of internal marketing on human resource management effectiveness in the Vietnamese public sectors

Thang Nam Huynh[1]*, Hoa Doan Xuan* Trieu [1,*]*, Phuong Van* Nguyen[1], and *Tung Van* Nguyen[1]

[1] Center For Public Administration, International University, Vietnam National University–HCMC

Abstract

Research background: In response to the increasing demands of the public for the quality of public services, state administrative agencies recognize the necessity for cultural changes inside the organization. In public administration, maintaining and promoting the organization's basic values, purpose, and mission in the face of social trends is a crucial responsibility.

Purpose of the article: The purpose of this research is to comprehend how internal marketing influences human resource efficiency and employee performance in public administration when organizational and cultural innovation is prevalent. Based on the suitable, scientifically sound, and trustworthy findings of the research on the factors impacting the efficacy of human resources management in public services, it is then possible to provide options for improving the performance of the government unit.

Methods: This quantitative study employs the PLS-SEM methodology to analyze a dataset of 202 samples gathered from 300 public sector officials in Vietnam to determine the relations between internal marketing, leadership style, employee performance, and human resource effectiveness.

Findings & Value added: Empirical study verifies the partial mediating role of employee performance in relationships of charismatic leadership style and internal marketing to human resource management effectiveness. The findings suggest that to ensure the effectiveness of the organizational structure, organizational system, and staff retraining, public organizations should prioritize the human element during the restructuring process. Leadership style contributes significantly to the ability to care more about employees, better assist them, and notably allocate work more effectively to fit employees' personalities and preferences, hence enhancing employee productivity and human resource efficiency.

1 Introduction

In response to changes in citizen demand and the quality of public services, the public administration acknowledges the need for organizational reform to fulfill civilian requirements. At the current time, internal marketing plays a significant part in the resource efficacy of the providers who make the pleasure of the public service for the citizen and contribute to the operation of the organization. Internal marketing is crucial to the success of an organization because it conveys necessary information and messages to the right people at the right time, with the main content being the vision, purpose, core values, and the objectives of developing, consolidating, and disseminating corporate culture. In the meanwhile, human resource management (HRM) is responsible for recruiting, applicant and staff data management, course organization and administration, etc. Human resource management is the act of hiring and managing people for public administration organizations, whereas internal marketing is responsible for disseminating information and engaging staff.

During the age of innovation, local governments in Vietnam have used internal marketing campaigns to achieve human resources effectiveness under government policies and legislation that promote the delivery of successful public services. However, simultaneously keeping internal staff and attracting externally skilled recruits is a difficult challenge. This challenge illustrates the importance of leadership in managing internal market operations and sustaining the performance of followers. Therefore, the need to comprehend how internal marketing influences the efficacy of human resources and employee performance in Vietnam's public administration when organizational and cultural innovation is a top concern.

Human resource management (HRM) duties are the effective activities of hiring, developing, and motivating able personnel. Meanwhile, internal marketing and the organization's internal customers may have an impact on human resource performance in public administration (Huang, 2020). Prior study is less likely to investigate the function of leaders in constructing their followers and mostly disregards the leadership trait of enhancing internal marketing and employee performance outcomes. In the meantime, the significance of an employee's role inside a company focuses significantly on organizational performance (Hartline et al., 2000). Internal marketing and employee performance have a significant impact on the effectiveness of human resources in organizations and businesses, a phenomenon that has been extensively researched in several disciplines. However, the study on internal marketing and employee performance with the efficacy of human resources in public administration has not been well-received in public administration, particularly in Vietnam. Consequently, it is important to pay attention to these gaps due to their significance to employee performance and internal marketing efforts.

This research focuses on the ideas of internal marketing and the effectiveness of human resources at the local government level in Vietnam to remedy the gaps that have been identified. In the present phase of public sector reform and innovation, it is essential to acknowledge the importance of variables influencing the efficiency with which local governments use their human resources.

2 Conceptual frameworks

HRM policies have important short-term impacts in addition to long-term effects that contribute to sustainable development. In an analysis of the idea and definition of HRM, (Ewing & Caruana, 1999) suggest that HRM is a required and beneficial determinant of organizational performance. To be more precise, the programs that supervisors deliver to their followers have the potential to affect the workers' ability, competence, and dedication, as well as raise the degree to which the objectives of organizations and employees are aligned (Guest, 1992). The transition from human resource management theory to practice did not

occur naturally but was necessary in terms of both time and resources to effectively manage the sociopolitical, environmental, and constructional problems. As a result, to improve their organizational efficacy, businesses have focused their efforts on implementing the fundamental components of human resource effectiveness (Ruel et al., 2007).

2.1 Internal marketing and employee performance

Internal marketing is the activities and processes to keep all members of an organization up to date with the necessary information, whether it is the work on a project or the general direction of the organization. In many organizations, when employees understand the workplace environment, they are likely to comprehend communication (Huang, 2020). The framework of internal marketing was initially introduced as a marketing strategy to enhance external marketing performance (satisfaction and loyalty). The organization can motivate employees to perform a high capability and distribute extraordinary customer service since they transfer the services to the organizational external customers. Consequently, internal marketing drives organizational orientation (Vella et al., 2009).

The term "human resource initiatives" is used in the internal market to illustrate how practices of HRM that affect performance may be managed by focusing on the formulation of performance evaluations (Carlson et al., 2006). The conceptual model on the link between internal marketing and employee performance in terms of behavior reveals itself as the result of efforts made in the area of internal marketing from the point of view of human resources (Huang, 2020). Internal marketing examines the positions of employees, in contrast to human resource practices, which center on the workers from the organization's point of view (Ewing & Caruana, 1999).

Employees are seen as a vital precondition in internal marketing, which increases internal marketing performance and will strengthen employee performance, according to the internal marketing concept and multi-dimension identified proposed by (Y.-T. Huang & Rundle-Thiele, 2014). Management academics have identified employee motivation as one of the most important characteristics of a business, particularly concerning the performance of employees in their jobs (Oh et al., 2011). Communication inside the organizational hierarchy that is effective and efficient is connected with employee attitudes, and employee attitudes are what create the quality of internal service (To et al., 2015). Employees who encourage interactive marketing may be satisfied and inspired by a robust internal marketing program that offers a variety of options. The workflow of HRM gives priority to training and continues to prioritize exceptional workers even after evaluating employees who have worked experience-related qualities (Huang, 2020). Earlier research shows that there is a positive association between employee work attitude and performance and internal marketing practices. This finding lends credence to the idea that successful internal marketing is associated with favorable employee job performance and attitudes (Boswell et al., 2006). The fact that a qualitative study was conducted by (Huang, 2020) on evaluating all papers concerning internal marketing and internal customer also shows that there is a link between internal marketing and employee performance. According to the findings of the research on internal marketing, HRM practices, and employee work performance in organizations, there is a substantial correlation between internal marketing and employee work performance.

Previous researchers in a wide variety of sectors have provided evidence that supports the relationship between internal marketing and employee performance. Despite this, there is a clear deficiency in the research carried out by public institutions. As a result, a hypothesis on the relationship between internal marketing and the performance of public servants in public organizations is provided as follows in this study:

H1: Internal marketing impact positively on employee performance.

2.2 Internal marketing and HR effectiveness

The areas of internal, external, and interactive marketing all play an important part in HR management and application. However, the value of internal marketing to the efficacy of HR among internal employees is far larger (Ewing & Caruana, 1999). According to (Grönroos, 1981), the active and continuous effect of internal marketing on employee development and good performance in profitability in the business was cited as a significant factor. Internal marketing is also regarded to be part of the organizational strategy that includes human resource management and marketing to attract and retain high-caliber service professionals to provide the highest possible level of service quality while interacting with customers (Gummesson, 2000). In addition, internal marketing is the instrument that managers use to inspire, motivate, engage, and control their employees when they approach marketing and HRM to improve the quality of services they provide for their workforce (Joseph, 1996). (Barnes et al., 2004) provide evidence that suggests employees are more likely to be highly motivated and to contribute to the achievement of organizational visions, goals, and effectiveness when their managers and supervisors satisfy the demands of internal customers. (Barnes et al., 2004) also found that this was the case.

The view in psychological theory that HR professionals serve as internal customers may be most suitable if they get dedication and contributions from marketing and the human resource function (Lewis & Varey, 2000). The fact that internal marketing plays a part in the development and growth of human resource effectiveness is indicative of the close connection that exists between internal marketing and HRM. The positive results of internal marketing may be attributed to several characteristics of human resource management, including the accomplishment of duties by workers, their level of satisfaction with their work, the view that the tasks have been completed properly, and trust. As a result, the association is strengthened as a result of the execution of internal marketing activities and human resource management effectiveness and practices (Bansal et al., 2001).

According to the workers' point of view, the role of HR professionals is to care for them and the needs they have in the workplace; this is the primary emphasis of the idea of internal marketing (Ewing & Caruana, 1999). It has been established that the empirical results of the effect of internal marketing on employee happiness, service quality, and job performance are demonstrated (Tansuhaj et al., 1991). Therefore, the internal customers (workers) will fulfill the expectations of external customers (climates of the firm) with the utmost effort from the service of internal marketing. Scholars have supported the relationship between internal marketing and human resource effectiveness, particularly in the public sector, who argued that internal marketing in fulfilling the needs and demands of the internal customers is the essence of developing HRM and has an impact on the human resource effectiveness in the organization. These scholars argued that internal marketing has a relationship with human resource effectiveness because it fulfills the needs and demands of internal customers (Ewing & Caruana, 1999). This article, which is part of a comparable research topic, tests a hypothesis on the internal marketing and human resource effectiveness in the local government. The hypothesis is as follows:

H2: Internal marketing impact positively on human resource effectiveness.

2.3 Employee performance and HR effectiveness

The performance of the employees influences the outcomes, which are displayed in the form of service quality, customer satisfaction, brand loyalty, and customer value. At the same time, an individual's performance has an impact on the overall success of the organization, which can be seen in terms of the firm's efficacy and performance (Huang & Rundle-Thiele, 2014; Huang, 2020). Although human resource effectiveness is primarily responsible for defining

organizational objectives and effectiveness, employee performance is also an extremely important factor in determining how successful a company is. As a consequence of this, there may be an existing connection between the performance of employees and the HR effectiveness in the business. Regrettably, there is a dearth of research that investigates the nature of this connection. In light of the prior research, the following direct associations will be investigated in this study:

H3: Employee performance impact positively on HR effectiveness.

2.4 Charismatic leadership and employee performance and HR effectiveness

The leaders in charismatic leadership are those who command attentiveness to the working environment and the needs of workers, transmit a clear vision and perspective for the organization, and drive followers to grasp and comprehend the attitudes and actions of subordinates. Several studies have shown that leaders are the factors that have a greater influence on the mental state of workers. This influence may vary from low levels of argument and equivocation to high levels of inspiration, all of which help to progress and enhance performance (Wieseke et al., 2009). A message is an essential component of social contact, serving as the medium through which communication takes place (Fiske, 2010). Within the company, it is recommended that service marketers work to strengthen and maintain fluent manager-employee communication to maximize their performance to the organizational goal. This is because fluent communication between managers and employees helps to reduce the negative effects of misunderstandings while also ensuring that good services are effectively delivered (Wang et al., 2014).

The previous researcher has stressed the critical role that leadership plays in maintaining open lines of communication with employees to improve individual performance inside the organization (Wieseke et al., 2009). The leader of a charismatic organization is skilled in altering their followers' awareness of their job performance, motivating them to complete the specified ideas and objectives in the organization, and improving an intensive collective alignment among the workers (Conger, 1999). In addition, workers have a greater tendency to be drawn to and adopt a leader's vision when they are motivated. In this study, the functions of charismatic leadership, such as encouraging employees and decreasing conflict, as well as being able to define a transparent vision, are investigated to see how they affect the performance of employees and human resource effectiveness via the following hypothesizes:

H4: Charismatic leadership impact positively on employee performance.
H5: Charismatic leadership impact positively on HR effectiveness.

3 Methodology

Most of the measurement items used for this study have been adapted from previous research. Moreover, two journalists were invited and then agreed to participate in individual interviews and focus on clarifying the technical and appropriate terms in the context of research such as local government in Vietnam. The items for internal marketing and human resource effectiveness were adopted from (Ewing & Caruana, 1999). The charismatic leadership scales relied on the role of leadership in internal marketing adopted from (Wieseke et al., 2009). Lastly, employee performance scales were adapted from the prior study in the public sector of (Henttonen et al., 2016).

The observations are the public servants who have been working at the administrative offices, agencies, and departments in a local government in Vietnam. According to (Hair et al., 2014), the minimum number of samples necessary to do exploratory factor analysis (EFA) for research consisting of 18 observed variables is 100. The needed ratio of a sample size to

the number of observed variables is 1:5, hence with 18 observed variables, the survey sample size must be more than 100 samples.

4 Data analysis

4.1 Measuring model assessment

The measuring model evaluation was carried out to evaluate the reliability and validity of measurement scales. The measurement model satisfies all criteria, including the requirement of reliability as well as its convergent and discriminant validity (Hair et al., 2014).

Table 1. Convergent validity

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)
	> 0.6	> 0.7	> 0.7	> 0.5
Employee performance	0.875	0.878	0.915	0.728
HR Effectiveness	0.863	0.864	0.907	0.709
Internal marketing	0.915	0.915	0.936	0.746
Leadership	0.915	0.92	0.936	0.746

Table 2. Fornell-Larcker Criterion

	(1)	(2)	(3)	(4)
Employee performance (1)	0.853			
HR Effectiveness (2)	0.569	0.842		
Internal marketing (3)	0.534	0.54	0.864	
Leadership (4)	0.525	0.402	0.544	0.864

Table 3. Heterotrait-Monotrait Ratio (HTMT)

	(1)	(2)	(3)	(4)
Employee performance (1)				
HR Effectiveness (2)	0.653			
Internal marketing (3)	0.592	0.603		
Leadership (4)	0.582	0.449	0.59	

4.2 Path analysis
Figure 1. Structural model results

To get p-values for significant values, we analyze the structural model using bootstrapping using 4999 samples. As can be seen in Figure 1, four out of the five hypotheses are demonstrated to be acceptable when evaluated using p-values of 0.05, which is equivalent to a confidence level of 95%. The overall R-square of the research model is 0.402. Having regard to the outcomes, the implementation of internal marketing will foster employee performance (ß = 0.353, p <0.001) and human resource effectiveness (ß = 0.321, p <0.001) in the public organization. In other words, the results support these hypotheses that internal marketing has a positive relationship with employee performance and HR effectiveness which means H1 and H2 are supported. The findings accept H3 that employee performance has a positive influence on the HR effectiveness in the local government (ß = 0.384, p <0.001) meaning H4 is supported.

4.3 Discussion

The findings indicate that if an organization properly manages its internal marketing, the employee will function effectively and efficiently. These results demonstrate the link between internal marketing and employee performance. Moreover, the findings are consistent with those of (Huang & Rundle-Thiele, 2014), who describe the core notion of internal marketing as an increase in employee performance, given that the employee is the essential condition of the company and the internal customers of these businesses. Similar to Huang (2020), the findings provide evidence to demonstrate the existence of a strong link between internal marketing and employee perspectives, particularly employee performance. Prior study indicates a clear association between internal marketing and employee work performance in the organization. This study revealed that using internal marketing in public administration improves the organization's human resource effectiveness. When internal marketing by employers satisfies the desires of internal consumers, workers are more likely to be engaged in and achieve the organizational objectives and missions.

This study is consistent with recent studies which indicate that the performance of public agency personnel will boost the human resource effectiveness of the company. When workers accomplish a task effectively and efficiently, they anticipate receiving their human resource effectiveness rewards (such as their perks in public administration, remuneration, safety, and health care) first. The results provide significant evidence to support the previous study's conclusion that the performance of internal customers in businesses would grow steadily when internal marketing in HRM is effectively implemented (Huang, 2020).

Although there is a considerable association between charismatic leadership and employee performance, leadership is not significantly related to human resource effectiveness. To encourage and motivate people to offer their efforts to government agencies, leaders must enhance the remuneration based on the productivity of employees. Importantly, local government officials must also develop good communication skills regarding the organization's objective and vision. Empowerment is essential for organizational effectiveness, which necessitates charismatic work assignment decisions based on individual capabilities. In the innovation phase of boosting internal marketing, executives are responsible for altering employees' perspectives, catching up with the latest trends, and considering long-term advantages.

5 Conclusions

This study aims to grasp how internal marketing affects human resource effectiveness and employee performance in the public sector. Taking into consideration the results of the analysis of the 202 public servant, the implementation of internal marketing in the public organization will help to improve the overall performance of its staff members. To put it another way, the findings provide credence to the hypothesized favorable connection between internal marketing and employee performance as well as the efficiency of human resource practices. According to the findings, the efficacy of the human resources department in the local government is positively impacted by the performance of the employees. Even if there is a high correlation between charismatic leadership and employee performance, there is not a significant link between leadership and human resource effectiveness.

The effectiveness of the development of intermodal transportation within the framework of the «Intertran» project

Liana Chechenova[1], and *Natalia* Batalova[1,*]

[1]Emperor Alexander I St Petersburg State Transport University, Saint Petersburg, 190031, Russia

Abstract

Research background: Currently, the transport industry is facing non-traditional challenges for it, such as the need for digitization of transport services, increasing the mobility of transportation and reducing dependence on paper technologies for its design. At the same time, at the moment, only rail transport demonstrates high-quality development to the market with a reorientation of the geography of services and plays an important strategic role in the development of the eastern polygon, offering exactly what shippers need: regular shipments, the shortest possible time and stable prices despite the global restructuring of markets and economic fluctuations.
Purpose of the article: The purpose of this research is determination of the relationship between the expansion of the use of digital technology and the effectiveness of the development of intermodal transport. We confirm that the «Intertran» project allows railway companies, seaports and regulatory authorities to interact effectively.
Methods: The research methodology is based on the analysis of the order of electronic interaction between seaports and railways in the process of intermodal cargo transportation through seaports using electronic documents and data. The information base of the study is based on reports of Asian and European railway companies – members of the International Union of Railways, Russian and foreign forwarding companies, as well as data from the Federal Customs Service of Russia and foreign customs authorities.
Findings & Value added: As a result of the study, the participation of Russian railways in the development of innovations and the digital market environment is justified, the procedure for processing documents in electronic form within the framework of the «Intertran» project using mobile workstations is determined, the effects of the organization of pilot cargo transportation within the project are determined, the need to expand the digital environment of trust between participants in transport and logistics processes is established. The study confirms that the basis for the effective development of the «Intertran» project and the interaction of railway companies, seaports and regulatory authorities is a set of actions aimed at

JEL Classification: *L92; L98; O 32*

1 Introduction

In 2022, the change in the networks of routes and locations for the transportation of goods is taking place at a pace exceeding the record indicators of the pandemic crisis (SPARK, 2022). At the same time, it should be taken into account that fluctuations in economic activity lead to comparable fluctuations in demand for transport and logistics services. One can observe an extremely difficult situation in the maritime transportation market, where the shortage of container equipment due to unprecedented demand, as well as various force majeure circumstances, led to a jump in the cost of transportation and a decrease in the level of reliability of supplies. In turn, air cargo transportation, judging by the main metrics, managed to recover almost to pre-crisis levels by the beginning of 2022, but the long-term growth momentum was lost due to the sanctions imposed. In total, at the moment only rail transport demonstrates qualitative development to the market with a reorientation of the geography of services, which attracts the attention of shippers (Gulyi, 2022). Russian railways play an important strategic role in the development of the eastern polygon, offering exactly what shippers need: regular shipments, the shortest possible time and stable prices (Gulyi, 2020).

2 Methodology

The purpose of this study is to determine the relationship between the expansion of the use of digital technology and the effectiveness of the development of intermodal transport. Our task is to prove that the «Intertran» project allows railway companies, seaports and regulatory authorities to interact effectively.

It is necessary to take into account the advantages of cargo transportation by rail, namely:

- speed – today, for some companies, the proposed speed of delivery by rail is the only way to ensure mobility and speed of transportation (Kazanskaya and Shaykina, 2020);
- regularity – thanks to the uninterrupted and regular dispatch of trains, it is much more reliable to plan the loading of production with raw materials or the delivery of goods to retail (Zhuravleva et al., 2019a);
- safety – ensuring the highest level of cargo safety, which is confirmed by the absence of similar indicators in alternative delivery methods;
- environmental friendliness – statistics confirm that, taking into account the global trend towards the transition of companies to ESG approaches, the prospects for railway companies, infrastructure and transportation proper are quite optimistic.

The research materials were reports of Asian and European railway companies – members of the International Union of Railways (UIC), Russian and foreign forwarding companies, as well as data from the Federal Customs Service of Russia (FCS) and foreign customs authorities.

The basis of the developed information technology "Intertran" is the determination of the order of electronic interaction between seaports and railways in the process of intermodal transportation of goods through seaports using electronic documents and data (Fig. 1).
Figure 1. Intertran technology in the commercial sea port of Vladivostok

Source: author (2022)

It is necessary to note the preliminary trend of Russian railways in compliance with the principles of environmental protection and compliance with safety measures, which is enshrined in the Environmental Strategy of the Holding until 2020 and for the future until 2030 (Zhuravleva et al., 2019b). Currently, the company's share in atmospheric emissions, wastewater pollution and the creation of waste substances is no more than 1% compared to all organizations operating on the territory of the Russian Federation. At the same time, in 2019 in accordance with the corporate Program of measures to increase environmental responsibility, there is a reduction in atmospheric emissions, wastewater discharges and water consumption in the range of 3-4% compared to the previous period.

In order to reduce the negative impact of railway transport on the environment, the Holding actively uses "green" technologies for the electrification of track lines intended for passenger transportation. The economic effect of the implementation of energy-efficient projects amounted to more than 2 billion rubles in 2019, which indicates the leading positions held by JSC "Russian Railways" among international freight and passenger rail carriers in terms of energy and environmental efficiency.

If we consider the chronology of the Intertran project, we can note the key stages of its implementation. In 2016, the Economic and Social Commission for Asia and the Pacific (ESCAP) The UN publishes the results of a study aimed at optimizing intermodal rail services in Northeast and Central Asia. In 2017, Intertran was identified as a priority project for 2018 with the support of UIC APRA and international organizations such as ESCAP, OSZhD, CCTT. In 2018, the vector of further development of the project in terms of its practical implementation has been established. In 2019 Information technologies have been developed and implemented for the Intertran project, as well as pilot transportation on the Yokohama – Vladivostok – Silicate route (Fig. 2).

Figure 2. Pilot cargo transportation route

Source: author (2022)

Determining the relationship between the expansion of the use of digital technology and the effectiveness of the development of intermodal transportation, the results of the study of the expert group for 2020 on the topic "Legal regulation of multimodal transportation in the Asia-Pacific region" were taken into account, which made it possible to expand the scope of paperless technologies in terms of freight transportation by rail and identify priority areas for further work in this area, which is also reflected in the our research.

3 Results

3.1 The participation of Russian railways in the development of innovations and the digital market environment is justified

The pandemic crisis, shifting markets, and economic fluctuations as a result of the sanctions imposed accelerated the general trend of digitalization of cargo transportation and logistics activities. In the context of a sharp increase in the importance of the railway in international communication, the development of integration processes in the field of digitalization in the space of Asian economic cooperation is one of the most important areas of development. Digitalization of processes can provide a reduction in the cost of transportation, as well as an increase in speed and reliability, which will allow to induce a significant share of additional volumes (Volykhina, 2021). In this situation, a practical solution may be an additional expansion of the digital market environment through the active implementation of the Intertran project as an integrator of the transport and logistics space in order to unite the changing geography of transportation (Zhuravleva et al., 2019b).

3.2 The procedure for processing documents in electronic form within the framework of the Project using mobile workstations has been established

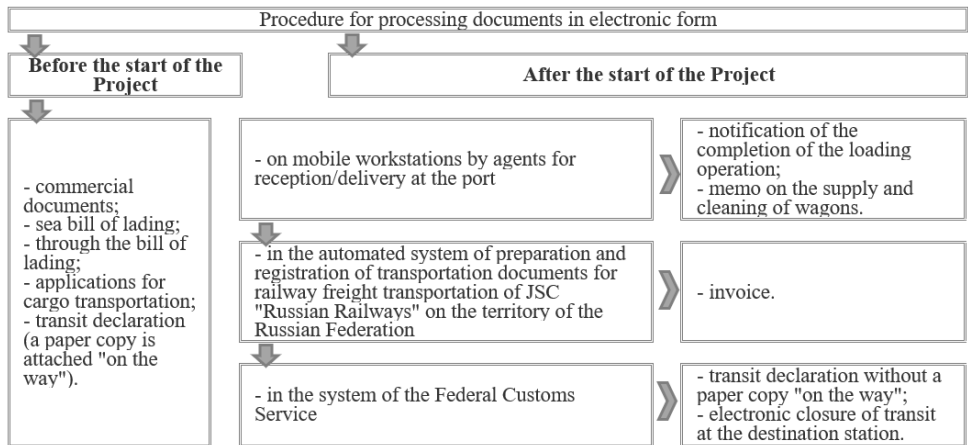
An additional factor in the growth of digitalization of technological processes of cargo transportation in JSC "Russian Railways" is the development and implementation of a domestic IT solution that allows processing documents in electronic form at ports when receiving cargo for departure and its delivery (Fig. 3).


Figure 3. Features of processing documents in electronic form

Source: author (2022)

3.3 The effects of the organization of pilot cargo transportation within the framework of the Intertran project are determined

The creation of the Intertran information technology and the development of a consistent project implementation plan were carried out by the working group of JSC "Russian Railways" and TG "FESCO" on the development of intermodal transportation using electronic document management. The work carried out made it possible to carry out a pilot shipment of containers from the Japanese Port of Yokohama, through the Port of Vladivostok to the Silicate station of the Moscow Railway.

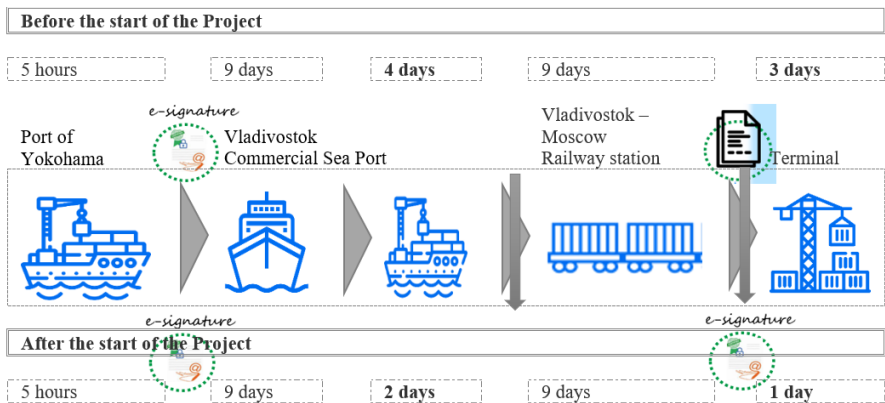
The pilot cargo transportation scenario within the framework of the Intertran project provides for the implementation of practical measures for the introduction of electronic document management in intermodal transportation, as well as the creation of a unified environment for information exchange in order to ensure the automation of business processes in railway transport. This is an additional incentive that increases the attractiveness of through intermodal rail transport for shippers and freight forwarders (Fig. 4).


Figure 4. The sequence of processing documents in electronic form

Source: author (2022)

Thus, the main positive effects of the Project implementation include a reduction in the total cargo handling time by 4 days and a reduction in total costs for participants in the cargo transportation process.

3.1 The necessity of expanding the digital environment of trust between participants in transport and logistics processes has been established

It should be noted that the jump in cargo transportation volumes during the pandemic crisis showed the limited capabilities of the railway infrastructure – the bottleneck, first of all, is the capacity of checkpoints (Tomicova et al., 2021).

Undoubtedly, the speed of transportation is significantly reduced as a result of downtime at the customs border. At the same time, one of the strategic goals of the development of JSC "Russian Railways" is to accelerate the movement of trains with a reduction in transportation time. But achieving this goal is difficult if the train will stand at the border, despite the introduction of digital technologies into the work of the Federal Customs Service of Russia, for example, electronic customs transit (Gudkova et al., 2015).

The reasons for this problem lie in the presence of a direct connection between the introduction of paperless technologies and document management, since the current paper technology is actually digitized and albums of electronic document formats are created for each participant in cargo transportation. In this regard, it is proposed to create a unified digital environment of trust between participants in transport and logistics processes with the possibility of exchanging meaningful data within paperless technologies for all participants, including state bodies that operate exclusively with the necessary data to ensure control functions. Since the issue of the development of multimodal transportation has recently become particularly relevant, the approach of exchanging significant data significantly simplifies the transportation process and increases its mobility.

4 Discussion

Undoubtedly, the shift in the stereotypes of digital development will lead to the transformation of production and consumption technologies, which, in turn, will affect the emergence of new business models of transport companies and a change in the structure of the cost of transport services

The main discussion on the goals and essence of future trends in the development of rail transport, shown by the authors (Guliy et al., 2019), reflects the necessary key indicators of sustainable development of rail transport based on the use of program and planning documents and confirms that the problem of digital development is of great importance for the global and national economies and coordinated actions between them. At the same time, the importance of the SDGs in the formation of relations is emphasized: developed and developing economies aimed at partnership and management of agreed SDGs in the interests of global growth.

The analysis of the impact of the digitalization process on the business model of global corporations, economic growth and business quality revealed the most promising ways of digitalization development in global corporations: the introduction of digital automation, during which the existing process in the traditional business model is digitized; the emergence of new IT services that improve the traditional business model; digital transformation of the traditional business model into a new one with the core of the digital platform. It should be noted that the authors proposed a visual model for monitoring the digitalization process within the company along with technologies that change the structure

of the global market through an active strategy and behavior of the company (Tretyak et al., 2021).

In recent years, many empirical studies have studied the impact of intelligent technologies on traffic control. Most of these studies were devoted to the creation of experimental models using various types of software. In particular, the authors (Zhuravleva et al., 2020) propose an agent-based traffic model and prove the possibility of reducing the average waiting time by 2.5 times. Based on these results, as well as the pilot implementation of the algorithm on other infrastructure facilities will allow achieving a positive effect with the help of intelligent traffic control, which is part of the global concept of intelligent logistics.

The methodology of economic evaluation of the implementation of distributed data registry platforms in multimodal transportation is presented in (Gulyi, 2020). Analysis of trends in the multimodal transportation market, in particular the European segment, allowed us to systematize the effects resulting from the introduction of block chain in transportation on the railway network, indicating the sources of their occurrence and quantification for the railway complex, taking into account global integration. The results obtained are in demand by managers of transport companies, development specialists and analysts who evaluate digital technologies in transport.

In the context of the ongoing research, an empirical study conducted to evaluate and analyze algorithmic control and technological guidance of connected and autonomous use of vehicles is undoubtedly significant (Lyakina et al., 2019). The authors took as a basis the results of the assessment regarding the technologies of automated vehicles and their impact on future mobility, the expected public benefits from autonomous vehicles. The work fills an important gap in research, since the proposed model contains a clear formulation of structural equations and is of interest for further research.

5 Conclusion

The conducted research confirms that the basis for the effective development of the Intertran project and the interaction of railway companies, seaports and regulatory authorities is a set of actions aimed at:

- electronic interaction with customs authorities at the port when declaring goods and using electronic transit declarations;
- the use of electronic invoices (paperless technology) in the processing of railway transport documents;
- optimization of processing of technological operations at the railway station using mobile workstations;
- the passage of the customs transit procedure in electronic form by the customs authorities of the destination on the territory of the Russian Federation without providing documents on paper.

A new vision for the further development of digitalization through the introduction of paperless technologies with a focus on intermodal transport appeared in 2016 within the framework of the UNESCAP project "Development of uninterrupted intermodal transport with a railway element in Northeast and Central Asia to strengthen Euro-Asian transport links" (Poliak et al., 2021). This situation can be considered as the primary "pilot" of the concept for the development of paperless technologies. For Russian railways, participation in the «Intertran» project is not only a project aimed at developing the Company's digital services, but also a contribution to the implementation of global development goals in terms of digital transformation.

Abstract

Research background: The growing threat of COVID-19 virus, known as coronavirus, is affecting companies and investor communities around the world. The global and interconnected nature of today's business environment poses a significant risk of disrupting global supply chains, which can lead to significant revenue losses and adversely affect the global economy. The impact on the global economy may increase depending on the extent of the geographical spread of the virus. But the pandemic has already adversely affected the entire global economy.

Purpose of the article: This paper focuses on the initial actions taken by the European Central Bank (ECB) to mitigate the impact of the pandemic. The first section emphasizes the context; The global spread of the virus has led financial markets into turmoil, while blocking measures implemented by countries to mitigate the spread of the virus have led to large economic losses in the short term.

Methods: Mix research technique has been used. While qualitative research entails in-depth literature readings and reports, quantitative analysis entails presenting data via graphs and tables

Findings & Value added: Following this research, the link between the Covid-19 pandemic and the magnitude of the economic system, both at European and global level, was found. The article adds value through the analysis performed at macroeconomic level, by interpreting statistical data related to this phenomenon of great relevance and notoriety that has brought major changes in all areas of socio-economic life..

1 Introduction

Metaphorically, the crisis shows us, from time to time, most often against our will, that life is dangerous, but also that life has priority (Ladaru et al., 2022). And even if we do not like confronting it at all, because it suddenly forces us, as it happens now, the radical change of the status quo, the crisis is an integral part of our lives (Belostecinic et al., 2022).

Our individual and social existence could not be conceived in the absence of crises, which play the role of extremely valuable variables in everything we are today and what we will become tomorrow (Popescu et al. 2021). For this reason, we can characterize crises as natural and normal in the development of our existence having an extremely important role in our evolution and maturation as individuals (Balu et al., 2021).

In order to achieve its main objective- maintaining price stability- the ECB has pursued three main objectives; ensuring a sufficiently accommodative overall position, supporting market stabilization to protect the transmission mechanism and providing ample liquidity to the central bank, in particular to maintain the provision of credit (Aalbers, 2016). Asset acquisitions have been intensified, both within the existing asset acquisition program and by the launch of a new temporary pandemic emergency procurement program (Burlacu et al., 2022). The ECB has also provided banks with more opportunities to borrow liquidity in its long-term refinancing operations, while easing their collateral requirements. Emphasis is placed on the motivation, purpose and impact of these measures rather than on their technical details (Sokol, 2017).

2 Monetary policy measures adopted by the European Central Bank in the context of the pandemic

In early 2020, the world was turned upside down by a new viral infection called COVID-19, the spread of which the World Health Organization (WHO) declared a pandemic on March 11 (Baumöhl et al., 2020). The virus combines three shocks: health, financial and economic, causing one of the deepest crises ever seen in peacetime. Governments around the world have quickly taken unprecedented steps to fight the pandemic, with the main priority being to limit the virus, followed closely by limiting financial panic and economic consequences, in which they have been helped by central banks and supervisors (Lane, 2021).

In these circumstances, the Governing Council, at its monetary policy meeting on 12 March 2020, decided that a comprehensive package of monetary policy measures should be adopted. It aimed, on the one hand, to mitigate the risk of sharp declines in liquidity and credit, by maintaining significant volumes of liquidity in the banking system and protecting the flow of credit to the real economy and, on the other hand, maintaining the accommodative direction of monetary policy. avoiding the pro-cyclical tightening of financing conditions in the economy.

At the beginning of the crisis, the orientation of monetary policy in the euro area was already very accommodative. Since the end of 2011, the ECB has continuously reduced its interest rates, with its main policy interest rate - the deposit facility rate (DFR) - hitting a record low of - 0.5% since September 2019. In addition, , acquisitions of assets under the ECB's Asset Acquisition Program (APP) was resumed in November 2019 at a monthly rate of EUR 20 billion. In addition, the ECB's early guidance ensures that a very light policy is maintained until inflation in the euro area converges strongly towards the target below, but close to 2% in the medium term.

To support the banking channel in a world of negative interest rates, the ECB also launched a third series of long-term refinancing operations in September 2019 - the so-called TLTRO III - on more favorable terms than before. originally planned. While the maturity of

operations was extended by one year, loan rates were also reduced, to the interest rate on the deposit facility (DFR), or -0.5% (Borri and Di Giorgio, 2021).

2.1 Peep-pandemic emergency purchase programme

There was a rapid deterioration of the situation due to the covid pandemic 19 and it was decided to launch a new temporary asset acquisition program- the pandemic emergency purchase program (Mewes and Broekel, 2020). Benefiting from an overall package of EUR 750 billion, PEPP was to include all categories of assets eligible under the Asset Purchase Program (APP).

The PEPP was introduced in 2020 and all categories of assets eligible under the PPA are also eligible under the PEPP. For purchases under the PEPP, a derogation was granted from the eligibility requirements for debt securities issued by the Hellenic Republic.

PEPP aimed to play a dual role. First, it aimed to ensure the necessary degree of monetary accommodation so as to support price stability in the medium term by supporting the economic recovery following the pandemic crisis (Holston et al., 2017). Second, acquisitions under the PEPP were intended to be carried out in a flexible manner, allowing fluctuations in the distribution of procurement flows over time, depending on asset classes and jurisdictions.

The value of this program increased from 770 billion euros to 1,350 billion euros and eventually reached a total value of 1,850 billion euros, after an increase of 500 billion euros.
Figure 1. The evolution of the value of the PEPP program

Source: Own processing based on data taken from the website www.ecb.europa.eu

2.2 Targeted longer-term refinancing operations (tltros)

The Board of Governors has decided to conduct TARGETED LONG-TERM OPERATIONS (TLTROS) translated into Romanian in additional longer-term refinancing operations (ORTL) at an interest rate equal to that of the deposit facility. It also decided to apply, from June 2020 to June 2021, much more favorable conditions for all operations under the third series of operations aimed at longer-term refinancing (OTRTL III). The interest rate on OTRTL III operations has been reduced by 25 basis points, being able to fall by 25 basis points below the average interest rate on the deposit facility between June 2020 and June 2021 for all OTRTL III operations in progress during that period.

At the same time, the maximum total volume that counterparties were entitled to borrow in OTRTL III operations was increased to 50% of their stock of eligible loans. Accordingly, as an effective and immediate consequence of the additional ORTLs, banks were to lend on very favorable terms, effectively covering the period until the start of the recalibrated OTRTL III operations, which aimed to relax the financing conditions for banks in - in a more sustainable way, to support the flow of credit to the affected sectors and to avoid constraints

from the perspective of credit supply. In addition, due to these measures, the population and companies benefited from favorable financing conditions, with interest rates on bank loans in relation to both categories reaching historic lows, respectively 1.32% and 1.46% (Figure 2).

3 Impact of monetary policy measures implemented in the context of the COVID-19 pandemic

3.1 Impact of policy measures on financial conditions

This subchapter examines the impact of the ECB's response to the crisis, focusing on asset acquisitions and long-term refinancing operations (TLTRO III). The ECB's monetary policy response focused on addressing three key issues: (i) market stabilization, which is a precondition for avoiding fragmentation and safeguarding the transmission of monetary policy in the euro area; (ii) providing ample central bank liquidity to support lending to the real economy; and (iii) ensuring that the general position is sufficiently accommodative (Bernanke, et al., 2019; Burlacu et al., 2019).

As the severity of the pandemic crisis emerged, investors rebalanced their portfolios, causing liquidity to dry up in more securities markets and demand for safe-haven assets to increase (Altavilla and Giannone , 2017).

The sharp decline in stock and bond market indices, combined with rising market-based financing costs for firms, contributed to a significant tightening of financial conditions between mid-February and mid-March 2020 (Burlacu et al., 2021) . In this environment, there was a very tangible. the risk of adverse liquidity spirals and an overrun of asset price corrections in many markets, which would jeopardize financial stability and impede the transmission of monetary policy. In a monetary union, the increased perception of risk can

lead to a dynamic flight to safety in the form of reallocations in sovereign bond markets (Bodislav et al., 2020).

As sovereign yields are often the benchmark in setting asset prices and credit interest rates, the unfounded volatility of sovereign spreads affects the transmission of monetary policy in the euro area (Camous and Cooper, 2019).

At the same time, the provision of ample central bank liquidity to support credit flow to the real economy has also been key to the ECB's monetary policy response to the COVID-19 crisis (Radulescu et al., 2021). This is particularly relevant in the euro area, where banks play a key role in financial intermediation (Orzan et al., 2020).

The liquidity supply of the central bank comes in the form of targeted and non-targeted programs . With regard to the first, the recalibration of TLTRO III in April 2020 included a considerably more favorable interest rate for TLTRO III operations between June 2020 and June 2021. This followed the March 2020 decision to increase the maximum amount to which counterparties are entitled. . to borrow in TLTRO III operations.

Accordingly, banks indicated in the April 2020 euro bank lending survey that TLTRO III has a net relaxing impact on borrowers' terms and conditions and a net positive impact on their lending volumes, in particular on the volume of lending. expected loan over the next six months.

The changes to the TLTRO III terms were followed by a significant extension of central bank funding. In the June 2020 operation of TLTRO III, banks bid for a total of EUR 1 308 billion in TLTRO funds, which is the largest amount allocated to date in any lending operation. With regard to non-target programs, the ECB announced in March 2020 additional long-term refinancing operations (LTROs) to provide immediate liquidity support to the euro area financial system and, in April 2020, a series of pandemic emergencies. untargeted. long-term refinancing operations (PELTRO). PELTROs serve as a means of protection, helping to ensure sufficient liquidity and good money market conditions in response to the crisis.

Once the market stabilization and the provision of credit for the real economy have been achieved and the ramifications of the pandemic crisis on the macroeconomic outlook have become clearer, the June 2020 PEPP recalibration has further eased the direction of general monetary policy (Rossi, 2013). In line with the dual role of the PEPP in restarting the initial stages of monetary policy transmission and easing the broad monetary policy stance and in response to the downward revision of pandemic inflation on the horizon, the recalibration of the PEPP in June 2020 has further eased much the direction of the general monetary policy, in order to make it proportionate to the medium-term inflation outlook.

By extracting long-term investor risk through its acquisitions, the ECB strengthens the impact of its negative interest rate policy and forward guidance on rates by pushing down the middle and long ends of the yield curve.

3.2 Macroeconomic impact

Countering the tightening of the financial conditions facing the euro area economy in the face of the COVID-19 crisis, the ECB's policy measures have provided crucial support to the real economy and, ultimately, to price stability (Braun, 2020).

This support works in two major dimensions: (i) supporting the medium-term growth and inflation prospects and (ii) eliminating the risks of queuing around the baseline scenario.

In terms of supporting the medium-term growth and inflation outlook, ECB staff estimates that, taken together, the PEPP, the enlargement of the JPA and the recent TLTRO III recalibration will add about 1.3 percentage points cumulatively to real euro area real GDP growth. on the projection horizon and contributes about 0.8 percentage points cumulatively to the annual inflation rate over the same time horizon (see Chart B).

At the same time, while monetary policy usually acts with a transmission gap, the positive impact on consumer and business confidence created by swift and decisive action during a crisis should not be overlooked and can accelerate and support the transmission of monetary policy to growth and inflation (Bodislav et al., 2021) .

These estimates do not fully capture the benefits of avoiding feedback loops between the real economy and financial markets that may arise in an economic crisis such as that caused by COVID-19, in which the main contribution of monetary policy is to eliminate tail risks around the value of the basic macroeconomic perspective (Gräbner et al., 2020).

Econometric evidence indicates the existence of large nonlinearities in the macroeconomic response to shocks to financial conditions. In other words, the impact of a certain change in financial conditions depends on the state of the economy (Sarbu et al., 2021). This means that, under conditions of acute financial market stress, the presence of financial frictions and balance sheet constraints implies severe non-alignments that can translate into much greater contractual effects caused by tightening financial conditions.

Given the severity of the shock associated with the COVID-19 crisis, a tightening of financial conditions in the current environment is expected to have an impact several times greater than that captured by the average elasticities used in Chart B to quantify the policy impact (Swanson, 2021). Therefore, monetary policy measures aimed at counteracting such a deterioration in financial conditions would make a stronger contribution to price stability than is captured by the standard elasticities derived from the more normal conditions underlying the above quantification (Walter and Wansleben, 2020).

Overall, the ECB's measures have been an effective and efficient response to the COVID-19 crisis and are proportionate to the current conditions in fulfilling the ECB's price stability mandate (Basu and Bundick, 2017). The effectiveness of the ECB's measures is evident in improving the financing conditions for the general economy, and the implementation of a combination of asset acquisitions and TLTROs reflects the fact that they are effective instruments in the current circumstances.

In addition, they are proportionate to the severe risks to the ECB's mandate, the net impact of the COVID-19 crisis on the medium-term inflation outlook is expected to be disinflationary to a considerable extent. While the ECB continuously monitors the side effects of its policies, the arguments for monetary easing through the PEPP have been overwhelming, given that the ECB's objective of price stability would have been subject to further downside risks in the absence of such measures.

4 Conclusion

The inflation response reflects the exceptional circumstances we are in. These effects are expected to pass in the end. However, the pandemic has also introduced new trends that could affect the dynamics of inflation in the coming years. These trends could lead to both upward and downward price pressures.

Therefore, monetary policy must remain focused on safely targeting the economy in the event of a pandemic and on sustainably raising inflation to our 2% target.

In conclusion, a substantial degree of monetary policy adjustment was implemented during 2020 in order to counteract the negative impact of the pandemic. The comprehensive set of measures and their subsequent recalibrations were a key stabilizing force for the markets and contributed to the reversal of the tightening of financial conditions in the first part of the year.

The measures have proved effective in limiting the yields on sovereign bonds, which are the basis for financing costs for the population, companies and banks. They also helped maintain very favorable bank financing costs throughout the pandemic.

However, although policy makers have led the economy relatively well in the depths of the crisis, their task is far from over and may become even more complex.

Abstract

Research background: The relevance of the study lies in the fact that the era of technology today is spreading to the very heart of everyday existence and, thanks to this, is actively involved in the intersubjective construction of realities, clearly marks the planetary triumph of the cybernetic paradigm. An economic cybernetics model is a model created by applying economic cybernetics and modern control theory to identify and evaluate a macroeconomic system in order to realize optimal or suboptimal control over the macroeconomic system through computer simulation.

Purpose of the article: The purpose of the study is to consider aspects of the development of economic cybernetics in the world, as well as mathematical models and their comparative characteristics.

Methods: To create a model of economic cybernetics, the various concepts of management should be given clear economic meanings, taking into account the characteristics of the macroeconomic system. Treating it as a linear system is an approximation that introduces large errors and sometimes even economic fluctuations. Identification and simulation data are mainly obtained by periodic sampling, the available data is insufficient, the reliability is low, and in most cases, there are serious noise interferences.

Findings & Value added: The results of the study determined the generations of the development of cybernetics, as well as its economic models, including mathematical ones. The practical significance lies in the analysis of the paradigm and models of development of economic cybernetics in the modern world.

Keywords: *macroeconomics; mathematical models; control system; computer modeling; automation.*

1 Introduction

A person's desire to understand the world and manage it intelligently is the reason for the gradual development of the economy. This aspiration has led humanity today from conventional manufacturing to digital manufacturing. The first automatic regulator used in industry was the flying ball regulator, invented by J. Watt in 1769 to control the speed of a steam engine.

In the second half of the nineteenth century, many scientists began to study the theory of self-control based on mathematical theory, which had a positive effect on improving the efficiency of the control system (Boulding, 1956, Boulding, 2013). In 1868, J. Maxwell established a mathematical model for the differential equation of a flying ball regulator and analysed the stability of the system by solving the differential equation. In 1948, the mathematician N. Wiener developed "cybernetics", which has been continuously developing for more than half a century, and its content and research methods have changed greatly (Wiener, 1965). Briefly, the development of cybernetics has gone through three periods: the first stage is the classical period of cybernetics from the late 1940s to the 1950s, when the focus was on the study of autonomous automation and the solution of SISO-Single Input Single Output. System with one input and one output. Its main mathematical tools were differential equations, Laplace transforms, transfer functions, the time domain method, the frequency domain method, and the root locus method. The main problem was speed, stability and accuracy.

Based on Wiener's idea, medical scientists at Harvard Medical School discussed scientific methods with mathematicians, physicists, and engineers. He emphasizes the interdisciplinary nature of his approach and refers to his work with Vanivar Bush and his differential analyzer (primitive analog computer), as well as his earlier reflections on the functionality and principles of future digital computers. He traces the origins of cybernetic analysis to the philosophy of Leibniz, citing his work on universal notation and the calculus of reasoning.

In the 1960s, focused on solving the problems of controlling MIMO-Multi-Input Multi-Output systems in block automation and biological systems. The instruments were: first-order differential equations, matrix theory, state-space method, variational method, maximum value principle, dynamic programming theory.

The emphasis was placed on optimal, stochastic and adaptive control, the main control device of which was an electronic computer (Piketty and Goldhammer, 2017, Piketty, 2021). From a cybernetic point of view, man is the most ingenious and flexible control system. He is good at responding correctly to changing conditions. How to apply human intelligence to a real automatic control system is an important problem (Mason, 2021).

Since the 1970s, people have not only solved social, economic, managerial, environmental and other systemic problems, but also formed a new discipline to solve the simulation of human brain functions. The science of artificial intelligence, which is the frontier of the development of cybernetics, and the development of computer technology provide a solid foundation for artificial intelligence. People improve artificial intelligence with the help of computers' powerful information processing capabilities and use it to simulate the human brain (Beer, 1993).

Information is an important characteristic of an organizational system, it allows the system to achieve self-regulation and is the main way of communication between systems and the environment. System, information and management are inseparable (Snowdon, 2008 ; Leijonhufvud, 1968).

2 Methodology

The methodological basis of the study was the following approaches to the study of this topic: systemic, formal-model, dynamic. The system method introduced the relevant theories and mechanisms of economic cybernetics, paying special attention to the prerequisites for the development of economic cybernetics, the creation of models for managing the economic system, the analysis of their state space, the analysis of the stability of economic structures and manageability, highlighting the problems of performance and observability, feedback control strategies for economic systems, optimal management strategies using appropriate tools. This methodology made it possible to consider the system as a simple control with negative feedback of one control variable, but due to the limited understanding of the economic system within the framework of the model of an indefinite structure in accordance with the characteristics of the input variables. The systems research method is a further development of the decision research mechanism and consists in studying how the external economic structure adapts and coordinates in order to ensure smooth development. This is a process in which the elements of the mechanism observe the market from time to time, detect and evaluate various factors in a timely manner.

3 Results and discussion

The mass globalization of the world's economies and the digitalization of information processes and the multiplication of data, the search for the effectiveness of processes has eliminated all anthropological questions. However, in its way of collecting, sorting, analyzing and presenting information, managerial control causes a certain approach to people, society and their environment. Key aspects of his considerations are such tasks: to integrate economic, social and environmental information; be a node through which digitized information passes, a control point that ensures the reliability and relevance of the information transmitted; make sense of abstract information, turning numbers into a meaningful story for all stakeholders of the economic system. Cybernetics also translates the desire to mathematize knowledge about organisms not in the biological sense, but at the mechanical level of an organized structure that implies a connection between its parts. This is primarily a semantic issue, because mathematics, compared to words, promotes clarity and precision through its symbolism. Thus, the concepts of correlation and pattern echo each other and oppose the chaos generated by the general law of entropy, where all organisms function according to an individual model that structures the mechanisms of their bodily apparatus. Through their method of structuring phenomena, both release the individual from his metaphysical conception in order to rationalize and model him mathematically (Nordhaus, 2015). They see form as movement, defending genetic geometry, which alone can give the affirmative or perfect definition of any mathematical object and even more of an individual that is part of physical and real beings.

The regular increase in the computing power of electronic machines makes it possible to simulate more and more natural or artificial systems. This processing power is all the more effective when an abstract mathematical model is available that summarizes the dynamics in a few symbols. The concept of a controlled system and regulation also allows the formation of many technical, economic or social systems. From a completely different point of view, scale-invariant systems in which "big is like small" seem to be approximated by "fractal geometry". One might wonder what good work is on the dynamics of such systems. In addition, economic cybernetics introduces a dual mathematical model to describe, on the one hand, the free evolution of the system, and, on the other hand, the interactions between the observer and the system. For more than a century, management tools have been able to meet the needs of increasingly complex process control. The need to delegate decision making as

closely as possible to actors while maintaining a global vision of processes has led to the development of numerous tools ranging from budgetary control to balanced scorecards, including costing and reporting. But managerial control is not only a tool for coordinating processes, but also a tool that shapes organizational processes and influences social and environmental interactions.

In order to create a model of economic cybernetics, clear economic meanings must be given to various concepts of management. The creation of a model of economic cybernetics must fully take into account the characteristics of the macroeconomic system. The macroeconomic system is often constrained by the uncertainty of people and economic phenomena, and is essentially a random non-linear structure. Considering it as a linear system is an approximation that introduces large errors, and sometimes even economic fluctuations (Bayro-Corrochano, 2019). Identification and simulation data are mainly obtained by periodic sampling, the available data is insufficient, the reliability is low, and in most cases there are serious noise interferences. The macroeconomic system belongs to the category of large systems, which, as a rule, are difficult to decompose accurately. The strong coupling of each subsystem often causes difficulties in mathematical processing. The stability, manageability and predictability of the economic system are the main discussions that go through the development of macroeconomics. System identification mainly studies the stability, controllability and predictability of economic systems. The choice of the optimal economic policy in macroeconomics is actually an optimization method. The essence of the optimization method is to find the optimization mechanism and element with a known system performance indicator and certain restrictions. Based on the mathematical model of a physical system, the mathematical description of problems is inherently complex, however, these important ideas can be found both in nature and in human evolution and human behavior: feedback, filtering, shock fluctuation system, system characteristics, optimization methods .

Mathematical modeling can deepen the knowledge of reality, using the mathematical apparatus not only as a description tool, but also as a research tool, where it is about emphasizing that mathematical formalization should reveal new facts that can bring closer to the essence of the phenomenon under study. Thus, it is mathematical formalism that is at the center of this concept of cybernetic modeling, since it has the amazing power, characteristic of the mathematics from which it is made, to discern in the dimensions what has gone unnoticed. However, if you use a computer to process this model, then automatically there is a "transcription" of the mathematical formulation on a machine that is able to solve and calculate it. The use of computers makes it possible to convince more experimenters of the need for a clear and precise formalization step. But, with the advent of computers, the change in the use of mathematical models, strictly speaking, is only quantitative in a more general sense, because mathematical modeling comes from a mathematical innovation of an essentially formal and logical type in a broad sense. That is, in terms of a set of categories that serve to connect signs and express mathematical relations, cybernetic thought goes so far that in this context it represents a fundamental epistemological update that allows you to go beyond binarism, the bivalent logic that has reigned in science and philosophy since the time of Aristotle, in favor of polyvalent or even continuous logic. The mathematical apparatus allows us to show that after reaching a certain critical threshold, the system can choose a new adaptive behavior. When the target to be reached differs from the existing output power, the system detects the difference and sends instructions to change the input in the desired direction (Youngblood, 2020, Perez, 2).

Feedback is now a commonly used concept in almost every field. In a system, positive feedback will cause the system to diverge, oscillate and become unstable, while negative feedback will cause the system to converge and keep the system stable. In economics, this state is called equilibrium. In fact, this means that there is a negative feedback loop in the

own system, and autonomous action brings it to equilibrium. The basis of cybernetic analysis is system identification, control, evaluation, appropriate macroeconomic modeling, macroeconomic control and regulation, and optimal policy and welfare analysis. Due to the application of feedback to the system, the system is kept in a stable state, in the economic field such a state is called equilibrium. Equilibrium was introduced relatively early in the economic field, such as the equilibrium price determined by the action of supply and demand. Regardless of the mathematical form or intuition, what this really means is that there is a negative feedback loop in her own system, and autonomous action brings the system to equilibrium. With the development of the economy, everyone understood that the state of equilibrium known in the past is a static concept and may even be a long-term concept. With the advent of Keynesianism, everyone gradually showed a strong interest in the short-term adjustment of the economy. From comparative static analysis to dynamic analysis, it can be described in cybernetic language: although the system itself has negative feedback, it can be autonomous in the long run (Medina, 2011 ; Moon, 2013 ; Zacarias, 2013).

A steady state is reached, but due to external shocks, it often deviates from the steady state equation. Even when the shock is too large, the system will deviate from the original equilibrium point, meaning the system is likely to be stable within a certain range of motion.

The economic system is essentially the same as other dynamic systems that can be described by mathematical language, it has its own characteristics, such as stationary and dynamic, which determine the static position of the system and the trajectory of the reaction under certain conditions of external shocks. This can be seen from the path of evolution of the classical theory of economic crisis. Initially, during the Great Depression, Fisher attributed the financial crisis to "over-indebtedness" and, based on this, proposed an explanation for the financial crisis and its consequences by the "debt deflation" theory of recession. According to it, a company overborrows at an early stage, when the economy cannot achieve the expected growth or asset prices fall, it is forced to facilitate and sell assets due to the inability to repay the debts due, or even go bankrupt and reorganize. The spread of this situation leads to a decrease in the growth rate of deposit money and the velocity of money circulation, which, in turn, leads to a decrease in the general level of prices. At a constant nominal interest rate, deflation will increase the real interest rate of debt and increase the debt burden of businesses, causing the economy to fall into a vicious cycle of "excessive debt - deflation - more debt - more deflation". When the economy enters a growth phase, corporate profitability increases, balance sheets improve, asset prices for companies and households rise, default risk decreases, and credit availability increases, which can expand investment (Dubberly and Pangaro, 2015). As a result, both the financial and economic systems enter a phase of growth. When the economy enters a downturn, corporate profitability deteriorates, balance sheets shrink, corporate and household assets shrink substantially, default risk increases, credit opportunities decrease, and output and profits also decline.

The term "filtering" comes from communication theory, which is a method of separating useful signals from received signals containing interference. The received signal corresponds to the observed random process, and the useful signal corresponds to the estimated random process. In engineering it deals with a series of signals, and in economic systems with a series of time series. Due to the limitations of observation methods and sampling periods, the data often contains a lot of noise, which also needs to be estimated by filtering. There are two types of filtering methods: the time domain method and the frequency division method. The time domain is the real time domain and the frequency domain is the mathematical construct after mathematical transformation. Time domain analysis uses the time axis as coordinates to express the relationship of dynamic signals. Frequency domain analysis transforms the signal into a frequency axis as coordinates for an expression. The time domain moving average method can smooth out fluctuations over a period of time, and high-pass filtering or

frequency-domain low-pass filtering can filter out signals in a specific frequency range. Although the proposal of a filtration theory was not originally intended for the purposes of economics, the ideas of a general filtration theory and the corresponding methods of information processing play a very important reference role in economics. The general theory of filtering offers a set of methods for extracting and analyzing the state of information confusion. The information referred to in economics differs from the information in communications and control, however, they have very similar descriptions of the nature of the phenomenon reflected by the information (Arca, and Mariategui, 2021 ; Mancilla, 2020).

There are two sources of system fluctuations. One is determined by the internal equation of the system, that is, the fluctuation state is determined by positive feedback and negative feedback within the system. The other is an externally applied shock signal. The nature of the impact depends on the mathematical form. For example, a pulsed shock signal has strong differential characteristics, and this response decays exponentially with time. Economic volatility is also a fundamental issue in macroeconomics, and the origin of volatility is a key issue. Fr. Hayek believes that economic volatility is in itself the greatest challenge to equilibrium theory. The value of each economic component in economic fluctuations is not the same, and even in different countries the difference is also very large. For example, in multiplicative economies, fluctuations in demand are the main macroeconomic factors, and supply factors are relatively stable, while in developing countries, economic fluctuations mainly occur on the supply side - investments. Economics basically divides the process of exogenous shocks into: demand shocks, exogenous spending shocks, risk premium shocks, investment technology shocks, supply shocks, total factor productivity shocks, markup shocks, and policy shocks. In the basic DSGE (Dynamic Stochastic General Equilibrium) mainstream model, developed on the basis of the RBC model, negative shocks are amplified through six transmission mechanisms: intertemporal substitution, uncertainty, irreversible investment, labor adaptation costs, concentration over time, and the role of financial markets (Helvey, 1971).

Dynamic performance refers to the relationship between output and input during system operation, which can be expressed by a differential equation. If it is a discrete time series in economics, it can be expressed as a differential equation. In particular, the system deviates from the equilibrium point. To the characteristics of the movement of the return to the equilibrium point, the measurement indicators are the speed of adjustment, stability and the amount of overshoot. The static response characteristic refers to the state of the system when it is in equilibrium, and most of the time refers to the steady-state error, that is, fluctuations at the moment of equilibrium. In fact, this is a fundamental principle that is used in everyday life. In order to quickly adjust the system to the ideal equilibrium point, more feedback control can be applied to the manipulated variable so that the dynamic performance of the system is ideal, but this will cause even poor static performance of the system to be overshooted, and even make it have poor static performance (Lorentz 2002). The system deviates from the equilibrium point. Therefore, there is no need to apply excessively large and strong signals to immediately or directly bring the system to the desired state. If an excessive external force is applied, the system will deviate from stability. This concept was first proposed by Hall in 1907 and some engineers. Hall, comparing the behavior of political economists, believed that the reasonable operation of the law of supply and demand must allow fluctuations, and the operation of the system requires a certain degree of fluctuation, which is a very general principle.

Arithmetic or algebraic calculations are, by their very nature, fixed and deterministic. Given certain data, certain results inevitably follow. These results do not depend on anything other than the originally received data. And the question to be decided is, or must be, moving towards a final decision on a number of infallible points which are not subject to any change and are not subject to any modification. Having accepted this, one can easily imagine the

possibility of constructing a mechanical part, which, taking a starting point in the data of the problem being solved, will continue its movement regularly, progressively, without any deviation towards the required solution, since these movements, no matter how complex they may seem, will be finite and deterministic. The thesis is that computation is mechanizable. For any calculation, it is possible to design a machine that can perform it (Shanken, 2003). Identifying computation with the operation of a machine is not, strictly speaking, demonstrable, but represents a kind of axiom which is justified by reflections on the concept of computation, and which, one might say, defines this concept. The well-known mathematician and economist P. Dupin summarizes the difference between analysis and mathematics with the following formula: "any calculation in itself is not an analysis." Calculus seems to represent the essence of mathematics. Thus, in its very extension, the notion of calculus retains a certain vagueness. This also applies to the machine that has to perform these calculations.

The design of self-regulating control systems for a real-time planned economy was studied by the economist O. Lange, the cyberneticist V. Glushkov, and other Soviet cybernetics in the 1960s. By that time, information technology was advanced enough to make computer-based economic planning possible. Cybernetics, developed simultaneously with the mathematical theory of communication by engineer K. Shannon, is part of the development of the so-called information theory, where it was determined that some economic systems are unstable without feedback, but if the economic system can be controlled, then the closed system can be stabilized due to feedback. In problems of optimal control of economic systems, many equilibrium states are saddle points. For a two-dimensional system, its structure is assumed to have two real eigenvalues, one positive and one negative. The straight line of the overbalance point, in which the eigenvector corresponding to the positive eigenvalue is located, is called the unstable shoulder, and the straight line of points is called the stabilizer shoulder. Influenced by social development, this era was indeed a period of development of "system analysis" and "system" in its applications, sometimes the most bizarre. However, it is she who encourages to strengthen their contacts with cybernetics. It should be remembered that the mathematician N. Teodorescu was then an influential person in the field of applied mathematics. A whole school of cybernetics soon formed around him. In 1963, building on his interdisciplinary experience in applied mathematics dating back to the late 1940s, he published a work in Romanian that extolled the virtues of this new method of formalization, mathematical modelling. He defended the idea that cybernetic modelling deals with a new stage of mathematization and that it should be considered as a break with the previous stage of biometrics (Geipel, 2019, Baylis, 1971).

In the same way, the pattern of Wiener, the founder of cybernetics, includes the dynamic principle of feedback, without which the organism as such would not exist. This is why the form of the individual is a geometric abstraction that can only be understood paradoxically by refusing to separate its element from the efficacy of physical mechanisms. The mathematical rule that governs the functioning of an individual, contrary to vision, is produced by the activity of that organism, and not vice versa. Thus, we are not talking about translating a quantitative relation, but about expressing a qualitative model characterized by its dynamism, and then the difficulty lies in the algebraic form of this relation or individual model, since the mathematical language is fixed by numerical values. A ratio, and even more so a regularity, is not so much a number as an operation, that is, a logical relationship that a mathematical function can completely restore. Indeed, the logarithm embodies both the dynamic aspect of mathematics and the possibility of taking into account individual homeostasis. On the other hand, feedback is the process of stabilizing the initial state or regulating towards an acceptable state, which allows a particular system to respond to the action of an external element, while maintaining itself. However, the trends of conservation and increase are paradoxical, but complementary, and they manifest themselves in the cyclic

causality of the logarithmic function. The logarithm causes the repetition of the same operation, a dynamism that preserves the logic according to which a number raised to a certain power increases its value. Thus, mathematization through the apparent immobility of an algebraic function, which has nothing incompatible with the dynamism of its curve variations, contributes to mastering the mechanisms of the economy (Warburton, 1955).

Thus, models of economic cybernetics are always associated with an epistemological context, a set of scientific as well as literary discourses that make its conceptualization possible. Digital post-humanity is primarily a paradigm shift in relation to the development of computing, and not a modification of the modern look by technology. The corresponding determinism is related to the fact that the dynamic model can be translated into the form of mathematical relations, where computer algorithms act as a means of digitizing the system by restoring processes that create order and a single sequence of ideas, as well as actions arising from them. From this it follows that the system is equal to the lines of the program in its interactions with exteriority, which modifies it retroactively without violating its integrity. In economic cybernetics, one should not see the threat of dehumanization controlled by the economic system, which provides only for productivity and inhuman use of a person. As for the digitization of personality, it has nothing to do with virtual imitation and the totality of physical and mathematical processes that form it on a material basis, the infinite variability of which reveals a fundamentally plastic individual. The digital system is not dematerialized and its existence is internally connected with the existence of an infinitely open and developing body.

4 Conclusion

The mathematical difference between economic systems allows us to determine their dynamic model, program. This operational image, in contrast to the digital aspect, fixes the structure of a functional system, which can be translated into an algorithmic form in order to be transmitted, reproduced or multiplied. Her affective interactions also reveal the plasticity of the material form, capable of radical transformation. Considering the system as a computer seems obvious, especially in regard to the workings of thought, because automatism goes far beyond the mechanisms of the body alone. A computer is an information processing software structure, that is, it works on the basis of a series of instructions that cause it to perform operations in a certain way in a certain order, as indicated by its etymology. The connection with cybernetics is obvious, which explains why memory is understood as a certain sequence of ideas enveloping the nature of things outside the human body. Indeed, for cybernetics there is no absolute distinction between transmission types. By mathematizing what makes explicit the notion of a model, the system can be communicated in such a way that the hypothetical instrumental mechanism can rearrange the mechanical elements appropriately and is able to continue the processes that existed before.

Factor analysis of Summary Innovation Index

Katarina Janoskova[1,*], and *Pavol* Kral[1]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: There is no doubt that innovation is an important source of competitiveness, economic growth, as well as the image of each country. Therefore, it is necessary to measure it and monitor the development of the measured values over time. There are several indicators to measure innovation and innovation performance of a country. European innovation scoreboard provides a comparative analysis of innovation performance in EU countries, other European countries, and regional neighbours. It assesses the relative strengths and weaknesses of national innovation systems and helps countries identify areas they need to address.
Purpose of the article: The main purpose of the article is to analyse the main areas of Summary Innovation Index (human resources, attractive research system, digitalisation, finance and support, firm investments, use of information technologies, innovators, linkages, intellectual assets, employment impacts, sales impacts, environmental sustainability) that affect the final SII value and to find out whether it is possible to define a smaller number of factors influencing the SII value based on their mutual correlation.
Methods: To achieve the purpose of the article the factor analysis is applied. Input data consists of the values of individual SII areas of Slovakia for the period 2014 – 2021.
Findings & Value added: A large number of variables influence the innovation performance of countries. Their monitoring and management is therefore very difficult. Factor analysis will makes it possible to define a smaller number of factors representing the analyzed variables, which can facilitate their management and analysis.

Keywords: innovation, innovation performance, factor analysis, Summary Innovation Index

1 Introduction

Globalization increases competition and competition contributes to the increase in innovation. Globalization brings new opportunities (Vagner, 2016) and innovation is the way to take advantage of these opportunities. Innovation are characterized by great economic value (Gavurova et al., 2021). Global competitiveness has been one of the major goals of countries worldwide in the last few years, especially after the financial crisis emphasized the need for new strategies, innovations and dynamics in the economic and business environment (Dima et al., 2018). The innovative activity is perceived to be the source of competitiveness and economic growth. The innovation performance varies from one company to another and from one country to another, being influenced by a variety of factors (Sipos et al., 2014; Nica et. al., 2017; Popescu, 2017; Popp et. al., 2018; Regnerova & Regnerova, 2017). It is very difficult to measure the innovative activity of a country. The innovative activity consists of several different areas that affect the innovation performance of the country. There are two the most famous ways to measure and evaluate the innovation performance of the country: global innovation index (GII) and summary innovation index (SII). Our research focuses on the summary innovation index (hereinafter the SII) only, and the aim is to analyze the main areas of Summary Innovation Index (human resources, attractive research system, digitalization, finance and support, firm investments, use of information technologies, innovators, linkages, intellectual assets, employment impacts, sales impacts, environmental sustainability) that affect the final SII value and to find out whether it is possible to define a smaller number of factors influencing the SII value based on their mutual correlation. The European Commission detailed the most popular ways for the European Union countries to support creative activities at the European level in order to achieve the level of performance recorded in this area by the United States and Japan following the positive impact of innovation. In order to measure the level of innovation performance and apply some useful techniques to increase its impact on the macroeconomic level, an aggregate indicator of innovation (SII) was developed.

SII is synthetic indicator expressing innovative performance of countries in the form of a single value, but on the other hand it is the source of a lot of data that can be analyzed. Many scientist try to analyze in their research the factors that influence the innovation performance of countries to the greatest extent. Svagzdiene and Kuklyte (2016) analyzes factor which have impact for SII in Germany, Estonia and Lithuania, Scholleova (2009) deals with analysis of SII in Czech Republic, Janoskova and Kral (2019) implemented an in-depth analysis of the SII in the V4 countries, and many others (Stec, 2009; Kowal et al., 2020; Murswieck et al., 2020; Onea, 2020; Dworak, 2020, etc.) . Innovative performance is affected by many factors, therefore the factor analysis will be used to analyze this field of research. Factor analysis is an extremely popular model for scale development prior to other modeling in much research in business and the social sciences (Iacobucci et al., 2022). There are two main technically distinctive approaches to exploratory factor analysis: i) common factor analysis and ii) principal component analysis. Factor analyst use principal component analysis more frequently because they believe that principal component analysis could yield less accurate estimates of factor loadings compared to common factor analysis but most often produce similar pattern of factor loadings, leading to essentially the same factor interpretation. Jung and Seo (2013) realized a simulation study to evaluate the relative performance of the two approaches in terms of recovering factor patterns under different experimental conditions of sample size, overdetermination, and communality. Their results show that principal component analysis performs better in recovering factor for small sample sizes. Furthermore, this tendency has been shown to be more pronounced when there are a small number of variables per factor. Therefore, for the need of our research, we implemented the principal component analysis.

2 Methodology

The main purpose of the article is to analyse the main areas of Summary Innovation Index (human resources, attractive research system, digitalisation, finance and support, firm investments, use of information technologies, innovators, linkages, intellectual assets, employment impacts, sales impacts, environmental sustainability) that affect the final SII value and to find out whether it is possible to define a smaller number of factors influencing the SII value based on their mutual correlation. Input data consists of the values of individual SII areas of Slovakia for the period 2014 – 2021 and the IBM SPSS Statistics 26 was used to the calculations.

To achieve the purpose of the article the factor analysis is applied. Factor analysis is a statistical method used to describe variability among observed, correlated variables in terms of a potentially lower number of unobserved variables called factors.

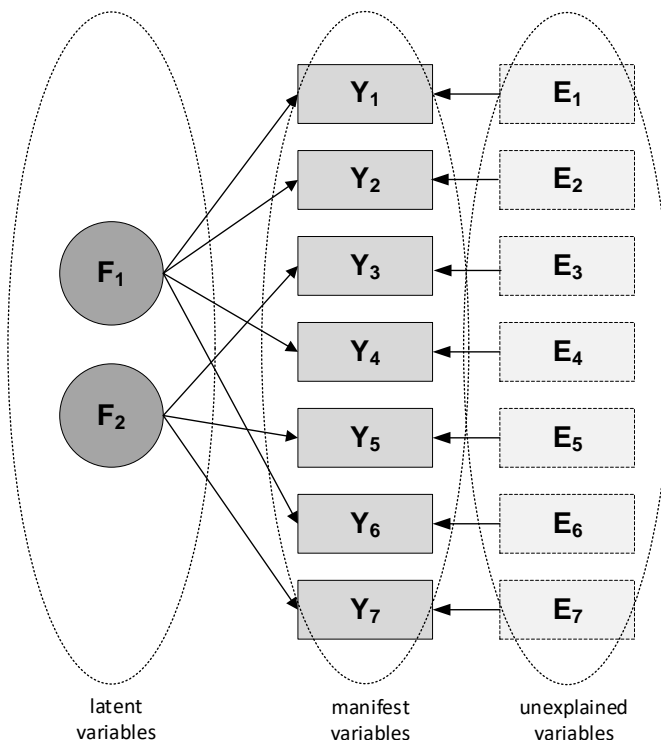
Factor analysis is based on a p-dimensional data set $\begin{pmatrix} y_{11} & \cdots & y_{1p} \\ \cdots & \cdots & \cdots \\ y_{n1} & \cdots & y_{np} \end{pmatrix}$. The basic principle of factor analysis is that each of the observed random variables $Y_j (j = 1, \ldots, p)$ can be expressed as the sum of a linear combination of a smaller number of m unobservable (hypothetical) random variables $F_1, \ldots, F_m$ – the so-called common factors and another source of variability $E_j (j = 1, \ldots p)$ – the so-called specific (residual) components. The variables Y_j are sometimes called manifest variables and the factors $F_1, \ldots, F_m$ are called latent variables (Figure 1).


Figure 1. Illustration of factor analysis model

Source: own processing

We assume that the model $Y = \Lambda F + E$ holds for the random vector $Y = (Y_1, \ldots, Y_p)'$, where $F = (F_1, \ldots F_m)'$, $E = (E_1, \ldots E_p)'$ a $\Lambda = (\lambda_{jk})$ is unknow real matrix of type $p \, x \, m$. Matrix Λ is called factor matrix. E_j is random deviation from the exact model corresponding to the jth variable, where $j = 1, \ldots, p$. The element λ_{jk} of factor matrix is the factor weight (load) of the kth common factor corresponding to the jth variable, where $k = 1, \ldots, m$. The factor analysis model expresses the relationship between latent variables and manifest variables. Coefficient λ_{jk} is the conversion coefficient of F_k to Y_j.

The Kaiser-Mayer-Olkin statistics (KMO statistics) i sused to assess whether correlations between variables $Y_1, \ldots Y_p$ are explained by means of other variables $F_1, \ldots F_m$. KMO statistics is based on the sample correlation and partial correlation coefficients of variables $Y_1, \ldots Y_p$. KMO statistics reaches takes on values between 0 and 1. To assess whether it makes sense to implement factor analysis, we can use the following values (tab. 1).

Table 1. KMO test – levels of acceptance

KMO value	Level of acceptance
$KMO \geq 0.90$	marvelous / super
$0.80 \leq KMO < 0.90$	meritorious /great
$0.70 \leq KMO < 0.80$	middling /good
$0.60 \leq KMO < 0.70$	mediocre
$0.50 \leq KMO < 0.60$	miserable
$KMO < 0.50$	unacceptable

Source: own processing

Simultaneously with KMO statistics, we can use Bartlet´s test of sphericity, where the null hypothesis states that the sample correlation matrix is a unit matris. The statistics test is given by the relation $\chi^2 \frac{11+2p-6n}{6} \ln|R|$. If the null hypothesis holds, the statistics test asymptotically follows a distribution $\chi^2 \left(p \frac{p-1}{2} \right)$. The null hypothesis is rejected at the asymptotic significance level α if $\chi^2 \geq \chi^2_{1-\alpha} \left(p \frac{p-1}{2} \right)$. If the null hypothesis is not rejected, factor analysis is not suitable.

3 Results and discussion

We obtained initial information about the correlation structure of the data set from the implementation of a sample correlation matrix, in which 12 evaluated variables are included (tab. 2).

Table 2. Correlation matrix

Var.	F1	F2	F3	F4	F5	F6	F7	F8	F9	F10	F11	F12

Notes: F1 – human resources; F2 – attractive research system; F3 – digitalisation; F4 – finance and support; F5 – firm investment; F6 – use of information technologies; F7 – innovators; F8 – linkages; F9 – intellectual assets; F10 – employment impacts; F11 – sales impacts; F12 – environmental sustainability

Source: own processing using IBM SPSS Statistics 26

As we can see the correlations range from 0.146 to 0.873. To assess whether it is appropriate to implement a factor analysis on a given data set, the KMO statistics was used (tab. 3).

Table 3. KMO and Bartlett´s test of sphericity

Kaiser-Mayer-Olkin Measure of Sampling Adequancy		0.799
Bartlett´s Test of Sphericity	Approx. Chi-Square	400.234
	Df	66
	Sig.	0.000

Source: own processing using IBM SPSS Statistics 26

The value of KMO statistics is 0.799, so the implementation of the factor analysis appears to be good. The value of Bartlett´s test of sphericity is 400.234 and the number of degrees of freedom is 66. P-value is very close to zero, that is, the null hypothesis (the sample correlation matrix by the 12 considered variables is unitary) is rejected at the asymptotic level of significance 0.05.

The table 4 presents the initial eigenvalues and the percentage of variance explained. The first component

Table 4. Initial Eigenvalues

Component	Total	Cumulative Total	% of Variance	Cumulative %
1	7.192	7.192	59.932	59.932
2	1.410	8.602	11.751	71.683
3	1.096	9.698	9.137	80.820
4	0.640	10.338	5.332	86.151
5	0.471	10.809	3.926	90.077
6	0.362	11.171	3.016	93.093
7	0.278	11.449	2.320	95.413
8	0.202	11.651	1.680	97.093
9	0.145	11.796	1.210	98.303
10	0.093	11.889	0.773	99.076
11	0.069	11.958	0.575	99.651
12	0.042	12.000	0.349	100.000

Source: own processing using IBM SPSS Statistics 26

The first component explains 59.932% of the variability contained in the twelve observed variables, the second component explain 11.751% of the variability, the third component explain 9.137% of the variability, etc. (figure 2).
Figure 2. Eigenvalues – Scree Plot

Source: own processing using IBM SPSS Statistics 26

Based on the scree plot and the explained variance, three common factors were chosen. The total percentage of variability explained by the first three components is 80.820%. The Principal Component Analysis was applied for factor extraction.

Table 5. Component Matrix – 3 components extracted

	Component		
	1	**2**	**3**
Human resources	0.913	-0.041	-0.098
Attractive research system	0.901	-0.090	0.043
Digitalisation	0.757	-0.562	-0.177
Finance and support	0.820	0.007	-0.032
Firm investments	0.655	0.658	0.022
Use of information technologies	0.843	-0.376	-0.023
Innovators	0.585	-0.112	0.651
Linkages	0.902	-0.088	0.235
Intellectual assets	0.821	0.067	-0.275
Employment impactc	0.758	0.305	0.433
Sales impacts	0.580	0.616	-0.317
Environmental sustainability	0.649	-0.116	-0.456

Source: own processing using IBM SPSS Statistics 26

Then the factors were rotated using the rotation method called Varimax method with Kaiser Normalization (rotation converged in 5 iterations). Table 6 contains a variable´s

communality that is a useful measure for predicting the variable´s value. Communality is the total amount of variance a variable share with all factors.

Table 6. Rotated Component Matrix

	Component		
	1	**2**	**3**
Human resources	0.724	0.384	0.415
Attractive research system	0.681	0.499	0.331
Digitalisation	0.925	0.244	-0.077
Finance and support	0.603	0.392	0.395
Firm investments	0.114	0.345	0.855
Use of information technologies	0.820	0.417	0.079
Innovators	0.197	0.860	0.006
Linkages	0.595	0.665	0.282
Intellectual assets	0.678	0.183	0.510
Employment impactc	0.194	0.756	0.497
Sales impacts	0.231	0.016	0.873
Environmental sustainability	0.731	-0.058	0.323

Source: own processing using IBM SPSS Statistics 26

For example, the communality estimate of the variable „human resources" is 0.415, which means that 41.5% of variability of the variable „human resources" can be explained by the action of three common factors.

The plot below (figure 3) shows the variables in the rotated component space. It shows how the variables are organized in the common factor space.
Figure 3. Component Plot in Rotated Space

Source: own processing using IBM SPSS Statistics 26

4 Conclusion

One of the key attributes of a competitive economy is the ability to innovate. In an effort to benefit from strengths and strengthen areas where there are weaknesses, it is necessary to monitor the factors influencing the innovation performance of countries. There are several ways how to measure innovation performance. This research was focused on analysis of Summar innovation index (SII), that is a composite index annually published by the European Union within an Innovation Union Scoreboard (a tool to measure the innovation performance of EU member states). The main purpose of the article was to analyse the main areas of Summary Innovation Index (human resources, attractive research system, digitalisation, finance and support, firm investments, use of information technologies, innovators, linkages, intellectual assets, employment impacts, sales impacts, environmental sustainability) that affect the final SII value and to find out whether it is possible to define a smaller number of factors influencing the SII value based on their mutual correlation. To achieve the purpose of the article the factor analysis was applied. The appropriateness of applying factor analysis was confirmed by KMO statistics and Bartlett´s test of sphericity. By implementing principal component analysis, three main factors were identified that explain 80.820% of variability.

Comparison of speed creating of raster map tiles

Jakub Jech[1,*], and *Zdeněk* Červenka[1]

[1] Population Protection Institute, Directorate General of Fire Rescue Service of the Czech Republic, Na Lužci 214, 533 41 Lázně Bohdaneč, Czech Republic

Abstract

Research background: One of the most used part of any information systems could be any kind of a map viewer. From a global to local information systems, many of them have used map services with their requirements. The most important requirements for map services and maps themselves are accuracy and actual data. High accuracy and actual data are parameters of maps, which bring along a requirement for high capacity of storage, high network data throughput, and powerful hardware to processing data, etc. Therefore, to focus on these requirements, we compare speed of creating raster map tiles with high precision in this paper.
Purpose of the article: The aim of this paper is to compare the methods and processes for creating raster map tiles of the Czech Republic for the purpose of the Fire Rescue Service, and to propose solution on how to reduce the time needed for their creation. The whole process of creating raster map tiles is applied from central data store (CDS).
Methods: To create a complex map with all important information, it is necessary to have suitable source data, method or process of map creation, and powerful hardware.
Findings & Value added: The paper compares approaches of creating raster map tiles, and especially compares processing time and speed of creating tiles. The output approach proposes help to faster creation of a raster map tiles in the modern globalized world.

1 Introduction

One group of today's global needs are Maps (road maps, orthophoto maps, historical maps, urbanism maps) (Laurance and Balmford, 2013). Nowadays, precious and updated maps are required. Input data for maps are quite easily available, depends on providers and their pricing. In addition, the map creating is a process, which demands many recourses.

---

* Corresponding author: jakub.jech@ioolb.izscr.cz

Today's globalized world brings great benefits in obtaining, ascertaining, and sharing data or information. Those data or information can be used separately, or as an input for creating maps.

The process of creating maps has a long history and corresponds with cartography. Firstly, it is very important to define the purpose of a map, meaning what information the map brings to a map viewer or user, e.g. street net map, orthophoto map, etc (Brumarova et al., 2020).

Development of computer technology brings many advantages for the creation of maps. One direction in the development of computer technology was the creation of information systems. There is one specific way for managing geographic data in information system. Such direction is referred to as GIS - Geographic Information System (Clarke, 1999). Modern technology allows to share and show geographical data in many different ways. (Skopeliti and Stamou, 2019). GIS provides a lot of opportunities for countless institutions, scientist, services, etc.

Globalized world with all its possibilities opened a new way for using GIS. GIS analysis originated the trend of publishing many interesting studies (Werther et al., 2021), (Andreev, 2020), (Špica, 2021). Those studies are applied to the exististing and complex datasets. The datasets contain many information and viewers work with the existing map models or projects. A Map project is a basemap, which contains a big scale of information. Map projects or basemaps are defined by possibilities of showing a detail. The detail is called spatial resolution and interprets how many real world meters respond to 1 pixel of a digital map. A basemap can combine raster and vector data, but for high quality basemaps it is better to use only vector data (Netek et al., 2020). Basemaps created only by vector data look better in every detail with sharp lines; this is define by using vector data. This approach is more hardware intensive. Therefore, it is good choice to cache a basemap base on vector data into raster map tiles. Raster map tiles make up a grid, mostly a square grid, which changes for each scale level. The grid, which shows of a different scale level is called pyramid scheme. The Pyramid schemes are used to improve a display performance. They are a downsampled version of the original raster dataset and can contain many downsampled layers. Each successive layer of the pyramid is downsampled at a scale of 2:1, see Figure 6 (ESRI, 2022).

2 Methodology

The aim of this paper is to compare methods and processes for creating raster map tiles of the Czech Republic for Fire Rescue Service (FRS CR), and propose a solution of how to

reduce the creation time. The whole process of creating raster map tiles is implemented in a data warehouse (CDS) (CDS).

There are a few options how to browse maps, especially online maps. Google Maps is the most frequently used map service. It has a respectable speed of loading maps (Li et al., 2020). The Czech Republic has its own map service called "Mapy Seznam" (Seznam, 2022). But for the FRS CR needs, the CDS and GIS project group created their own map and map service (HZS ČR, 2022), (GISportal.cz, 2022).

The map project is formed by information layers, boundaries, scales, individual colour palette, etc. This paper is focused on the map project of the Czech Fire Rescue Service (FRS CR), which cooperates with neighbour countries. For this reason, the border of the Czech territory, called "*nuts0*" (ČSÚ, 2022), is extended to 20km away from the Czech border. The FRS CR used their own scales from 1:2 000 000 to 1:1 000, showing in the Table 11, and examples in Figure 7 and Figure 8. The main part of the FRS map project are input data layers. The data layers were obtained from spatial data suppliers, and for the map project data from 11 suppliers are used, which contain altogether 150 layers of spatial information. The map project use all three kind of vector type geo-features (point, line, and polygon).

Table 11. Table of FRS scales

Level of scale	Scale	Showing detail
L00	1:2 000 000	Country
L01	1:1 000 000	Region
L02	1:500 000	County
L03	1:200 000	District
L04	1:100 000	Metropolitan area
L05	1:50 000	City
L06	1:20 000	City district

Source: author (2022)

The data are stored on the servers in the Central data store (CDS) using multiuser geo-database PostgreSQL (actual in version 12). The database is connected via 1 Gbps full-duplex link with the corporate network. To transfer data layers or layer packages through the

corporate network is very fast. Raster map tiles were historically cached on the server. Such approach used to take a considerable amount of time (approximately 1 month) to process a less complex map project into 11 map display levels. With the increased content of information in the data layers, the creation of the map project was switched over on local PCs. Another reason was to lighten the load on the server. The structure of created folders has been original since the first caching and it is based on pyramid scheme for map tiles. Each level responds to a level of pyramid scheme and its exponential growing, see Table 12.

Table 12. Pyramid scheme of tiles

Level of scale	Scale	Count of tiles	
		256x256 tile size [px]	512x512 tile size [px]
L00	1:2 000 000	1	2
L01	1:1 000 000	1	2
L02	1:500 000	1	2
L03	1:200 000	4	2
L04	1:100 000	4	4
L05	1:50 000	4	4
L06	1:20 000	8	4
L07	1:10 000	28	9
L08	1:5 000	104	30
L09	1:2 000	620	150
L10	1:1 000	2340	600

Source: author (2022)

As the number of generated tiles increases, so does the size of each folder level, see Table 13. Total size of map project is 169 GB for tile size 512 by 512 pixel, resolution 96 dpi, and setup to 85 compression.

Table 13. Size of level folders

Level of scale	Size
L00	324 KB
L01	1,28 MB

L05	228 MB
L06	1,15 GB
L07	3,35 GB
L08	9,36 GB
L09	38,4 GB
L10	117 GB

Source: author (2022)

Processing requires many resources, both overall time and especially processing time, By using local high powered PC (8-core, 32 GB RAM, 1TB SSD), the caching process time on PCs was reduced was decreased from 1 month to 1 week (Ruan et al., 2021). Updating caching into new gaming PC (16-core, 64MB RAM, 2TB SSD) the processing time

decreased even more - to 5 and half days. Now comes the question: "Did we reach limit? And limit of what?" Limit of:

- Software
- Hardware
- Network – database access

The ArcGIS PRO is a 64bit software tool that is quiet "limitless". By monitoring task manager and performance usage, it was found that processor CPU usage was around 50%, memory usage around 20% and a solid state drive had a very high speed of writing and reading (Tripathy and Satpathy, 2022). For that reason, it was decided to make a copy of the database on a local cache machine.

3 Results

Moving whole tile caching process with all its requirements to a local machine was an optimal way. The entire tile process of map project includes powerful hardware, optimal software with local database access, and fast network connection. The gaming PC was used as a powerful hardware with configuration of 16-core processor, 64 GB RAM, fast storage to store data, and high-speed connections to deliver data. This computer contains gaming GPU, because some software tools are available to use for computing GPU. The used software equipment was: ArcGIS PRO (version 2.9.1) as a map tile processing tool, PostgreSQL (version 12) as an input data layers store, Windows 10 as an operating system.

Such combination of all key aspects led to an optimal processing of map tile caching. Hardware usage was on maximum and provided much better processing time. The whole process was reduced from almost one week to less than 1 day. Table 14 shows processing time for each scale level.

Table 14. Processing time according to scale levels

Level of scale	Count of tiles	Size	Processing time
L00	2	453 KB	0:01:00
L01	2	1,14 MB	0:01:00
L02	2	3,95 MB	0:01:00
L03	2	20,9 MB	0:01:00
L04	4	70,8 MB	0:03:00
L05	4	235 MB	0:10:00
L06	4	1,20 GB	0:29:00
L07	9	3,51 GB	0:24:00
L08	30	10 GB	1:08:00
L09	150	42,6 GB	5:35:00
L10	600	133 GB	14:36:00

Source: author (2022)

This processing is much efficient comparing to the use of a high-speed network shared database. Figure 9 shows a comparison of processing time for each level according to the processing entirely on a local equipment, and processing on a powerful machine with a network database.

Comparison of Proccessing time
Figure 9. Comparison of data processing

Source: author (2022)

4 Discussion

The decision to process the entire map project using a local machine with all its requirements brought many positives. The biggest positive was the significant reduction of the processing time of the map project, from 1 week to less than 22 hours. This processing configuration leads to an immediate response to correct errors in the map project or to update it.

The proposal for the optimal process of caching map tiles from a map project is to use a powerful local PC with a local database. This solution led to a significantly faster process of the map tiles. This solution has only one disadvantage, and that is the need to keep one extra database.

Spherical camera for creating 3D models

Jakub Jech[1,*], and *Jitka* Komárková[1]

[1] Institute of System Engineering and Informatics, Faculty of Economics and Administration, University of Pardubice, Studentská 95, Pardubice 532 10, Czechia

Abstract

Research background: Modern globalized world requires precious, verified, and photorealistic data. Utilization of 3D data belongs to contemporary trends in maps production. 3D image data acquisition and processing are resource intensive procedures. Drones can be used to collect suitable image data. This paper is focused on the collection of image data by means of a spherical camera mounted on a drone.
Purpose of the article: The aim of this paper is to propose a procedure how to process image data from a spherical camera mounted on a drone to a 3D model. The whole procedure is applied to data of a chosen building.
Methods: The paper compares approaches for data acquisition to the circular 360-degree method. Pix4D software was used to create digital surface model and generate point cloud. 3D cartographic methods to visualize results are used in the last step.
Findings & Value added: The paper shows the entire procedure leading to a 3D model based on 360-degree source data collected by a drone. The proposed procedure helps to create 3D models in the modern globalized world.

Keywords: *3D model, drone, spherical image data, DSM*

JEL Classification: *Y91; Z33; R59; R39; L86*

1 Introduction

Today's globalized world wants to have realistic model of everything - processing, physics-based, behaviour, etc. (Verma et al., 2011; Li, 2022; Manivasagam, 2022). A new trend has started in this millennium – a realistic and precious modelling of physical objects, especially 3D modelling. These models cover scale from small objects (e.g. statues) to big areas (e.g. cities).

With modern technologies and possibilities available thanks to the globalization, it is very easy to create own 3D model of physical object.

3D modelling has a lot of approaches how to create 3D model. First of all, the object of the modelling must be defined. Particularly, it must be clean if it is a single object or if it is

---

* Corresponding author: jakub.jech@upce.cz

an object with its surroundings. For single modelling, some CAD software or a model based of real images are usually used.

3D models have wide areas of application, from medical issues (Awori et al., 2021), forensics (Leipner et al., 2016), constructions (Adán et al., 2020), to GIS (Khayyal, 2022).

Modern approach is using spherical cameras for obtain an image for 3D models. Spherical camera is made by using a multiple lens, at least 2 with 180° angle of view. This approach of data acquisition is mostly used for creating 3D models (Barazzetti et al., 2022). Especially 3D models of interiors and randomly taken images (Barazzetti et al., 2018). For outside 3D models is better to use an UAV (Pepe and Costantino, 2021), (Karachaliou et al., 2019). These models are created by images from an UAV camera itself. New possibility of spherical cameras allow to get better input data. Combination spherical camera and an UAV brings new opportunity for 3D models, especially large outside 3D models (Calantropio et al., 2019), (Humpe, 2020).

2 Methodology

The aim of this paper is to propose a procedure how to process image data from a spherical camera mounted on a drone to a 3D model. By acquisition spherical image data, it is possible to modelling focused object with the surrounding area. The procedure will be designed that uses UAV planned flight with mounted spherical camera and meshing software methods are used for 3D model processing.

The drone or an UAV quickly capture the area of interest or object of interest. For high-quality and precious data acquisition, it's important to use a planned flight. Planned flight provide best results without necessary time delays or redundant image data. For scanning areas of interest or objects of interest for 3D models, there is exist 2 main approaches of planned flight. First one is double grid planned flight, see Figure 10, which is basically classic orthophoto scanning in two directions (Röder et al., 2017). Double grid planned flight usually use -90° pitch of camera gimbal. This setting can be used as input data for 3D model. But there can be missing parts of scanned object because perpendicular scanning cannot see object which is cover by different one from above. This approach is useful for scanning open areas or objects. For more complex or articulated objects is better use different gimbal angle, mostly -45°. This camera gimbal setting can see more objects hidden by different objects. But planned flight must be oriented to centre of object. Generally, this approach is better for bigger areas.
Figure 10. Double grid flight plan

Source: Pix4D (2022)

Second approach for 3d scanning is circular scanning. This approach is based on circular planned flight, which is directly focusing to object, see Figure 11.

Figure 11. Circular flight plan

Source: Pix4D (2022)

Also, for this approach exist more setups. Fastest setup is planned circular flight with only one setting of angle camera gimbal. This approach can be used for scanning object from a quite great distance, where gimbal pitch setting can cover a big part of scanned object. Better setup is flight in more flight levels with different gimbal angle setting, see Figure 12.
Figure 12. Positions for 3D scanning

Source: Dinosaurpalaeo (2022)

These two approaches are most used for classics scanning by an UAV. Modern possibility is used spherical 360-degree camera for 3D scanning. Big advantage of this spherical camera is angle of scanning. From the name of camera, the angle of scanning covers all directions, so it is scanning in 360° of view. For comparison, build-in camera in drones can cover up to 80° of view. This is quite modern approach of scanning object for 3D models.

This finding led to try new possible way of 3D scanning and that is using one level circular planned flight with spherical camera. This combination guarantees wide shooting angle for scanned object in only one planned flight path. Moreover, outputs from spherical camera allow to create more complex 3D model with more wider boundaries around scanned object. Comparison of angle of view: see Figure 13, it is image taken by drone camera. Figure 14 shows spherical image transferred to flat projection; red boundaries represent drone camera's view angle.

Figure 13. Drone camera angle of view

Source: Author (2022)

Figure 14. Spherical camera angle of view

Source: Author (2022)

The DJI Mavic 2 DUAL Enterprise (DJI, 2022) was used. This drone is a small size drone with 899 grams take-off weight and maximal take-off weight 1100 grams. For flight planning was used an iPad application Pix4D capture (Pix4D, 2022). This app is freeware and provides interactive flight planning in multiple ways and controlling planned flight itself. For collecting, prepare and align images was used Pix4Dmapper software (Pix4D, 2022). Pix4Dmapper is advanced photogrammetry software which provides a lot of functions, include build-up 3D models from an images or videos.

3 Results

The new approach of data acquisition provides very good quality of 3D model. For all calculation was used Pix4D software and output models were exported in triangle meshes. In Figure 16 and Figure 17, there is a comparison of new approach and circular shooting, both taken in one flight level. Because object of intertest was quite far away from drone flight plan, there was no need take more flight levels. The 3D model from circular planned flight is bad, there is missing parts of examined object. The 3D model build from spherical data is complex and contains wider area around object of interest. The detail is also different for both models, see Figure 15.

Figure 15. Detail comparison; left circular, right spherical

Source: Author (2022)

Figure 16. Output 3D model - circular approach

Source: Author (2022)

Figure 17. Output 3D model - spherical approach

Source: Author (2022)

4 Discussion and Conclusion

As already mentioned, using circular planned flight with spherical camera is very useful combination as input data for 3D models. This approach is very suitable for fast data acquisition for 3D models.

There is one limitation of this approach: a loss of spatial information when is using 360-degree video as an input for 3D models. It is important to address this issue when it is planned to use 3D models together with spatial data and maps. Solving this problem is using georeferencing, that 3D model is registered to real world object with spatial coordinates, when it is showed in GIS software.

Simulation model in project management planning: case study

Pavel Juřica[1,*], and *Vladimír* Bartošek[1]

[1] Brno University of Technology, Faculty of Business and Management, Czech Republic

Abstract

Research background: The field of project management as well as the main world standards and methodologies of project management is divided into classic approaches and agile approaches. Beyond these two approaches a number of recognized authors mention and present a third way out which is created by a mutual combination of these two (classical and iterative (or agile)) approaches. The current question of today is the possibilities and approaches of digitization of both two (or three) approaches that the present time or all stakeholders of each project are increasingly demanding.

Purpose of the article: This article focuses on and compares the possibilities of digitization of planning and management of selected project representative. The presented contribution shows the importance of using digitization in project management. Supplementing the existing approaches with modelling and simulation of the project process itself can bring another dimension to project planning.

Methods: The basic research methods used are a qualitative form of research, through observation, comparison, analysis of text and documents, which are supplemented by the so-called basic scientific methods (i. e. modelling, simulation etc.). Our approach was verified on a specific construction project.

Findings & Value added: The results on the example of a real project show that the usage of simulation during the project planning phase can point out possible issues during project management and increases the probability of project success. Thus, our approach supports the achievement of the value expected from the project by stakeholders.

Keywords: *project management; digitalization; simulation; planning*

JEL Classification: *M11; M15; M16; M21; O32*

1 Introduction

The whole of human history is connected with many historical milestones, buildings or achievements, as evidence or examples of project management and its connection with

---

[*] Corresponding author: pavel.jurica@vut.cz

business management. Project management is a relatively new, dynamically developing discipline, with practically the first complete mentions of project management appearing in the second half of the 20th century.

Tools and techniques are used within project management processes. This article is focused on the project planning process, in which we can give examples of work breakdown structure (WBS), gantt chart and network diagrams. The use and mutual combination of these basic management approaches is supported and developed by a number of software products.

In the advanced layer of project management today, there is a reflection, of the current needs of linking, sharing, coordination, analysis and presentation of both individual tasks, but especially a comprehensive effort to unify technical documentation from the preparatory stage (e.g. at the CAD level) to the implementation and final stage of each project.

The use of simulation is recommended already in the project definition phase, as it facilitates the delivery of the value expected by interested parties (Mrzygłocka-chojnacka et al., 2021).

The following article focuses on and compares the possibilities of digitizing project planning and management. The contribution shows the importance of using digitization in project management, when supplementing existing approaches with modelling and simulation of the project process itself, can bring another dimension of results or benefits. The existing static view of the project plan is supplemented with a time dimension and adds new possibilities.

We are aware of the limitations that this approach brings in different types of projects and in today's different approaches to project management (agile, waterfall, hybrid).

2 Literature review

As stated by (Agbejule and Lehtineva, 2022), traditional project management emphasizes disciplined methods of planning and control and brings formality to project management. The traditional schedule-driven approach is most effective in projects with stable and well-known requirements. On the other hand, this approach usually faces challenges in projects with a high degree of uncertainty. Simulation can also be used for project management techniques in an agile environment, but only at the level of sub-situations (Damij and Damij, 2021). If the condition of accurately specifying the project goal is not met, the only option is to proceed in an agile way (Vanzant, 2020). Many authors have been dealing with the combination (so-called hybrid) model of project management recently, while a systematic view (Reiff and Schlegel, 2022) presents not only their direct definition, but especially the method of their combination.

Dynamic simulation techniques have shown to be a flexible method for modelling the dynamic complexity and the associated risks of the projects. In the context of dynamics and feedback loops, the application of control measures taken by the project managers can increase the reliability of the change management decisions (Shafieezadeh et al., 2020).

Some authors also point to the fact that a form of scenario simulation can be a useful way of supporting skill development (Salminen-tuomaala and Koskela, 2020) or (Tarpey, 2022). In the area of building demolition, there were simulations finding out inappropriate sequences in schedule, conducting evaluation of issues related to constructability, and identifying disagreements in time and space. The proposed guideline could help identify errors in construction scheduling, which have the potential to reduce project cost and duration (Alzarrad et al., 2021).

The study (Ying et al., 2021) evaluates the importance of the supply of material to a construction project as one of the important elements of construction operations and an important factor influencing the quality of construction projects. In fact, they refer to logistics

processes as supporting and indicate the potential of developing control of these processes through simulations. There is a need to postpone possible preparatory work away from a construction site (Choi et al., 2022).

Although the existing approaches of some software products are aimed at achieving a 4D view of the project, including the necessary interconnection, it is becoming increasingly clear that modeling or simulation must be involved in both the preparatory part of the project and the operative level.

3 Methodology

The aim of this research was to verify the appropriateness of using modelling and simulation of the project process for a specific project.

The added value of the contribution is in the area of the selected project type, the compilation of a simplified WBS of the first level necessary for the sequence of the chronology of the project plan, which leads to the orientation and achievement of the value expected from the project by the stakeholders.

Research of secondary information sources, modelling and simulation methods were used in the creation of the paper. The basic research methods used are a qualitative form of research, through observation, comparison, analysis of text and documents, which are supplemented by the so-called basic scientific pair methods.

Project management tools based on IPMA and PMBoK international standards were used for the project plan. These are WBS, Gantt chart, Network diagram tools. Processing was implemented with software support. MS Project was used for the project plan. Visualization in SkatchUp and the simulation itself in 4D virtual builder.

The main limitation of the research process is determined by the chosen typology of the project, but at the same time it is based on the research methodology used. None of the international standards of project management (PRINCE2, PMBoK, ICB) use any classification point of view enabling the categorization of individual types of projects (Axelos 2017), (PMI, 2021) and (IPMA, 2015). We cannot forget the limitations related to the professional focus of the authors, when it would be necessary to assemble a multi-member interdisciplinary research team of international composition. Similarly, last but not least, orientation towards English literature or authors publishing in the English language can be perceived as a limiting level of the contribution and research results.

3.1 Presentation of the project solution

We focused on a traditional/waterfall approach to project management. In it, the goal is fixed at the very beginning of the project and should ideally be unchanged until its completion. Based on this definition, it is clear that simulating a variable project would be practically impossible. Due to the availability of documentation, a construction engineering project from the field of building construction was selected. These projects use classic tools in project planning and it was therefore possible to supplement them with the subject of our research (simulation).

In particular, it was about the visualization of the building over time. This visualization is created to better understand the project plan and individual deliverables in the timeline. Last but not least, also as a basis for a presentation for the project's main stakeholders and the implementation team.

Research Questions:
What unpredictable situations will the simulation show us?
What is the point of using simulation in project planning?

The progress of the project as a basis for the processing of the plan, understand work packages, continuity and determining the duration.

The tasks in the project are divided into several main groups of outputs. These are: Bypass route, Land transportation. There are also three separate tasks for which it was not necessary to model (Preparation, Quality Tests and Construction Handover) and start and end milestones. For clarity, a WBS of the first level was created, which was further worked with.
Figure 1. Work breakdown structure.

Source: own processing

3.2 Task chronology

Specification of the main structural systems, the sequence of activities and technologies and the method of their supplier availability. Their progress is based on technological procedures and best practices from previous implementations. Specification of the main construction machines and mechanisms. Determination of the basic concept of construction site operation, its connection to surrounding roads and energy sources. Establishing principles for ensuring work quality and quality control, including environmental protection and work safety conditions.

The duration of construction works is determined mainly on the basis of the performance of machines or workers. For each machine, it is known how much power it has and how much time it needs can be calculated. Management assigns a time reserve to each task. The company thereby protects itself against contractual fines for time delays, and since the investor checks the timely completion of each task, there is a reserve for each of them.

The project starts with the first output called preparation. The first activity here is measurements, prices, other documents. This part is processed by the preparer. From the available technical documentation, he/she calculates the necessary amount of material for which he/she announces a tender. Subsequently, the competition for suppliers of material takes place. Duration is one week. The output of this task is the selected supplier. The logical next step is to draw up a contract for the supply of material, which takes one day. The last task of preparation is the equipment of the construction site. It is mainly a background for construction workers. This activity takes one day and can be done at any time during the entire preparation package. The entire preparation output does not need to be modelled at the activity level and in our system represents a time span of ten days.

The following outputs are of a professional and technical nature and relate to the construction process. Here they are listed briefly, without details.

The second output of the project is the bypass route. It contains only one activity, and that is Milling and straightening the cover of the bypass route. 4 days are reserved for this.

The main output of the project is roads. these are grading (earthworks), design of the earth body, building materials for the construction of transport structures, structural layers. It starts with site preparation, marking bypass routes, which will be done in two days. The successor is work on the soil removal. Namely: removal of topsoil - excavation work on the culvert and

repair of the culvert and reconstruction of the inlet. Six and eleven days are set aside for these activities. The package continues with milling the asphalt cover, which has five days to spare. Followed by local repairs of broken cover, with the same duration. The laying of new asphalt layers takes four days to complete. The roadside reconstruction will take two days. Traffic markings are implemented within two days. The package ends the activity cleaning the construction site, which will be carried out in one day.

Quality tests are a separate activity.

The last task is the handover of the building, which will take place within one day. Its contents include running errands after the construction and writing the protocol. Everything ends with a milestone, which is also specified in the contract, from which contractual fines for non-compliance with the work contract start.

The Figure 2 gives a preview of the Gantt chart in MS Project.

4 Results and discussion

As part of the research, theoretical insights from project planning organization (Igberaese, 2022) and (Vanzant, 2020) were applied. The verification took place on the reconstruction plan of the selected road. Modelling and simulation in Microsoft Project software in combination with 4D Virtual Builder was used. SkatchUp software was used as a resource for processing graphic outputs.

4D Virtual Builder is a powerful modelling plugin for SketchUp that allows you to create complex and large-scale graphic projects and designs. Simulation includes the ability to visualize models based on a timeline and visualize changes being made in real time. In our case, the finished visualization also represents a connection with other logistical topics such as space limitation, space arrangement and necessary input-output material flows, or Illustrations documenting their size and intensity.

The simulation created in the 4D Virtual Builder program connected the time schedule from the Gantt diagram and the 3D model of the solved civil communication created in SketchUp. The applicability of this simulation is shown mainly when carrying out construction work in a small area. When the plot designated as the background of the building is small, there is a need to plan the use of the space over time. This means arrivals of materials and its schedule, space location (storage) of machines and more. This is where the simulation of the project model used by us stands out. In this way, the probability of additional change management costs is reduced. Additional costs can then arise from time delays tied, for example, to contractual fines.

Every competitive advantage of a construction company can bring new customers. The change in the planning area will also contribute to limiting the release during the project implementation itself. Therefore, the costs of implementation will be reduced and with them, better results of the company's management can be expected. Other factors such as job security, the possibility of risk management, etc.

The minimization of undesirable situations and savings related to the solution of change management (or crisis situations) has a multiplicative nature (i.e. when used on a larger number of buildings (projects), their multiplication occurs). This finding was clearly confirmed in the investigated company, where the company's historical data showed a similar solution to the situation, which could have been detected in advance by simulation and occurs in 20% of cases. If the company were to use the simulation, in the long run, the introduction of the mentioned method of project modelling and simulation would pay off.

It would be possible to supplement our simulations with virtual reality, which, however, has additional limitations (Boton, 2018). A possible future of project planning is also in artificial intelligence (Salem and Dragomir, 2022).

5 Conclusion

Current modern approaches for the creation and management of construction projects based on the existing planning model enable the design and management of ground infrastructure through connection to CAD tools, beyond the scope of project management. In this way, the required BIM (Building Information Modelling) methodology is being implemented both at the European (for example: Commission decision of 28 November 2011 setting up the European multi-stakeholder platform on ICT standardization) and at the national level. It will bring the cooperation of a whole range of solving entities and their cooperation in real time on the model of a large whole to which sub-projects contribute. This fact is similarly mentioned by (Vilutiene et al., 2019) and (Martinsuo and Geraldi, 2020).

Building Information Modelling forms the beginning of a sequence of real-time (4D) project management steps; (5D, costs) and (6D, the so-called life cycle of the building), which indicates its wide range of uses. On the other hand, the mere fact that not every structure is a building is a fact that will always limit the use of standard Building Information Modelling approaches.

Similarly, the case study proved that the project planning stage often contains a number of related (secondary) issues that may not be directly related to the project, but their effective resolution becomes a necessity in a wide range of industries.

The main knowledge and findings show that while the pace of digitization of planning and management by classical approaches has progressed considerably to such an extent that a number of project management tools are already fully integrated in IS, a non-negligible dynamic development can be expected for the remaining two approaches. The result of the implementation of the spatial simulation surprisingly pointed out the need to also plan the use of space in time. Simulation should become part of the entire life cycle of the construction portfolio and not just one separate project.

Formation and development of the electric vehicle market in the global market

Alisher Yerkinuly Kabylda[1]*,* and *Mária* Urbánová[1,*]

[1] Slovak University of Agriculture in Nitra, Faculty of Economics and Management, Institute of Economics and Management, Trieda A. Hlinku 2, 949 76 Nitra, Slovakia

Abstract

Research background: There are two directions for the creation of electric vehicles: the first is the development of new models, the second is the adaptation of mass-produced cars. The second direction has become more widespread since it is less expensive. Various governments have developed strict CO2 emissions regulations that have increased the demand for electric vehicles and provide incentives and subsidies to boost sales of electric vehicles.

Purpose of the article: There is a gradual shift of the main interest from car makers to electric vehicles. The purpose is to show the formation and development of the electric vehicle market, analyse current volume of produced vehicle, and observe planned targets of vehicle producers in international market and research investments budgeted.

Methods: The characteristics of electric vehicles will be explained followed by the study of the international sales by well-known companies, and considered forecasts made based on STEPS and APS scenarios. The investments allocated by different vehicle manufacturers for the next decade would be analysed and concluded the expected investment forecasts in the Chinese market.

Findings & Value added: Different countries use their own charging standards and big problem is that several charging stations can only be compatible with a certain type of voltage. The growth in sales of electric cars will increase the demand for electric filling stations in the world and given the fact that they are already in short supply in several countries, especially where the number of electric car owners is high, this could become big problem.

Keywords: *development; electric; vehicle; global; comparative*

1 Introduction

The global pandemic has been a huge stress test not only for companies, but for humanity. The crisis has shown which companies can take care of their employees even with reduced or zero income. Sewing workshops stopped sewing covers for car seats and readjusted machines to cotton masks, disinfection was produced by companies that do not deal with this field at all. The bonding was huge and showed the need for Social Responsibility. Just as people cannot think only about their needs, companies must behave in the same responsible way. Authors of review on Electric Vehicles: Technologies and Challenges. Smart cities, Sanguesa et al. (2021) describes an electric vehicle as a vehicle that is powered by one or more electric motors. The electric motor can be powered either from a battery or solar battery, or from fuel cells and also determines that most of the electric vehicles in use are battery-powered designs.

Richardson (2013) emphasizes that there are two directions for the creation of electric vehicles: the first is the development of new models, the second is the adaptation of mass-produced cars. The second direction has become more widespread since it is less expensive unlike a car with an internal combustion engine, an electric car has a simpler design, which has a minimum number of moving parts, which has a positive effect on its reliability.

Based on extreme fast charging of electric vehicles a technology overview shows that the main building blocks of an electric vehicle are battery, electric motor, transmission, on-board charger, inverter, DC-DC converter, and electronic control system. The battery is designed to provide power to the electric motor. The most widely used lithium-ion battery, which is a series of modules connected in series. At the output of the battery, a DC voltage of about 300V is removed. The capacity of the battery must match the power of the electric motor.

Tu et al. (2019) noted that an electric motor is also one of the main elements of an electric vehicle. It is designed to create the torque necessary for the movement of the machine. We observe that a traction motor, three-phase synchronous (asynchronous) AC motors with a power of 15 to 200 or more kW are used. Compared with the internal combustion engine, the electric motor has high efficiency and less energy loss. For example, the efficiency of an electric motor is 90%, while that of an internal combustion engine is only 25%.

Based on Christensen (1997) study, some electric vehicle designs use multiple electric motors to drive the individual wheels of the vehicle, greatly increasing its propulsion power. There is also a design where the electric motor is installed directly into the wheel of the car, reducing the transmission to a minimum. But such a scheme has a serious drawback - the unsprang mass increases and the handling deteriorates. In his research Mousavi et al., (2015) describes that the transmission of an electric vehicle has a fairly simple design and, on most models, is a single-stage gear reducer and demonstrate that an on-board charger is required to charge the battery of an electric vehicle from a household electrical outlet. Solution of car producers and research studied by Poorfakhraei (2021) affirms that the inverter is used to convert the high DC voltage of the battery into the three-phase AC voltage needed to run the electric motor. The DC converter is designed to charge an additional 12V battery, which is used to power such consumers of the car's electric power as electric power steering, air conditioning, lighting system, windshield wipers, multimedia system and others.

Technical passports of electric vehicles demonstrate that an input sensor is used to evaluate the position of the gas and brake pedals, the gear selector, and the pressure in the brake system and the state of charge of the battery.

2 Methodology

The main characteristics of electric vehicles will be clarified at first. Next step would be the analyses of the international sales by well-known companies.

Recent studies according to Cuma and Koroglu (2016) show that the research of estimation strategies is one of the main interests in the field of electric vehicles as well as battery technologies, vehicle control, charging and grid interaction issues. Estimation of any fault, state or information plays an important role in ensuring vehicle stability and reliability.

Forecasts in the article are made based on STEPS and APS scenarios which are exploratory. They define a set of policies and targets, and then forecast based on model representations of energy systems, containing market dynamics and technological progress. The latter implies the intensification of policies to limit emissions (including regulatory restrictions), large-scale investments in the creation of infrastructure at a faster pace, as well as stimulation of the purchase of electric vehicles.

The Stated Policies Scenario (STEPS) is the baseline scenario of the IEA flagship reports. This scenario mirrors all existing policies which have been implemented or announced by governments around the world.

It includes current electric vehicle related policies and regulations, as well as the expected effects of announced deployments and plans from industry stakeholders. STEPS aims to hold up a mirror to the plans of policy makers and illustrate their consequences. The Announced Pledges Scenario (APS) appears for the first time in the WEO-2021. The version published in the WEO-2021 takes account of all of the climate commitments made by governments around the world up to early October 2021, (IEA, 2021).

BEVs mentioned in the article stands for a battery electric vehicles. PHEVs are plug-in hybrid electric vehicles. FCEVs are fuel cell electric vehicles. EVs talk about to all electric vehicles (BEVs + PHEVs).

In the last part, the study of the investments allocated by different vehicle manufacturers for the next decade and comment on the expected investment forecasts in the Chinese market will be made.

3 Results and discussion

The table 1 shows the main characteristics of electric vehicles. As can be seen from this table, electric vehicles are not inferior to traditional cars in terms of dynamic qualities, but in terms of energy efficiency, as shown, they are significantly superior. In terms of speed properties, an electric car is significantly inferior to traditional cars, but for urban conditions this is not a disadvantage.

In terms of sales volume, the electric vehicle market is closest to the tipping point. Data from ICCT briefing 2021 shows, that in 2020, sales of electric vehicles in the world amounted to 4.2% of the total volume of the global passenger transport market - 3.1 million vehicles. As stated in electricity market report (2022) expected institutional changes and technological breakthroughs in the global market will lead the industry to move from a market growth stage to a mass rapid transition stage in the coming years.

Table 1. Characteristics of electric vehicles

Electrovehicle	Weight	Engine power	Acceleration time to 100 km/h	Max. speed	Battery	Power reserve on full charge
Tesla Model X	-	567	3,8	250	90	400
Jaguar Land Rover "I-Pace"	2100 -	294	4,8	200	90 (Li-Ion)	480
Porshe Taycan	-	560 (1050)	2,8	260	93,4 (Li-Ion)	412
Nissan Leaf E	1525 - 1965	80 (280)	11,9	144	24 (Li-Ion)	175
Volvo Polestar 2	-	300	5	-	78 (Li-Ion)	500
Renault Fluence	1605 - 2025	70 (226)	13	135	22 (Li-Ion)	185
Renault Zoe	1390	60 (222)	-	135	(Li-Ion)	160
Roll-Royce	-	290 (800)	8	165	Li-NMC	200
Chevrolet Bolt	-	147 (360)	7,2	160	60 (Li-Ion)	380
BMW I3	-	125 (250)	-	-	42 (Li-Ion)	-
Mazda MX-30	-	107 (265)	-	-	35,5	200
Audi E-tron	-	265	6	200	95 (Li-Ion)	400
E Lada	1250 - 1610	60 (275)	14	130	17,3 (Li-Ion)	150

Source: own processing based on brand's official sources (2022)

In Global EV Outlook data (2021) based on STEPS, shown for publicity demonstrates that the electric vehicle market in the base case will reach sale of 15 million vehicles in 2025 and more than 25 million vehicles in 2030, which correspond to 10 and 15% of the total car market, respectively (Figure 1). The APS scenario assumes that in 2030 the level of global sales will reach 45 million units, which will be about 35% of the total market (Figure 2).
Figure 1. Sales of EV forecasts based on STEPS

Source: own processing based on iea.org (2021)

Investments by vehicle manufactures

We observed that United States electric car maker Tesla has opened a "Gigafactory 3" plant in China, near Shanghai. The construction of the company's plant took only one year. Currently, the plant assembles cars and about 30% of components, and the construction of the second production line was completed by 2021, which allowed to increase the percentage of components produced locally and expand the range of cars. It is not without reason that the company turned its attention to China. Technode analysts assess that despite 25% import duties, China remains Tesla's second largest market, trailing only the Unites States and ahead of Norway and the Netherlands. But in the United States, the period of state tax crediting for Tesla cars is coming to an end (Edmunds, 2022), which means that interest in them is likely to gradually fade. In China, certain laws were passed (Liu F. et al., 2020) that resulted in increased price of cars with internal combustion engines. This further spurred the demand for electric cars.
Figure 2. Sales of EV forecasts based on APS

Source: own processing based on iea.org (2021)

The German non-profit organization Center for Research on Solar Energy and Hydrogen Baden-Württemberg (Nieder and Püttner, 2020), states that sales of electric and hybrid vehicles in China reached 1.2 million in 2018, which is 61.8 of all electric vehicles sold in the world last year.

According to many experts, building a factory in China will allow Tesla to cut shipping costs and avoid import duties. The starting price for the Chinese-made sedan, which will be sold only in the local market, is approximately 328,000 yuan (White, 2022). Thus, an elite American brand will be able to compete even with manufacturers of cheap Chinese cars like BAIC Motor Corp. and BYD, which offer sedans for about 200,000 yuan.

Thanks to Chinese government support, the plant was built in record time. It took Tesla just 168 days (or about six months) to go from getting building permits to bringing electricity to a brand-new plant. The company has made a big bet on process automation: most of the plant area is occupied by hundreds of robots that are involved in almost all stages of production. However, the complete rejection of the human workforce is still far away, although Elon Musk seriously assures that over time, all Tesla enterprises will become completely autonomous, turning into "machines that make machines".

As we observed the Model 3 was the first car to be produced in a wholly foreign-owned factory in China. As of 2022, Model 3 weekly output has risen to 3,000 units, giving an annual production capacity of 150,000 vehicles. The next planned milestone is 250 thousand, while the Model Y crossover joined the sedan.

Reuters published an analytical study (Lienert and Chan, 2019) of the activities of 29 of the world's largest automakers. The study showed that the total investment in electric transport is more than $300 billion, with about 45% of these funds concentrated in China. In the next 10 years, world industry leaders intend to invest huge financial resources in the development of battery technologies and the development of electric vehicles in general. According to study forecasts, a significant part of these investments will be directed to the Chinese economy.

Table 2. Companies investing in Chinese market

Producer	Country	Investments (in U.S dollars, milliard)	Investments in batteries (in U.S dollars, milliard)	Investments in China (in U.S dollars, milliard)	Share of China
Volkswagen Group (Volkswagen/Audi/ Porsche)	Germany	91	57	45,4	50%
Daimler (Mercedes/ Smart)	Germany	42	30	21,95	52%

Mazda	Japan	0,25	–	–	–
Overall investments in China				135,56	

Source: own processing based on iea.org and reuters.com (2022)

Based on annual car producer reports, in a sum, China will receive 135 billion dollars. The country is actively promoting the production and sale of electric vehicles through a system of government-approved quotas, loans, and incentives. As a result, spending by major Chinese automakers such as SAIC and Great Wall Motors can be equal to, and in some cases even less than, their foreign counterparts such as Volkswagen, Daimler, and General Motors. Reuters (2019) analysed the investment budgets released over the past two years by automakers from the US, China, Japan, South Korea, India, Germany, and France.

The study does not include the amount of associated costs incurred by auto parts suppliers, technology companies and large corporations in industries ranging from energy and aerospace to electronics and telecommunications.

Daimler plans to introduce 130 electrified vehicles by 2030, including hybrids and fuel cell models, and has budgeted about $30 billion for batteries. The entire range of the Smart brand consisted exclusively of electric vehicles by 2020, while Daimler will expand its product line with electric vans and heavy-duty trucks. The company is investing $1.9 billion in the Chinese economy through cooperation with BAIC. Negotiations are also underway with the Chinese firm BJEV to launch the production of Smart electric vehicles in China.

Hyundai and its subsidiary Kia reported that they will invest $20 billion over the next 3 years in electric and self-driving vehicles. By 2025, it is planned to produce 14 electric cars, 12 hybrids and 2 fuel cell vehicles. The group is also investing $6.7 billion in the development of hydrogen engines.

Toyota affirmed their plans of $13.5 billion investments in battery technology by 2030. Together with Mazda and Denso, the company owns enterprises involved in the development and production of electric vehicles. Also, Toyota plans to produce 10 new electric vehicles in China by 2023, and by 2025 to introduce electrified versions of all existing models. It is expected that by 2030, 5.5 million electric vehicles of this brand will be sold worldwide.

Ford Team Edison Product Development Director stated that Ford plans to launch production of 24 new hybrid models and 16 electric vehicles by 2022. According to the company publications, by 2025, 70% of the brand's vehicles made in China will run on electricity. The cost of the joint venture between Ford and Zotye, which produces electric vehicles in China, is estimated at $750 million.

The Renault-Nissan alliance's R&D emphasized their budget of $20 billion. The group plans to launch 17 electric vehicles, including 8 new Nissan-branded electric vehicles. In addition, Nissan is investing $9 billion with Dongfeng to manufacture 20 electric vehicle models in China. Another $335 million will be invested in the construction and launch of a battery cell plant in Thailand.

GM plans the launch of 23 new electric cars by 2023, and by 2025 will introduce electrified versions of almost all Chevrolet, Buick and Cadillac models sold in China. GM, together with SAIC, will be engaged in the production of battery cells for electric vehicles in China. Based on report, the American automaker is also investing in new design solutions for electric vehicles and battery systems. However, according to company representatives, over the next few years, the amount of capital investments in electrification and automation will be only $ 8 billion.

BMW asserted their plans to introduce 12 new electric vehicles and 13 hybrids. The company is investing $340 million to build a plant in Leipzig and another $225 million to launch battery production in Munich. In addition, BMW will invest $700 million in a joint venture with Chinese automaker Great Wall.

Figure 2. Visual share of investments in China by brands

Source: own elaboration based on iea.org (2022)

4 Conclusion

Various governments have developed strict CO2 emissions regulations that have increased the demand for electric vehicles. In addition, governments provide incentives and subsidies to boost sales of electric vehicles.

Different countries use their own charging standards. At the same time, a big problem is that several charging stations can only be compatible with a certain type of voltage. As mentioned earlier, the growth in sales of electric cars will increase the demand for electric filling stations in the world and given the fact that they are already in short supply in several countries, especially where the number of electric car owners is high, this could become a big problem soon the future.

It is impossible to speak in full about the fact that electric vehicles can solve the environmental problem, because. They have different impacts on the environment. On the one hand, there is a reduction in CO2 emissions, but on the other hand, at present, in many countries there are no regulations governing the process of recycling and disposal of batteries.

Those lobbying for the idea that electric vehicles will reduce dependence on traditional energy sources, which in turn will improve the energy security of developed countries, are

also not entirely correct in their statements. Yes, dependence on traditional sources (oil, gas, etc.) will decrease, but dependence on rarer sources of raw materials (lithium, cobalt) used in the manufacture of batteries will increase.

By 2025, this number will be 25,000,000 per year. By the same year, electric vehicles will account for 20-22% of all cars. The major carmakers are far behind Tesla and Chinese manufacturers in terms of innovation in the electric car market, but they have serious intentions regarding it. Thus, Volkswagen, which sold 8,000 electric cars (including hybrid ones) in China, sold 400,000 such cars in 2020, and by 2025 it will sell 1,500,000 units a year.

Experience shows, however, that forecasts rarely go unadjusted, especially in the face of uncertainty in which we live today. On the one hand, market developments may encourage other carbon-neutral countries to adopt similar targets, to reduce emissions from transport, which is problematic to decarbonize. On the other hand, a massive transition to the production of electric vehicles can provoke an increase in the cost of batteries (according to one of the world's leading investment banks, by an average of 18%), whose share is estimated at 20-40% of the total production costs for an electric car. Such a jump threatens to slow down the growth in demand for electric vehicles.

The Impact of Globalization on the Slovak Electrical Engineering Sector from the Aspect of Financial Management

Jana Kajanová[1], and *Natália* Barteková[1,*]

[1]Comenius University Bratislava, Faculty of Management, Odbojárov 65/10, 820 05 Bratislava, Slovakia

Abstract

Research background: The electrical industry can be considered one of the main pillars of the Slovak economy. The Slovak electrical engineering sector is one of the areas that have been quite strongly affected by globalisation over the last 20 years. This is evidenced by the fact that in 2021, 39% of all sales in the sector were produced by only 4 transnational corporations: SAMSUNG Electronics Slovakia s.r.o., Foxconn Slovakia, spol. s.r.o., Panasonic Industrial Devices Slovakia s.r.o., WHIRLPOOL SLOVAKIA spol. s.r.o.

Purpose of the article: Our research aims to highlight the impact of globalization on the Slovak electrical industry, to compare the development of selected financial ratios of selected companies operating in the electrical sector in Slovakia and to determine the effectiveness of financial management in the Covid-19 period from 2019-2021.

Methods: For the 4 largest players in the Slovak market, following indicators have been examined: net profit, net cash flow, return on assets, return on equity and net profit margin. The subsequent correlation analysis between net profit and net cash flow has been carried out.

Findings & Value added: The impact of globalisation on the Slovak electrical industry is pointed out. Selected profitability indicators are analyzed from 2019 to 2021. According to the research the enterprise with the most effective financial management is determined in the selected sector.

Keywords: *globalization; financial management; electrical industry*

1 Introduction

The electrical engineering sector is considered as one of the main pillars of the Slovak economy. The current situation on the market reflects both — traditional electronics

---

manufacturing (power generators, telephones, radios, etc.) and new trends especially connected to the growing automotive industry in Slovakia (electric motors, microelectronics, sensors). The ongoing shift towards e-mobility is creating whole new opportunities for all electrical component suppliers. The electrical engineering sector is one of the strongest contributors to the country's GDP, plays a significant role in the industrial output, and is also one of the biggest employers in the country. This sector employs over 45 000 people (SARIO, 2021).

The Slovak electrical engineering sector is one of the areas that have been strongly affected by globalisation over the last 20 years. Globalization has significantly influenced the electrical engineering industry as a specific representative of the latest science and technology results by a synergistic effect that greatly improves the quality of production of other industrial sectors, especially the mechanical engineering industry. This is evidenced by the fact that in 2021, 39% of all sales in the sector were produced by only 4 transnational corporations which are more than 51% owned by investors from South Korea, Taiwan, Japan, and the USA (Finstat, 2022). Electrical engineering companies are located across whole Slovakia. Some regions have had historically a strong tradition in this sector, while others have been shaped by new global players and their suppliers coming to the region. A significant number of companies are connected to the automotive industry supplier network. The electrical engineering industry is not created by just a few big companies. A large number of medium and small companies have a long tradition. Moving to a circular economy requires manufacturers and producers to rethink their business models for a stronger value proposition and delivery. Many businesses have implemented circular economy business models with different design options to accomplish sustainable business goals and economic prosperity (Pollard et al., 2021; Vishwakarma et al., 2022; Kim et al., 2022; Naik and Eswari, 2022). The most important 4 enterprises in the Slovak electrical engineering sector are SAMSUNG Electronics Slovakia s.r.o. (LCD moduls and LED screens), Foxconn Slovakia, spol. s.r.o. (LCD and OLED TVs and printed circuit boards), Panasonic Industrial Devices Slovakia s.r.o. (control boards, chargers, speakers, sensors) and WHIRLPOOL SLOVAKIA spol. s.r.o. (household appliances). These 4 key representatives generated the bigger volume of operating revenue in the selected sector in 2021 (SARIO, 2021). This study aimed to analyze and describe financial management by using profitability indicators of electrical engineering companies and determine the effectiveness of financial management from the aspect of the pandemic.

Financial management enables us to decide responsibly on business investments and to ensure the necessary financial stability. Financial management focuses on decisions with a tendency to obtain the necessary capital. Profitability is the best measure of a company. Increasing profits show that a company can pay dividends and that the share price will trend upward (Kiseľáková and Šofranková, 2020; Jang and Ahn, 2021). Creditors will loan money at a cheaper rate to a profitable company than to an unprofitable one. The common profitability measures compare net profit with sales, assets, or equity: net profit margin, return on assets and return on equity. Return on assets (ROA) presents the overall effectiveness of the inserted capital using regardless of the source of coverage. The indicator is released about the amount of profit-generated assets (Kuč and Kaličanin, 2021). Return on equity (ROE) presents the profitability of capital inserted by shareholders or business owners. ROE is a key indicator based on which investors decide to pick stocks (Yu et al., 2022). Net profit margin represents the company's ability to achieve profit at a given sales amount (Zhang and Xie, 2022). Assessing the uncertainty of cash flows, along with where they originate and where they go, is one of the most important objectives of financial reporting. It is essential for assessing a company's liquidity, flexibility, and overall financial performance (Kiseľáková et al., 2020). Financial indicators provide relevant information that helps to determine if companies lead to bankruptcy or will have other financial problems in the future.

It is demonstrated by the fact that even experienced companies regardless of their age may commit a failure process in which financial problems or performance decreases are not observable in the last financial report before bankruptcy (Lukason and Laitinen, 2019).

In 2019 there was research that examined the financial health of individual electrical engineering companies in Slovakia by using the Taffler model, Springate model, and the Aspect Global Rating (Stefko et al., 2019). In the Slovak electrical engineering sector, research has not previously been done to compare profitability indicators to determine the enterprise with the most effective financial management. After an extensive review of the literature, it is understood that there has not been a substantial study on the financial management performance of the Slovak electrical engineering sector considering underwriting profitability indicators. The main contribution of this study is a comparison of financial management of 4 key enterprises in the electrical engineering industry in Slovakia.

The research question is which company in the Slovak electrical engineering sector has had the most effective financial management during the COVID-19 pandemic? We want to compare an attitude in financial management in the electrical engineering sector during the COVID-19 pandemic and explore which attitude seems to be the best way. The paper is structured as follows: in the introduction was carried out the literature review and were introduced basic research goals, in section 2 are introduced the data used in the analysis and the methodology. In the next step are presented results, which are discussed in section 4.

2 Methodology

The analysis has been performed by using the data from the statistical database FinStat.sk, which monitors enterprises' income and business activities in the Slovak Republic and is the only source of microeconomic data based on harmonized bookkeeping principles. This database provides accounting information that has been necessary for our research. Finstat analyzes the accounting resources of each company. Finstat cooperates with reliable resources such as the Commercial Register, Trade Register, Register of Financial Statements, Register Bankruptcies, Lists of Insurance Borrowers, and Judicial Decisions (Finstat, 2022).

The first research question is which company in the Slovak electrical engineering sector has had the most effective financial management during the COVID-19 pandemic? We have chosen these 4 key representatives of the selected sector because of the bigger volume of Operating revenue. Operating revenue including the sale of non-current assets and securities of the sample is presented in Table 1.

Table 1. Operating revenue in 2019-2021 [€]

Operating revenue	2021	2020	2019
SAMSUNG Electronics Slovakia s.r.o.	1 696 779 000	1 310 098 000	1 506 890 000
Foxconn Slovakia, spol. s.r.o.	1 138 542 000	1 004 596 000	1 205 095 000
Panasonic Industrial Devices Slovakia s.r.o.	337 254 722	269 425 693	249 101 271
WHIRLPOOL SLOVAKIA spol. s.r.o.	286 669 000	253 272 000	260 467 000

Source: Finstat (2022)

The database Finstat provides already calculated profitability indicators for every electrical engineering company in the period and this paper's results of indicators have been compared. In this study profitability indicators have been used: ROA, ROE, and net profit margin. The calculation for profitability indicators is expressed in Table 2.

Table 2. Profitability indicators formula

Profitability indicators
$ROA = \dfrac{Net\ Profit}{Total\ Asset}$
$ROE = \dfrac{Net\ Profit}{Total\ Equity}$
$Net\ Profit\ Margin = \dfrac{Net\ Profit}{Total\ Revenue}$

Source: Kabát et al. (2013)

Return on Asset (ROA) is the net profit expressed as a percentage of the total asset. A higher ROA number means better utilization of the company's assets. Return on Equity (ROE) is net profit expressed as a percentage of the total equity. ROE expresses how profitably the company is using the owners/shareholders' funds to yield profits. Net profit margin is the percentage of profit a company produces from its total revenue. It measures the amount of net profit a company obtains per euro of revenue gained (Kabát et al., 2013).

3 Results

Financial profitability is the individual ability to make a profit from a particular investment. It is a measure closer to investors and owners and is conceived as the relationship between net profit and net worth of the company. The indicators of profitability in a business or a company are those that serve to determine the effectiveness of the project in the generation of wealth, that is, that allows to control of the balance of expenses and benefits, and thus guarantee the return.

The financial statements of these 4 enterprises have been used as resources for our research. We have analyzed financial statements for calculating profitability indicators. Financial statements and data from their health insurance companies in Slovakia from 2019 to 2021 have been collected to fulfill the aim of the study.

The results for the ROA indicator in the period from 2019 to 2021 are aggregated according to individual electrical engineering companies and are presented in Figure 1.

The ROA indicator expresses the net profit as a percentage of the total asset. A higher ROA number means better utilization of the company's assets. Due to IFRS financial reporting companies, the ROA median value of industry ratio was 1,1% (2019), 2% (2020), and 2,8% (2021) (Ready Ratios, 2022). Based on the results in Figure 1 there was an approximately constant level of ROA indicator from 2019 to 2021 in three companies. Only Panasonic reached a significant increase in the selected period. In terms of the ROA indicator in 2021, Whirlpool performed best at 5,3%. In other words, every 1 euro of assets produced 5,3 cents of net profit. Samsung produced 4,6 cents of net profit for every 1 euro of assets and Foxconn produced 2,5 cents.
Figure 1. ROA growth in the electrical engineering sector 2019-2021

Source: own elaboration (Finstat, 2022)

In comparison, Panasonic produced 0,9 cents of net profit for every 1 euro of assets. We should notice an obvious difference in 2019 Panasonic produced 6,8 cents of net loss for every 1 euro of assets.

The results for the ROE indicator in the period from 2019 to 2021 are aggregated according to individual electrical engineering companies and are presented in Figure 2.
Figure 2. ROE growth in the electrical engineering sector 2019-2021

Source: own elaboration (Finstat, 2022)

The ROE indicator expresses net profit as a percentage of the total equity. Due IFRS financial reporting companies, ROE median value of industry ratio was 0,6% (2019), 1,5% (2020) and 4,7% (2021) (Ready Ratios, 2022). Based on the results in Figure 2 there was a significant depression in the ROE indicator from 2019 to 2021 in Whirlpool but still reached the best position at 25,5%. The other two companies noticed an approximately constant level of ROE in the reporting period. There was an obvious difference from 2019 to 2021 when Panasonic produced at the level of 31,1 cents of net loss for 1 euro of equity and moved to the level of 3,4 cents of net profit.

The results for the net profit margin indicator in the period from 2019 to 2021 are aggregated according to individual electrical engineering companies and are presented in Figure 3.

Figure 3. Net profit margin growth in the electrical engineering sector 2019-2021

Source: own elaboration (Finstat, 2022)

Net profit margin is the percentage of net profit a company produces from its total revenue. It measures the amount of net profit a company obtains per euro of revenue gained. Due to IFRS financial reporting companies, the net profit margin median value of the industry ratio was 1,2% (2019), 2,7% (2020), and 3% (2021) (Ready Ratios, 2022). There was an approximately constant level in the net profit margin indicator from 2019 to 2021 in three companies and a significant increase in Panasonic. In terms of the net profit margin indicator in 2021, Samsung performed best at 3,5% and Whirlpool performed very similarly at 3,4%. In other words, every 1 euro of total revenue produced 3,4 cents of net profit. Foxconn produced 1,2 cents of net profit for every 1 euro of total revenue. In comparison, Panasonic produced 0,5 cents of net profit for every 1 euro of total revenue. There was an obvious difference from 2019 to 2021 when Panasonic produced at the level of -3,5 cents of net loss for 1 euro of total revenue and moved to the level of 0,5 cents of net profit.

The results for the net profit in the period from 2019 to 2021 are aggregated according to individual electrical engineering companies and are presented in Table 3.

Table 3. Net profit in 2019-2021 [€]

Net profit	2021	2020	2019
SAMSUNG Electronics Slovakia s.r.o.	56 927 000	45 874 000	52 298 000
Foxconn Slovakia, spol. s.r.o.	13 710 000	12 115 000	12 362 000
Panasonic Industrial Devices Slovakia s.r.o.	1 742 155	-3 627 558	-8 661 812
WHIRLPOOL SLOVAKIA spol. s.r.o.	9 641 000	9 082 000	9 687 000

Source: own elaboration (Finstat, 2022)

Net profit is the amount of money that a company has after all its expenses are paid. In the pandemic year, 2020 the value of net profit decreased in 3 companies and only Panasonic improved the level of net loss to -3 627 558 €. In terms of the net profit in 2021, all 4 enterprises generated a higher volume of net profit. The highest increase in net profit produced Samsung by 24%. For Panasonic, there was an obvious difference between 2020 when generating net loss and 2021 when already generated net profit with an improvement of 148%.

The results for the net cash flow in the period from 2019 to 2021 are aggregated according to individual electrical engineering companies and are presented in Table 4.

Table 4. Net cash flow in 2019-2021 [€]

Net cash flow	2021	2020	2019
SAMSUNG Electronics Slovakia s.r.o.	-23 450 000	11 993 000	161 251 000
Foxconn Slovakia, spol. s.r.o.	-8 000	9 000	-18 000
Panasonic Industrial Devices Slovakia s.r.o.	361 371	-57 991	-667 773
WHIRLPOOL SLOVAKIA spol. s.r.o.	-2 832 000	1 609 000	1 365 000

Source: own elaboration (Finstat, 2022)

Net cash flow is the amount of cash generated or lost over a specific period. In the pandemic year, 2020 the value of net cash flow surprisingly increased in 3 companies and only Samsung deteriorated by 93%. In terms of the net cash flow in 2021, 3 enterprises generated a lower volume of net cash flow and only Panasonic improved its level of net cash flow at a positive 361 371 €. At the same time, as the only company that generated positive net cash flow in 2021. There are times when a company can have negative cash flow while reporting positive net income.

4 Discussion

The electrical engineering industry produces and sells electronic equipment for industries and electronics products for consumers such as televisions, mobile devices, and printed circuit boards. The industry includes telecommunications, electronic components, appliances, industrial electronics, and consumer electronics. Electronics companies may produce electrical equipment, manufacture electrical components and sell items at retail to make their products available to consumers. Globalisation is a word that many companies use to describe their business. However, globalization includes different approaches to the market. For some, globalization means having several branches scattered around the world. For others, it means having their products and services available in major industrial centers around the world. For very few companies, globalisation means doing business to provide

services around the world as efficiently and easily as in a small village. Globalisation has significantly influenced the electrical engineering industry as we could see that in 2021, 39% of all sales in the sector were produced by only 4 transnational corporations which are more than 51% owned by investors from South Korea, Taiwan, Japan, and the USA. On the list of the TOP 25 electrical engineering enterprises in Slovakia with the highest operating revenue in 2021, all of them are foreign direct investments mostly from Europe and Asia (Finstat, 2022). The global approach of the 4 selected companies is to provide products and services in major industrial centers around the world and also an important role plays e-business.

We analyzed the ROA indicator, in 2021 Whirlpool performed best at 5,3%. Samsung produced 4,6 cents of net profit for every 1 euro of assets. These two companies achieved the best values of ROA in the reporting period. Panasonic produced the biggest increase in ROA indicator from -6,8% in 2019 up to 0,9% in 2021. There was a significant depression in the ROE indicator from 2019 to 2021 in Whirlpool but still reached the best position at 25,5%. There was an obvious difference from 2019 to 2021 when Panasonic produced at the level of 31,1% of net loss and moved to the level of 3,4% of net profit. In terms of the net profit margin indicator in 2021, Samsung performed best at 3,5% and Whirlpool performed very similarly at 3,4%. Panasonic produced 0,5 cents of net profit for every 1 euro of total revenue in 2021 and this company noticed the biggest improvement among selected enterprises. Net profit is the source of compensation to a company's shareholders. If a company can't generate enough profit to compensate owners, the value of shares will plummet. If a company is healthy and growing (with increased profits), higher stock prices should result. In terms of the net profit in 2021, all 4 enterprises generated a higher volume of net profit than in the previous year. In 2020 Samsung produced a decrease in net profit by 12% and in 2021 increased this value by 24%. For Panasonic, there was an obvious difference between 2020 when generating net loss and 2021 when already generated net profit with an improvement of 148%. Whirlpool generated net profit in the whole reporting period without large swings in values. In 2020 Whirlpool produced a decrease in net profit by 6% and in 2021 increased this value by 6%. The value of net cash flow surprisingly increased in 3 companies and only Samsung deteriorated by 93% in the pandemic year 2020. Samsung's net cash flow decreased in 2020 by 93% and then in 2021 by a significant 196%. Samsung's problem with liquidity was caused by an increase in current receivables. Samsung's financial management should negotiate a shorter period of current receivables with its key customers. Whirlpool's net cash flow surprisingly increased in 2020 by 18% and then in 2021 decreased by a significant 176%. Whirlpool's financial management is very stable with only small economic swings. Whirlpool's net cash flow increased in 2020 because of production depression and related production costs decline, which in 2021 rapidly increased. Panasonic had a significant liquidity problem in 2019, firstly in 2020 its net cash flow increased by 91%, and as the only company that generated positive net cash flow in 2021 with a huge increase of 623%. The successful growth of net cash flow was caused mainly by an increase in current payables and liabilities to employees. This attitude of the financial management of Panasonic improves in the short-term and affects the company's financial health, but they should not forget the reputation of the company. In this research, there are times when a company has negative cash flow while reporting positive net income.

This study aimed to analyze and describe financial management by using profitability indicators for key Slovak electrical engineering companies. Based on this study in the period of a pandemic the WHIRLPOOL SLOVAKIA spol. s r. o. and SAMSUNG Electronics Slovakia s.r.o. used its assets well above the ROA industry ratio median. WHIRLPOOL SLOVAKIA spol. s r. o. reached the best value of the ROE indicator in 2021 at 25,5%. The highest net profit margin generated in 2021 was produced by SAMSUNG Electronics Slovakia s.r.o. at 3,5% but WHIRLPOOL SLOVAKIA spol. s r. o. performed very similarly at 3,4%. SAMSUNG Electronics Slovakia s.r.o. showed the ability to create profit in the

reporting period but it had significant problems with liquidity. WHIRLPOOL SLOVAKIA spol. s.r.o. generated net profit in the whole reporting period without large swings and got smaller problems with cash flow management in the reporting period. Therefore, WHIRLPOOL SLOVAKIA spol. s.r.o. takes the best position in terms of financial management effectiveness in the Slovak electrical engineering sector.

Future research directions may also be highlighted in a problem of the financial health in the Slovak industrial sectors. The limitation of this study was an analysis in a short period of 3 years and a lack of access to management decisions.

Acknowledgments

Abstract

Research background: Predicting the future price of oil is crucial for all participants in the commodity markets who trade oil. Moreover, the prediction of oil prices also has an important impact on the overall economy.
Purpose of the article: The aim of the paper is to analyse the time series of the oil price until 2022 and then to find out what impact the change in the oil price has on the evolution of the electricity price.
Methods: We use a technical analysis to predict the future oil price and a correlation analysis to determine the extent to which the oil price impacts the electricity price. The primary source of data to create the analyses is historical data from online databases from January 1, 2011 to October 1, 2021.
Findings & Value added: In view of all the constructive market fundamentals, we forecast the Brent spot price to average USD 67/BBL in 2022. Price risks that may arise will be skewed towards a higher oil price (up to USD 80/BBL). The correlation coefficient indicates a positive dependence between the oil price and the electricity price. This means that if the oil price changes by one unit, the electricity price will also change by one unit. We see the application benefits of the paper for participants in commodity markets, for analyses of economic variables on GDP, and the fundamental importance of oil futures prices for the future evolution of inflation and production.

Keywords: *prediction; oil price; electricity price; technical analysis; correlation analysis*

1 Introduction

Oil is an important raw material and energy resource and plays a key role in the global industrial economy (Horák et al., 2020). It supports the development of the global economy

---

* Corresponding author: kalinova@mail.vstecb.cz

and society (Timilsina, 2015). The price of oil, like of any other commodity, is shaped by the interaction of supply and demand in the market (Vochozka et al., 2020). The demand is shaped by consumption and is significantly influenced by the economic cycle (Baláž, 2006). In the long run, it evolves according to the global economic growth. A decline in the global economic growth reduces the demand for oil. The overall world demand for oil is increasing due to the economic growth in countries such as China, Brazil, India and Russia (Mareček and Machová, 2018). Therefore, what we find on the radar of investors in the oil market is the GDP growth figures mainly from the world's largest economies (Ropa.cz, 2021).

On the supply side, however, in addition to oil stocks, it is also necessary to take into account the impact of OPEC cartel regulation, natural disasters and the threat of military conflicts associated with embargoes on exports to a particular country (Gaspareniene et al., 2022). As oil is traded on commodity exchanges, speculative behaviour by investors can have both stabilising and not stabilising effects on prices. The effects of price changes are different for oil importing and oil exporting countries. For net importers, price increases will cause a deterioration in the balance of trade and negatively affect GDP. Exporters, on the other hand, benefit from oil price increases (Baláž, 2006).

The forecasts of demand, supply and prices are essential for all energy market participants (Sanders et al., 2008, 2009), but the oil price predictions are particularly important because of the impact of oil prices on all aspects of energy markets, on commodity markets and on overall economic activity, GDP growth and inflation (Mamatzakis and Koutsomanoli-Filippaki, 2014).

The aim of this paper is to analyse the time series of the oil price up to 2022 and then to find out what impact the change in oil price has had on the evolution of electricity prices up to 2022. We will use a technical and a correlation analysis to obtain the results.

To meet the objective, the following research questions are formulated:

RQ1: What is the prediction of the futures price of oil until 2022?

RQ2: What is the projected impact of a change in the price of oil on the price of electricity until 2022?

2 Literature research

Alquist et al. (2011) sought a reliable model for forecasting real and nominal oil prices that would benefit all oil importing and exporting countries. As the oil futures market plays an important role in information aggregation and price discovery, the prices of oil futures contracts traded on exchanges such as the New York Mercantile Exchange or the Intercontinental Exchange are commonly perceived to reflect market participants' expectations of future oil prices (Alquist and Arbatli, 2010). Moreover et al. (2013) show that over longer horizons, which are important for policymakers, the predicted performance of the oil futures curve is worse compared to a forecast without considered expectations of market participants. A possible explanation for this finding is that oil futures prices contain a time-varying risk premium. In fact, Hamilton and Wu (2014) find evidence of substantial changes in risk premia in oil futures prices after 2005.

Oil futures, as the most traded commodity futures in the world, play a key role in price fluctuations in the international financial market (Marousek et al., 2015). Therefore, many researchers have analysed the factors influencing the oil futures prices. Using the Markov-Switching Vector Autoregressions (MSVAR) model, Li (2017) concluded that the price of oil futures is directly affected by the positions of investors with the commodity index, and the positions of investors have a significant impact on the returns of oil futures. The price of oil futures as a financial derivative is affected by the behaviour on financial markets. The

investment strategy of commodity index investors is to control the direction of the oil futures market and then influence the fluctuation of oil prices. Guo (2018) concluded that the price of oil futures is affected by various factors such as supply and demand, exchange rates, political relations and international financing.

Zhao (2012) used the cointegration theory and the Granger causality test to conclude that there is a cointegrating relationship between energy and carbon futures prices and a causal relationship between the natural gas price, the electricity price and the carbon futures price. Using two dynamic correlation estimators, i.e., rolling correlation and dynamic conditional correlation multivariate GARCH, Lu et al. (2014) provided empirical evidence of time-varying information spillovers between global oil markets (Beckmann et al., 2014).

The authors point out that the adjustment of spot returns to the forward premium follows a nonlinear path consistent with smooth transition models. There is empirical evidence that investors commonly use futures contracts to hedge uncertain risks, to protect their portfolios and to avoid sudden price changes (Dergiades et al., 2012). Along these lines, Vacha and Barunik (2012) use wavelet coherence to uncover interesting dynamic correlations among energy commodities.

In communicating policy decisions, many central banks have emphasised the importance of oil futures prices for the future inflation development. Until recently, central banks and international organisations tended to rely solely on the oil futures curve to forecast the oil price (Rousek, 2020). However, recent research has shown that models incorporating economic determinants of the oil price, such as changes in oil inventories, oil production, and real global economic activity, can provide more accurate forecasts than oil futures prices (Alquist, Kilian, and Vigfusson, 2013; Baumeister and Kilian, 2014; Baumeister, Kilian, and Zhou, 2013).

This finding is also true in a real-time forecasting environment where oil price predictors are only available with a delay and are subsequently revised repeatedly (Baumeister and Kilian, 2012).

3 Data and methods

The data on the price of Brent oil were obtained from one of the largest Czech portals Kurzy.cz and from the financial portal Finex.cz, and covered the period from 1 January 2011 to 1 October 2021. The values were measured in USD per barrel/BBL (159 litres) in monthly terms over the last ten years. Graph 1 shows a line graph of the time series of the Brent oil price from 2011 to 2021. Since 2009, the oil price volatility has had a tendency to get higher. In this context, the long-term trend of oil prices is important to ensure future economic stability in many countries, as oil price changes and unstable oil supply can seriously affect their economies that depend on oil imports and exports (Singer, 2007; Olomola and Adejumo, 2006). The biggest drop in the price of oil was recorded in February 2020 due to the global pandemic, when Chinese authorities reported 19,461 newly confirmed cases of covid-19. From March 2020 onwards, the number of countries with infection began to increase exponentially, and these countries started to implement anti-pandemic measures, which had an impact on the economies of the countries. The prices shown in Graph 1 are the spot prices of Brent crude oil, which is one of the types of oil traded on the Exchange right next to WTI crude oil.
Graph 1. Brent crude oil price time series 2011 – 2021.

Source: Author

Most oil price forecasts are produced by commercial institutions (oil companies, banks, investment groups or large traders) and are intended only for the needs of those institutions or of a small circle of subscribers. For example, Moghaddam et al. (2018) compare the estimates of 13 institutions by evaluating the evolution of their oil price forecasts on three fixed dates. They use the criteria of the forecast efficiency and the forecast fairness to do so, and also examine possible sources of failure to meet these criteria.

In this paper, the methodology is based on estimating the future value for a short period of one year. To predict the oil price in the future year 2022, linear function Linertrend in Microsoft Excel was selected, which predicts the future development based on the historical data. The function finds the predicted value from the area of two cells whose relationship can be captured by a linear dependence. For the period from 1 October 2021 to 1 December 2022, 14 samples will be predicted (14 months). The variable y is a set of values derived from the relation y = mx + b and corresponds to the values obtained from the past period and the spot price of oil. The variable x is a set of values to which the values of the y field correspond. In this case, it is the individual period x. The new x between 1 October 2021 and 1 December 2022 is a set of values for which the function calculates the corresponding values for 2022. The logical value of b is a parameter and determines how we calculate the linear dependence. To find the prediction of the future electricity price, we applied an identical procedure as for the prediction of the oil price. Using a linear trend, the new x is predicted.

In order to predict future oil prices, it is necessary to consider factors that significantly affect the price of oil and cannot be predicted by the market, such as weather and natural disasters, or military conflicts and geopolitical reasons. The most important factor influencing the oil price increases is the supply/demand ratio. Factors can be long-term (economic expansion) or short-term (seasonal changes).

In order to determine the oil price and electricity price dependence, we created a correlation analysis from historically available data from 1 January 2011 to 1 October 2021. The correlation analysis is shown in the correlation (dot) diagram created in Microsoft Excel in Graph 4. To determine the existing relationship between the oil price and the electricity price, the correlation was calculated using the correlation coefficient through the Correl function, where the oil price was the cell area of matrix 1 and the electricity price was the cell area of matrix 2.

4 Results

Technical analysis was performed using previously collected historical data, extended by a linear trend followed by a forecast of the Brent crude oil spot price for 2022. Graph 2 shows the two rising lines of the linear trend, or the forecast for 2022, from a short period of two years from October 1, 2019 to October 1, 2021 and three years from October 1, 2018 to October 1, 2021. This technical analysis forms two outputs that are part of our future forecast. The final prediction is extended by various expert analyses. The forecast is primarily based on the upward trends from the outputs shown in Graph 2, which are mutually compared.
Graph 2. Oil price time series with subsequent prediction for 2022.

Source: Author

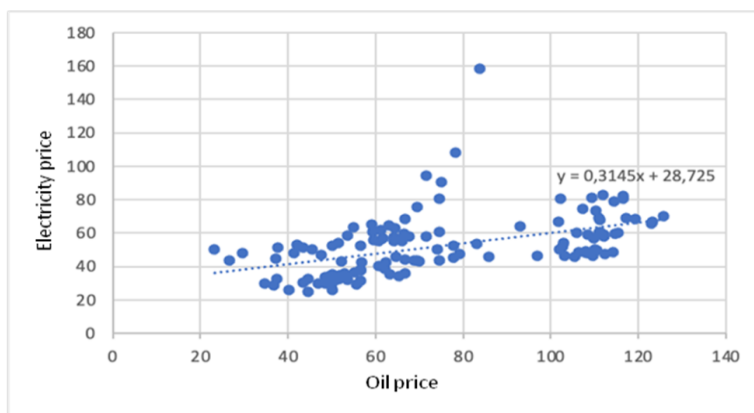
Graph 2 shows a line graph of the oil price time series, extended by a linear trend with a prediction of future developments until 2022. In June 2008, the world oil prices, which had had an upward trend since 2003, rose to $134/BBL. The oil prices declined after the global economic crisis in 2008 but started to rise again in early 2009 (Farzanegan and Markwardt, 2009). Buetzer et al. (2012) suggested possible explanations for such a projected slowdown in oil demand growth, such as structural changes in the global economy, consumer reaction and government policies. Since the crisis, the world economy has been recovering and growing continuously due to high demand. The years following the crisis were favourable for the OPEC cartel due to higher prices which brought them higher profits. It can be seen that from 2014 onwards the price of oil started to fall after OPEC decided to maintain oil production in 2014. The price of oil fell below $50/BBL and the biggest drop was in 2020. The sharp drop in the price of oil in 2020 was caused by the global pandemic of covid-19, with the price falling to almost $23/BBL in March.

Uncertainty grew steadily because of the newly rising confirmed covid cases, causing panic in the financial markets. The price at the end of 2020 rose above $50/BBL for the first time since March 2020 due to expectations that many countries would introduce vaccination against covid-19, which would accelerate the recovery in energy demand. Currently, aviation remains the weakest part of global oil demand. The price of oil per BBL surpassed $80 in

October 2021, the first time in more than three years, due to the recovery of the global economy and demand. Its value climbed to USD 81.5/BBL (O energetice.cz, 2021).

The diagram in Graph 3 shows a line graph of the electricity price followed by a prediction for 2022. To answer the second research question, the below graph was created using historical data identical to the spot oil price followed by a prediction from two time periods.
Graph 3. Electricity price time series with subsequent prediction for 2022.

Source: Author

Graph 4 shows a correlation diagram that illustrates the statistical dependence of the observed variables oil price and electricity price for the last ten years from 1 January 2011 to 1 October 2021. We have interleaved this Graph with a linear line whose equation is y = 0.3145x + 28.725.


Graph 4. Correlation analysis - oil price and electricity price dependence 2011 – 2021.

Source: Author

To find out the existing relationship between these variables, we calculated its correlation using the correlation coefficient. The correlation coefficient of the oil price and the electricity price takes a positive value of 0.4721549, which indicates an average existing dependence of the relationship between the oil price and the electricity price. In this case, it means that if

the price of oil changes by one unit, the price of electricity changes by one unit at the same time.

5 Discussion

Based on the results obtained, we are able to answer the research questions that have been set.

RQ1: What is the prediction of the oil futures price until 2022

The historical data from 1 October 2018 on Graph 2 was used as the basis for creating a technical analysis that predicted future Brent crude oil prices until 2022. The linear trend method was used for two periods, 1 October 2018 – 1 October 2021, and 1 October 2019 – 1 October 2021. From this analysis, two outputs are obtained (see Graph 2) using two increasing linear trend lines. The outputs were then compared and extended them with further expert analyses. Based on these outputs, it was possible to make a prediction.

The oil futures price curve will rise slowly until 2022. Graph 2 shows a gradual rise in the Brent crude oil spot price in the future year 2022. However, the linear trend does not include certain factors affecting the oil price that should be taken into account. The relevant factor that cannot be avoided is primarily the political situation. Currently, the global pandemic of covid-19 has unfavourably affected the demand for oil, which has caused an unexpected shortfall in exporters' revenues. Due to the increasing number of infected people, countries have been implementing strict restrictive measures. However, the price of oil can also be affected by international demand for petroleum products (AIP, 2013).

In selecting the factors influencing international oil price fluctuations, some time series include daily data, such as the US dollar exchange rate. Cartels, such as the Organization of the Petroleum Exporting Countries (OPEC), can also influence the price of oil (finex.cz, 2021). However, their aim is to keep prices stable or only slightly fluctuating. Given the competition from WTI oil, it would be necessary to adjust the prices again.

The estimates for the year 2022 according to Platts Analytics predict an increase in the global demand for oil by 4,7 million barrels a day, thus reaching 103,2 million barrels a day, which is on annual average by 700 000 a day more than before the pandemic (Spgobal.com, 2021). In contrast, EIA (Environmental Impact Assessment) predicts that the price of Brent oil decreases from the average value of 84 USD/bbl in October 2021 to 66 USD/bbl in December 2022 and the price of WTI will decrease from the average value of 81 USD/bbl in October 2021 to 62 USD/bbl in December 2022. Expert estimates by EIA predicted that the global consumption of oil would exceed the production of oil for five consecutive quarters, starting from the third quarter of the year 2020. During this period, oil reserves in OECD (Organisation for Economic Co-operation and Development) decreased by 424 million barrels, which accounts for 13 %. The forecast is that the global demand for oil will exceed the global supply by the end of the year, thus contributing to further decreasing of oil reserves and keeping the price of Brent oil above 80 USD/bbl until December 2021. However, the global oil reserves will start to be created in 2022, thanks to rising production from OPEC+ countries and the USA due to the slowing growth of global oil demand. This shift is expected to decrease Brent oil, which is predicted to be 72 USD/bbl in 2022 (Independent Statistics Analysis, 2021).

In response to all constructive market fundaments, it could be assumed that the spot price of Brent oil in 2022 will be 67 USD/bbl on average. The price risks that may arise will be skewed towards a higher price of oil. In the case of tightening the market balance, the possibility of an increase in oil price up to 80 USD/bbl cannot be excluded. Based on the

comparison of outputs from technical analysis, the prediction from the period 1 October 2018 – 1 October 2021 will be prioritized.

RQ2: What is the projected impact of a change in the price of oil on the price of electricity until 2022?

The price of electricity in general shows a slight correlation of 0.4721549 with the development of oil prices. Since oil as fuel plays only a small role in the production of electricity, the prices of oil and oil products have only a small direct effect on electricity prices in Europe (Impact of the Oil Price on EU Energy Prices, 2014). The calculated correlation coefficient reaches a positive value of 0.4721549, which confirms the existence of the relationship between the monitored variables, oil price and electricity price for the last ten years. Various views of the impact of oil prices on the global economy have been formulated. Several studies found that higher oil prices have an adverse effect on economy (Akpan, 2009; Amano and Van Norden, 1998). Based on the obtained results, it can be predicted that if oil price decreases from 74,32 USD to 67 USD, electricity price will grow or decrease by a unit. The development of the price of these commodities is influenced also by environmental emission production from renewable resources.

6 Conclusion

The goal of the paper was to predict future spot prices of Brent oil and its effect on electricity prices until 2022. On the basis of performed technical analysis, future values of spot prices of Brent oil traded on the Stock Exchange were predicted. The obtained historical values were used as a basis for creating a linear trend from two different periods. The technical analysis had two outputs and the prediction was based primarily on the increasing trends of these two outputs. Correlation analysis was applied to determine the impact of oil prices on electricity prices. To confirm the existing relationship between these variables, correlation coefficient was calculated, which reached positive values, which could be seen as a confirmation of the existing relationship between oil price and electricity. It can thus be assumed that if the price of oil changes by one unit, the price of electricity will also change by a unit.

At present, it is not easy to predict the future oil prices. This prediction was thus made for a short period of fourteen months. The essential factor was that expert analyses were incorporated into the outputs of technical analysis. The accuracy of the prediction was also determined by fundamental factors that could be predicted to some extent; however, there are many non-market factors that cannot be predicted, such as political situation, changes in the strategy of the OPEC cartel, as well as the spread and the development of new mutations of COVID-19. In making resulting prediction, which included fundamental factors extended by other expert analyses, the prediction until the year 2022 from the period of three years, from 1 October 2018 to 1 October 2021.

The application benefits of the paper can be seen for the participants in commodity markets trading in oil and electricity, for the analysis of the impact of the economic variables on GDP, and the fundamental importance of oil futures prices on the future development of inflation and production. The output of the prediction of the curve of futures oil and electricity prices was information corresponding to the actual situation on these commodity markets.

Corporate Debt Financing in the Building Project Development Sector (Characteristics of National Companies and Companies under Foreign Control)

Dagmar Kalová[1,*]

[1] Brno University of Technology, Faculty of Business and Management, Kolejní 2906/4, 612 00 Brno, Czech Republic

Abstract

Research background: Major corporate entities operating in the property development sector are companies that are part of corporate groups which create a network of affiliated entities associated with certain advantages and disadvantages. One of the benefits is being able to better utilise one's resources and achieve better performance. It can be stated that these companies show significant specific characteristics in the area of debt financing.

Purpose of the article: The aim of the paper is to assess the existing practice of utilizing debt financing in the sector. The object of interest was national companies, companies under foreign control, non-affiliated companies and affiliated companies. Those indicators that were assessed are: cost of debt, interest coverage and corporate indebtedness. Company payables to banks and controlling or controlled entities were observed.

Methods: Data were obtained from several sources. This was a combination of data from databases and from publicly accessible national registers. Companies were divided into categories according to ESA 2010 classification and according to the corporate group size level. The relevant quantitative data was acquired from financial statements such as data on interest expense and similar expenses, payables etc.

Findings & Value added: The results of the research indicate that companies which are part of corporate groups have significant representation in the sector. It was shown that companies under foreign control are part of bigger corporate groups as opposed to national companies. When assessing the cost of debt indicator no greater differences were found between national companies and companies under foreign control.

Keywords: *debt financing, cost of debt, interest coverage*

1 Introduction

A company that becomes part of a corporate group brings significant competitive advantages. Affiliated companies as opposed to non-affiliated companies can pool the group's common resources (Aguilera et al., 2020; Lin & Yeh, 2020; Min et al., 2022), for example, use loans from affiliated entities or draw bank loans guaranteed by affiliated entities (Lin & Yeh, 2020). Pooling capital resources becomes more important with the limited options of obtaining external financing or with the high costs of debt financing (Cooper & Nguyen, 2020). Affiliated companies have easier access to external financing (Cainelli et al., 2019) and can obtain bank loans more easily (Cainelli et al., 2019). Pooling resources contributes to the financial independence of affiliated companies (Lin & Yeh, 2020) and improves their investment conditions, (Lin & Yeh, 2020). Møen et al. (2019) divides debts into external (to a third party) and internal (to any affiliated entity). Goldbach et. al. (2021) followed up the findings of Møen et al. (2019), while dividing debts into external (to a third party), parent (to a parent company) and internal (to other affiliated entities outside the parent company).

Among the benefits of companies becoming part of a group and pooling common resources are: i) independence of external financing: Pooling capital resources is a substitute for external financing (Cainelli et al., 2019). ii) easier entry into the sector: Pooling capital resources creates better conditions for entry into the sector (Aguilera et al., 2020). International corporate groups can pool their resources with local companies and make use of competitive advantages in the form of pooling cross-border capital resources (Fisch & Schmeisser, 2020). The disadvantages of companies becoming part of a group are: i) more complex management: Unlike non-affiliated companies, corporate groups have a more complex management structure (Li et al., 2022) and the difficulty of management increases with the size of the group (Min et al., 2022). ii) competition between companies: Although companies within a group cooperate, they also compete with each other (Li et al., 2022).

A group's resources can be redirected to a company as financial resources for strengthening its equity or as foreign capital (debts). Debt financing is more interesting for companies from a tax perspective (Cooper & Nguyen, 2020), the interest tax shield reduces the costs of debt. National companies can only make use of a standard interest tax shield whereas companies under foreign control can also use the international interest tax shield (Goldbach, 2021). Using debt financing while pooling resources is a means for tax optimisation (Cooper & Nguyen, 2020, Møen, 2019, Goldbach, 2021). However, this method of financing also brings tax risks as for example companies can face suspicion of abusing these transactions for profit shifting (Cooper & Nguyen 2020). OECD (2020) also assumes possible abuse. The aim of OECD (2020) is to set the rules for appraising fees for the use of debt financing among affiliated entities in the same way as if fees were to be set by non-affiliated entities.

Goldbach et al. (2021) urge further research in this area in order to understand the operational reasons for using debt financing between affiliated entities. The authors point out that tax savings are not the only goal of pooling a group's resources (Goldbach et al., 2021). Examining specific industries is also important since this way it is possible to gain more specific knowledge (Li et al., 2022).

The building project development sector in the construction industry was analysed through the conducted survey. The construction industry is a sector in which financial leverage is used and is strongly dependent on the availability of credit (Oh & Yoon, 2020). The principal production factor of companies operating in the sector is capital and the group's pooling of capital resources can be an important competitive advantage.

2 Aim and Methods

The conducted survey builds on the idea of the research of Joni et al. (2020), who examined the differences in capital expenses in one country (Indonesia) among the selected corporate groups in various sectors. The subject of this survey is also the situation in one country, which is the Czech Republic. The research focused specifically on the Building Project Development sector. It does not observe total capital expenses instead the research focuses specifically on debt financing expenses. The benefit is that the situation is assessed in one country and one specific sector. The selected sector is characterised by the small number of companies that operate in it, is challenging in terms of capital and socially significant.

The aim is to assess the use of debt financing and the cost of debt in selected categories of companies and expand the existing awareness of the use of debt financing by knowledge specific for one particular sector and one particular country. The observed quantity is the Cost of Debt in the period (hereinafter "t") of 2018. To achieve the goals the following variables were determined and assessed: i) affiliation to a corporate group (yes or no), ii) company size (measured size of assets and size of net turnover), iii) indebtedness. The survey was conducted for different company categories (non-affiliated companies, affiliated companies, national companies, companies under foreign control). As Aguilera et al. (2020) state, the definitions of a corporate group are entirely clear nevertheless the problem is to determine companies that are affiliated to a group (hereinafter "affiliated companies"). Information can be obtained from independent sources or from databases (Aguilera et al., 2020). In this survey data were obtained from databases and from several sources. A database was used to identify companies operating in the sector, determine the size of corporate groups and values of interest coverage and total assets (Bureau van Dijk, 2022). The National Administrative Register of Economic Entities was used to divide companies into categories (Ministry of Finance of the Czech Republic, 2022). The financial data of companies was drawn from the national register (Ministry of Justice of the Czech Republic, 2022) and from a database (Bureau van Dijk, 2022).

The basic set was established as of 8 September 2022 according to the following criteria: i) status: active companies; ii) NACE Rev. 2 (Primary Codes and Secondary Codes): 411 – Building Project Development; iii) World region/Country/Region in country: Czech Republic.

The basic set included 530 companies, of these 2 duplicate items. The total number of observed companies was 528 (Bureau van Dijk, 2022). A company was included in the non-affiliated company category if the number of companies in a corporate group was 0. In other cases a company was considered an affiliated company and the size of the corporate group was determined according to the number of companies. Information about the size of the corporate group was obtained from a database (Bureau van Dijk, 2022). The exchange rate of CZK 25.725/EUR was used to convert currency.

In the survey financial statement items were observed from a database (Ministry of Justice of the Czech Republic, 2022), specifically:

    i.   Profit/Loss statement: Interest expense and similar expenses (in subsidiaries/other), Profit/Loss Before Tax. Net Turnover for the period.

    ii.   Balance sheet: Payables, Payables to Banks (long-term liabilities), Payables to controlling or controlled entity (long-term liabilities), Payables to Banks (short-term liabilities), Payables to controlling or controlled entity (short-term liabilities).

The interest coverage and indebtedness indicators were assessed to gain information on the ability to pay interest from borrowed resources. The formulas for the calculations performed are given below.

$$Cost\ of\ debt\ =\ \frac{Interest\ expense\ and\ similar\ expenses}{\frac{(Payables\ (t)+Payables\ (t-1))}{2}} \qquad (1)$$

$$Interest\ cover\ =\ \frac{Operating\ profit}{Interest\ paid} \qquad (2)$$

$$Indebtedness = \frac{Payables}{Total\ assets} \qquad (3)$$

3 Results

Of the total number of 528 companies registered in the Bureau van Dijk database, 22 companies were no longer found in the national register (Ministry of Finance of the Czech Republic, 2022). It was possible to break down 506 companies out of 528 into the categories according to the ESA 2010 classification. In the Building Project Development sector in the Czech Republic private or national non-financial companies (389 out of 586) have the biggest representation, then self-employed person (56 out of 506) followed by private non-financial companies under foreign control (39 out of 506). In the private or national non-financial company category (hereinafter "national companies") affiliated companies (203 out of 389) prevail over non-affiliated companies (186 out of 389). In the private non-financial companies under foreign control category (hereinafter "companies under foreign control") affiliated companies (31 out of 39) also prevail over non-affiliated companies (8 out of 39). Small corporate groups with a maximum number of 10 companies have the biggest representation. Companies under foreign control are especially part of bigger corporate groups. Table 1. describes the incidence of corporate groups in the sector and their size. National companies that are part of corporate groups with up to 10 companies in size (190 out of 234) prevail in the observed categories. For companies under foreign control, corporate groups with more than 11 companies (17 out of 31) prevail over corporate groups with up to 10 companies (14 out of 31).

Table 1. Size of corporate groups in the sector (year 2018)

Companies	Corporate group size (number of companies)					
	1 – 10	11 - 100	101 - 200	201 - 500	501 - 800	Total
National	190	11	1	1	0	203
Under foreign control	14	6	3	4	4	31
Total	204	17	4	5	4	234

Source: own processing (Bureau van Dijk, 2022)

Data on total assets comes from a database (Bureau van Dijk, 2022) and can be seen in 265 companies ((national (237) and under foreign control (28)). In this group, 111 companies were non-affiliated and 154 part of the corporate group. Companies in the sector had total assets in a range of <0; 480,155> EUR 000. The median value of total assets of companies in the sector was EUR 271,000. Companies which are part of a corporate group work with higher total assets and therefore also higher total capital. The median value of total assets in companies under foreign control is several times higher than in national companies. The values measured in individual corporate groups are the following:

- National companies: range <0; 480,155> EUR 000; median EUR 249,000.

- Companies under foreign control: range <0; 156,393> EUR 000; median EUR 1,308,000.
- Non-affiliated companies: range <0; 31,050> EUR 000; median EUR 228,000.
- Affiliated companies: range <0; 480,155> EUR 000, median EUR 289,000.

3.1 Interest coverage of companies that are part of corporate groups

The interest coverage indicator can be found in the database in 94 companies (Bureau van Dijk, 2022). In this group there were 33 non-affiliated companies and 62 affiliated companies, 82 national companies and 12 companies under foreign control. As shown in Figure 1., the interest coverage value ranged in an interval from 1.01 to 10.00 (30 out of 94). Forty companies out of 94 showed a value of interest coverage of less than 1.00, which can infer that a big part of companies was unable to pay interest from operating profit in 2018. No more significant differences in the values of interest coverage were found among national companies and companies under foreign control.
Figure 1. Interest coverage indicator in companies in the sector (year 2018)

Source: own processing (Bureau van Dijk, 2022)

Non-affiliated companies (15 out of 40) and affiliated companies which are part of corporate groups with up to 10 companies (20 out of 40) showed an interest coverage value of less than 1, see more in Table 2.

Table 2. Interest coverage indicator in non-affiliated and affiliated companies (year 2018)

Interest coverage	Non-affiliated companies	Corporate group size (number of companies)				
		1 – 10	11 - 100	101 - 200	201 - 500	501 - 800
less than 1.01	15	20	3	1	0	1
from 1.01 to 10.00	11	13	3	3	0	0
more than 10.00	7	10	4	0	1	2
Total	33	43	10	4	1	3

Source: own processing (Bureau van Dijk, 2022)

Table 3. shows the values of interest coverage for the category of national companies and companies under foreign control. In national companies the values of interest coverage of less than 1.01 (36 out of 82 companies) prevailed and in companies under foreign control most values occurred in an interval from 1.01 to 10.00 (5 out of 12).

Table 3. Interest coverage indicator in national companies and companies under foreign control (year 2018)

Interest coverage	Companies		Total
	National	Under foreign control	
less than 1.01	36	4	40
from 1.01 to 10.00	25	5	30
more than 10.00	21	3	24
Total	82	12	94

Source: own processing (Bureau van Dijk, 2022)

The values of Profit/Loss Before Tax, Cost of Debt and Net Turnover for the period could be found in 92 out of 94 companies (of these 80 national and 12 under foreign control, 32 non-affiliated and 60 affiliated companies). Companies in the sector showed Profit/Loss Before Tax values for the year in a range of <-915; 96,020> EUR 000. The median of all values was EUR 7,000. The median was significantly higher in affiliated companies as opposed to non-affiliated companies. The highest median was found in companies under foreign control. It was 75.8 times higher compared with national companies. The following Profit/Loss Before Tax values are characteristic for individual groups of companies:
- National companies: range < -915; 96,020> EUR 000; median EUR 5,000.
- Companies under foreign control: range < -448; 12,126> EUR 000; median EUR 379,000.
- Non-affiliated companies: range < -915; 943> EUR 000; median EUR 4,000.
- Affiliated companies: range < -448; 96,020> EUR 000; median EUR 9,000.

3.2 Cost of Debt

Cost of Debt includes interest expense and similar expenses made up of two components, which is: i) in subsidiaries and ii) other. The Cost of Debt for the sector in 2018 was in an interval of <0.0; 11.6> %. The median of values was 1.40%. Most companies in this period had a Cost of Debt of a range up to 3% (71 out of 92). No more significant differences were found among national companies and companies under foreign control, see more in Table 4. A maximum of 3% of Cost of Debt values was found in 88% of non-affiliated companies, 72% in affiliated companies, 75% in national companies and 92% in companies under foreign control. The Cost of Debt values in individual groups of companies are as follows:
- National companies: range <0.00;11.60> %; median 1.61%.
- Companies under foreign control: range <0.15;3.31> %; median 1.00%.
- Non-affiliated companies: range <0.10;7.59> %; median 0.99%.
- Affiliated companies: range <0.00;11.60> %; median 1.78%.

Table 4. Cost of Debt in % (year 2018)

Companies	Cost of Debt				Total
	<0.00;3.00>	<3.01;6.00>	<6.01;9.00>	<9.01;12.00>	
National	60	15	4	1	80

Under foreign control	11	1	0	0	12
Total	71	16	4	1	92

Source: own processing (Ministry of Justice of the Czech Republic, 2022)

A significant number of companies (58 out of 92) showed a Net Turnover for the period of up to EUR 1,000,000. The median of values for individual groups of companies are as follows: i) all the companies in the sector: EUR 281,000; ii) national companies: EUR 310,000, iii) companies under foreign control: EUR 57,000; iv) non-affiliated companies: EUR 46,000 and v) affiliated companies: EUR 411,000. Companies prevail with a Net Turnover value for the period of up to EUR 10,000,000 (79 out of 92). Companies in all categories in the Net Turnover range have Cost of Debts mostly up to 3%, see more in Table 5.

Table 5. Cost of Debt in % according to Net Turnover in EUR 000 (year 2018)

Net turnover	Cost of debt				Total
	<0.00;3.00>	<3.01;6.00>	<6.01;9.00>	<9.01;12.00>	
<0;10)	14	0	1	1	16
<10;100)	20	6	0	0	26
<100;1,000)	13	3	0	0	16
<1,000;10,000)	14	4	3	0	21
<10,000;100,000)	9	3	0	0	12
<100,000;1,000,000)	1	0	0	0	1
Total	71	16	4	1	92

Source: own processing (Ministry of Justice of the Czech Republic, 2022)

Most companies have indebtedness of up to 60% (52 out of 92), see more in Table 6. Twenty-nine companies have indebtedness that is higher than 80%, whereas 12 out of 29 reported negative equity (10 national companies and 2 companies under foreign control).

Table 6. Indebtedness of companies in the sector in % (year 2018)

Companies	Indebtedness					Total
	<0;20)	<20;40)	<40;60)	<60;80)	<80;∞);	
National	11	18	17	11	23	80
Under foreign control	2	3	1	1	5	12
Total	13	21	18	12	28	92

Source: own processing (Ministry of Justice of the Czech Republic, 2022)

3.3 Payables (to banks and controlling or controlled entity)

The next part of the survey focused on companies whose financial statements report the Interest Expense and Similar Expenses items, including their components (i) in subsidiaries and ii) other. These items were listed in 80 out of 92 companies (69 national companies and 11 companies under foreign control). A non-zero Interest Expense item and Similar Expenses

item in subsidiaries was reported by 38 out of 80 companies and non-zero Other Interest Expense item and Similar Expenses item was reported by 53 out of 80 companies. Both interest components were reported by 11 out of 80 companies. Most companies (27 out 38) that reported Interest Expense and Similar Expenses in subsidiaries in the financial statements did not report any Similar Expenses to non-affiliated entities. These were specifically 22 national companies and 5 companies under foreign control.

The next to be assessed were reports of Payables to Banks and to a controlling or controlled entity. Non-zero values, at least in one of the items, were reported by 47 companies (38 national companies and 9 companies under foreign control). Payables to Banks were reported by 33 companies, of these long-term and short-term by 12 companies). Payables to a Controlling or Controlled Entity were reported by 10 companies, of these long-term and short-term by 2 companies). Companies mostly reported long-term Payables to Banks, see more in Table 7.

Table 7. Payables to banks and controlling or controlled entity (year 2018)

Companies	Liabilities			
	Payables (Long-term)		Payables (Short-term)	
	to banks	to control (ling/led) entity	to banks	To control (ling/led) entity
National	24	7	14	5
Under foreign control	3	3	4	6
Total	27	10	18	11

Source: own processing (Ministry of Justice of the Czech Republic, 2022)

The median of values for companies which used intra-group financing were i) Net Turnover: EUR 757.5 000 EUR, ii) Profit/Loss Before Tax: 58.5 000 EUR; iii) Total Assets: EUR 3,772,000; iv) Indebtedness: 54%. The median values of Net Turnover, Profit/Loss Before Tax, Total Assets is significantly higher than the median of values of all companies in the sector. So it can be stated that the use of intra-group financing (pooling the group's common resources) presents an important competitive advantage. In specific terms, the pooling of common resources allows affiliated companies to work with higher capital, achieve higher earnings and higher profit.

4 Discussion and conclusions

The aim of the paper was to conduct an analysis of the sector and provide information on the use of debt financing. Research was focused on the assessment of companies operating in the Building Project Development sector in the Czech Republic. Specifically debt financing costs and the interest coverage indicator were assessed. Companies in the sector were divided into the following categories: national companies, companies under foreign control, non-affiliated companies and affiliated companies.

Most companies in the sector came under the category of private or national non-financial companies, which are part of a corporate group. Corporate groups of up to 10 companies mostly operated in the sector. In bigger corporate groups there was a bigger representation of companies under foreign control than of national companies. It can be assumed that companies which are part of a corporate group have significant representation in the sector. In terms of size, these are smaller corporate groupings.

Affiliated companies worked with greater total capital than non-affiliated companies. Companies under foreign control showed much higher total assets than national companies. The median of the Profit Before Tax item was many times higher in companies under foreign control than in national companies. It was also higher in affiliated companies as opposed to non-affiliated companies. The results show that pooling resources within a group and involving foreign capital contributes to higher performance.

The Cost of Debt values in most companies reached a value of up to 3%. Affiliated companies showed a higher median of Cost of Debt values as opposed to non-affiliated companies. No more significant differences were found between national companies and companies under foreign control. The size of companies was not significantly projected in the values of this indicator. To understand the reasons for the measured higher values in affiliated companies, it would be appropriate to focus the next research on determining the Cost of Debt to affiliated and non-affiliated entities.

A large number of companies had up to 60% indebtedness. Interest coverage in many companies was less than 1.00. These companies did not create sufficient operating profit to settle their interest. Interest coverage values have an impact on determining ratings and assessing the credit risk. In this respect, it can be assumed that pooling resources within a group when companies do not create sufficient operating profit, can mean that pooling resources is not just a competitive advantage but also an operational need. Given the long-term duration of development projects it would be appropriate to conduct research covering more periods. The period selected for the survey was not affected by the current problems such as the Covid-19 pandemic and the war in Ukraine. Many companies in the sector had a Net Turnover for the period of up to EUR 1,000,000. It can be assumed that there was a prevalence of smaller companies in the survey.

The conducted survey provides an overview of debt financing in individual categories of companies which were affected by the current problems. It will be possible to build on these findings in further research and determine the impact of the problems on debt financing of the Building Project Development sector.

Abstract

Research background: Social engineering in the context of organizational cyber security is a very widespread adverse phenomenon in the globalized world. Attackers are improving their abilities to lie, extort and cover up their activities. Their goal is to use psychological coercion and other technical skills to confuse the victim and force him to hand over personal data such as ATM card numbers, login data to information systems or other sensitive information. Then they exploit this information for their own enrichment by selling the information to a third party on the black market, or blackmail the victim with a software application called ransomware, which blocks access to the data and asks for money to be sent to a bank account. Healthcare facilities are a frequent target of phishing attacks around the world. The information contained in their information systems is sensitive data, the leakage of which has great negative consequences from the point of view of the law and the good name of the organization.

Purpose of the article: The main idea of this article is present a simple method of phishing attack within a medical facility and will point out the importance of a cyber security awareness development plan.

Methods: Before applying the method of phishing attack, it was necessary to collect relevant information about the organization's cyber security issues that can be affected by social engineering. Subsequently, a potential procedure was created by which the attacker could carry out the attack with minimal financial costs.

Findings & Value added: The main use is to spread knowledge about social engineering. The work describes social engineering in the context of cyber security organizations, as an agent that is used more and more every year for intrusions into the information systems of organizations. Based on the frequency and effectiveness of this type of social engineering, a test was created which it consisted in faking an attack and finding out how many employees of the organization will come across this attack.

1 Introduction

Cybersecurity has come into people's awareness with the development of computer systems and the mass interest in these technical conveniences. Nowadays, almost every household has a computer, and not just one (Salloum et al., 2019), (Ristvej et al., 2017), (Lovecek, et al., 2017). Mobile phones now serve more as computers and not just a means of communicating, over long distances. All these devices are connected to the worldwide internet network.

The Internet is the fastest growing and expanding digital medium in a globalised society (Ristvej et al., 2017). With access to the Internet and the interconnection of all devices in cyberspace, there is a need to protect them (Kampova, 2019). When inspecting devices, detecting malfunctions and shortcomings, it is possible to come across the perpetration of illegal activities. Already in the manufacturing phase of products, software reliability checks must be carried out, most often with the use of hackers, which are persons engaged to penetrate the device's system, to detect its weaknesses and then remove them. Sometimes, updating the device's software or updating an antivirus program is sufficient to prevent penetration into the device's cyberspace (Fatima et al., 2019) These aspects are just a small start of a cybersecurity strategy for (Salloum et al., 2019), (Rehak,2019), (Frank et al., 2022).

The importance of cybersecurity lies in maintaining people's trust in the information and communication technologies that contain their sensitive information (Halaj et al., 2018), (Stojnic et al., 2021), (Rehak and Novotny, 2016). It encourages discussions about why an event happened, who caused it and how, with the aim of eliminating new threats. This issue is one of the most discussed topics by security professionals in 2022, and it has already come to the attention of ordinary people because of the large increase in incidents happening on the Internet, or on people's personal computers, or in the systems of multinational corporations and governments. To this day, various conferences are being held to develop measures against this anti-social activity. Each layer of society looks at cyber security differently, with its own perspective, its own interests.

Phishing is a social engineering technique that mainly aims to steal personal or confidential data and may harm the target individual or organization in many ways. In phishing, fraudsters hide their identity as legitimate people, banks, or institutions, whether governmental or private (Alattas et al., 2022). Phishing is an increasing threat that causes billions in losses and damage to productivity, trade secrets, and reputations each year. (Jensen et al., 2022). Phishing is a well-known cybersecurity attack that has rapidly increased in recent years. It poses risks to businesses, government agencies and all users due to sensitive data breaches and subsequent financial losses. Das et al., 2022).

2 Methods

For the investigation of the social engineering issue, an organization- a health care facility that provides diagnostic and health care services was selected. The health facility employs 30 specialist doctors, 50 nurses and 25 other service personnel. The content of the testing will be the resilience of the administrative staff of the selected healthcare facility to an email phishing attack. The test results will be anonymous to maintain appropriate respondent confidentiality and reputation. The test will be conducted in multiple phases to be gone through in a phased manner.

2.1 Test planning

Planning was the initial stage of the email phishing test, when it was agreed that some statistical analysis should be done on the number of respondents who were not attentive enough and fell into the trap. Given the relatively high technical skill and work focus of the administrative staff in the security sector, it was assessed that the phishing email created would be very plausible, both in terms of the sender and the content of the message sent. A real attacker would use the information obtained for extortion, misuse of sensitive data.... The main point already during the planning was that no information obtained should be leaked, therefore no names, titles or other personal characteristics will be mentioned further.

2.2 Establishing hypotheses

Prior to conducting the phishing test, the following hypotheses were established to serve as an estimate of the process and to anticipate a certain vision of the outcome.

Hypothesis 1: No one of the recipients of the phishing email will get caught and send any response.

Hypothesis 2: Less than 20% of the recipients of the phishing mail will succumb.

Hypothesis 3: More than 20% of the recipients of the phishing mail will succumb.

2.3 Test preparation

In the test preparation phase, the necessary technical and tactical steps were taken to create and run the test, creating a test that consisted of faking an attack and determining how many healthcare facility administrators would believe the attack to be true. It started with selecting a person who would be trustworthy enough for the interviewees to believe and respond.

Selecting the person the attacker would impersonate in the test was followed by identifying certain behavior patterns of that person, the message must look as convincing as possible. In order to create a phishing email, it is necessary to observe real messages from a genuine information system administrator and notice their details (Sarno et al., 2022).

The next step was to observe how the administrator expresses himself in the text, how he introduces himself and how he ends the message. It was found that generally in formal messages the administrator introduces himself with the greeting "Hello." This is followed by the content of the message, which tends to be short and to the point, and the message ends with a thank you (Thank you) together with the signature of the administrator's name and surname. From this information, it was possible to construct a fake phishing email message.

The next step was to create(purchase) an Internet domain through which the emails were sent. In the emails, the trusted person asked the administrative staff of the healthcare facility to send access data (password and login) to the system used in the healthcare facility.

2.4. Running the test

The official launch of the phishing test took place on June 22, 2022 in the premises of the medical facility. Using crafted login credentials, a fake attacker was able to access a trusted person's email account and begin crafting the content of a message that was sent out to administrative staff. The crafted message did not contain any grammatical errors or hyperlinks that would be suspicious to the user. The conclusion of all these measures is a message with almost no error, from a trusted person and therefore the administrative staff succumbed to a staged attack.

3 Results

26 out of 105 respondents responded to the phishing message, which is 25%. However, this number does not represent the number of unwanted intrusions into the system, only the response to the mail. It is not possible to clearly assess the security threat from it. The results are shown in Table 1.

Table 1. Responses to a phishing email.

	They responded without providing a password	**They responded with providing the password**	**They did not respond**	**Total**
Specialist doctors	4	6	20	**30**
Nurses	5	6	39	**50**
Other service personnel	2	3	20	**25**
Total	**11**	**15**	**79**	**105**

Source: authors (2022)

It follows from the conducted test that 26 employees involved in the testing responded to the phishing email:

- 11 employees employees who erred by replying to the message but not sending their password,
- 15 became a victim of phishing and provided their password,
- 79 without an answer, following the rules of information security in the field of social engineering, responded correctly.

Respondents can be divided into three categories based on their reaction to the phishing email.

1. The first category consists of respondents who were aware of the threat but for their own reasons decided to reply to the email. A message that is suspected to be inauthentic and may contain means to compromise data is never replied to. The main reason for this is to maintain anonymity, the attacker does not know if the email has been delivered and is therefore in a state of uncertainty, but when he gets a reply, even by foolishness, he gets confirmation of the existence of the email account and can start preparing for a targeted cyber attack in some modified form, for example social engineering- spear phishing.
2. Respondents who have provided a password - have fallen victim to phishing and need to be more vigilant
3. Respondents with no response - who knew it was phishing and responded correctly.

In addition to the basic differentials of responders and non-responders, respondents invented themselves in other ways. After receiving the phishing email, they directly contacted the person of the real information system administrator. This person was at the respondents' workplace at the faculty of security engineering mostly from 10:00 to 11:00 am. These respondents took advantage of this time. One went to see him personally and asked if the mail he received was genuine and to give him the data. The other respondent sent the name and password to the email of the real administrator. The first one did the right thing and contacted the person the attacker was claiming to be and got important additional information from him. Although the second respondent did not cause a security hole in the system, as the confidentiality of the true administrator is assumed to be maintained, he should not have sent

his login details to him either. Individuals have access to the information system in their own name; it is their calling card, as it were, their personal data.

4 Discussion

The obtained results are based on the established hypotheses and obtained statistical results. Hypothesis number 3 was confirmed by the phishing test - more than 20% of the respondents succumb to phishing emails. In this sample of respondents, more than a fifth of the respondents were compromised, which cannot remain like this in the future. It is too big an intrusion into the organization's information system, which could discredit the whole organization. A project containing the possibilities of increasing organizational and technical awareness in the field of social engineering will be devoted to preventing the repetition of such an unfavorable result.

The direct conclusions from the phishing test are:

- 26 respondents out of a total of 105 failed, which represents 25%.
- Of these 26, 11 responded with their name and password, allowing the attackers access to the system.
- 5 answered without providing a password.

5 Conclusion

This paper describes social engineering in the context of an organization's cybersecurity, as a factor that is increasingly being used to penetrate organizations' information systems. The most commonly used method of social engineering is the phishing attack, in which the perpetrator poses as a trusted person and steals information (Yeoh et al., 2022). Based on the frequency and effectiveness of this type of social engineering, a test was created that consisted of faking an attack and determining how many administrative staff at a healthcare facility would succumb to the attack. Specifically, the results revealed that 26 employees, out of the 105 surveyed, failed the test and succumbed to the attacker's intent, representing 25%. Of these, 11 provided the attacker with a password and therefore access to the information system. Such a intrusion could be catastrophic for the organisation. In terms of timing, most responses came in the first few hours, indicating the spread of information about the suspicious message among employees. The results of this test demonstrated the timeliness and scope of social engineering and the need to put measures in place to help the organization be more resilient to attacks of this type. These are primarily technical measures to help improve the overall security of the information system and educational measures to educate employees.

Differences in stakeholder expectations of interest in service offerings during COVID-19 in electrical engineering companies

Lucie Kaňovská[1,*], and *Veronika* Bumberová[1]

[1]Brno University of Technology, Faculty of Business and Management, Czech Republic

Abstract

Research background: One of the options for maintaining a market position may be an emphasis on accompanying services, including smart services which, thanks to the limitations of COVID-19, could significantly alleviate the situation. However, in view of the evolving market situation, there is a general decline in the development of demand for standard products, as well as innovation and the cessation of investment in development projects. Nevertheless, there are companies that believe in renewal and increased interest in smart services from both management, customers and competitors.

Purpose of the article: The purpose of this paper is to find out the differences in stakeholders' expectations of interest in the service offering during COVID-19 in electrical engineering companies and whether these differences, if any, are significant in terms of size, market orientation, and industry focus.

Methods: This paper draws on a conjunctural research approach via a quantitative survey collected in electrical engineering companies during the coronavirus pandemic.

Findings and value added: The survey shows that expected results according to the CZ-NACE classification and size category does not prove the significance of the differences. Pessimism in the offering of complex solutions and smart services is generally lower compared to other categories. In terms of market orientation, there is no optimism about the increase in demand from final consumers, although it is different in the case of distributors. The company whose partners are intermediaries expect increased interest from customers, but they cannot determine the estimate of the steps taken by the competition, especially in the area of offering complex solutions. Increased interest in focusing on the B2B market is expected by companies, especially in the area of smart services on offer by competitors, but they do not expect a sharp increase from customers.

1 Introduction

This paper focuses on the area of service offerings provided by manufacturers to their customers. Today, services provided by manufacturers are an integral part of their offering of tangible products as well. Their offerings can be very varied, from basic to advanced services and complex solutions. In addition, nowadays, thanks to smart technologies, companies can also provide services that use these smart technologies. However, how has the situation with the provision of services changed thanks to the pandemic? Is the interest in their offering and provision among customers, company management or competitors higher? The purpose of this paper is to find out the differences in stakeholder expectations of interest in the service offering during COVID-19 in electrical engineering companies. It could be assumed that the interest in providing services to manufacturers has increased, especially for smart services. The services provided remotely could be a suitable solution during the pandemic, when it was not possible to travel and resolve repairs directly with customers. Therefore, the contribution of this paper is to unveil the changes in expectations caused by a totally new situation, in this case, the COVID-19 pandemic in the field of service offering in manufacturing companies.

The paper is structured as follows. Chapter 1 describes the service offering provided by manufacturing companies, the importance of servitization and smart technologies in the time of the COVID-19 crisis and the stakeholder approach. Chapter 2 presents the methods used in the empirical study. Chapter 3 describes the main findings and discussion related to the aim of the paper. Chapter 4 summarises the conclusions of the paper.

1.1 Service offering provided by manufacturing companies

Most manufacturers today offer services alongside their products (accompanying services), from the basic to the advanced. Basic services care about product functionality, such as pre- and post-sale services). Advanced services try to avert product breakdowns by using e.g., preventive maintenance processes, training, and maintenance contracts. Moreover, advanced services help to create value with customers up to a service business model (Kindström, 2010). Based on Fischer et al. (2012), the expansion of accompanying service offerings includes three service categories: a) customer services, b) product-related services and c) services supporting business needs. Basic and advanced services can be included in the second category as product-related services. Also, a complex solution is a possibility of service offering, where end-users are not required to deal with technical issues related to the product, because everything is organised by the supplier, e.g. regular inspections, repairs, and ensured for the general trouble-free operation of the product. Smart technologies can be a part of accompanying services also. Services using smart technologies are commonly termed as smart services. They include remote monitoring, remote diagnostics, remote repair, predictive maintenance, etc. Smart technologies are a keystone for current manufacturers, which present a new service, but they are also a catalyst for product innovation (Blichfeldt and Faullant, 2021).

Based on Grubic and Peppard (2016) a main principle of smart services is a combination of software and hardware technologies. This combination ensures the collection of remote performance data and information about the use of the product to monitor and control its current and predictive status. Suppatvech et al. (2019) recapitulate many possibilities of using smart technologies in services based on the available literature, such as remote monitoring and reporting of information in real time, monitoring of customer behaviour in use, enabling responsive and proactive maintenance, support of optimisation and remote control of operations, as well as autonomous management.

1.2 Importance of servitization and smart technologies in time of COVID-19 crisis

Based on Brax and Visintin (2017) servitization is perceived as a process of change, where manufacturers intentionally or thanks to growing trends introduce elements of services into their business models. Servitization is seen as a possible transformation process in which a company moves from a product-centric system to a service-centric system (Kohtamäki et al., 2021). Servitization and smart technologies could represent the main drivers within the current turbulent period caused by the COVID-19 outbreak (Kowalkowski et al., 2022), in which manufacturers must innovate their products (Netz et al., 2022) to sustain their businesses (Ding and Li, 2021). Servitization connected to smart technologies is called smart servitization.

COVID-19 has dramatically affected the global economy and mostly SMEs. The most threatening for companies was the increased risk connected to market contraction and financial and resource constraints (Juergensen et al., 2020). Market uncertainty saw an upsurge in the adoption of advanced technologies in the short term (Prause, 2019). This adoption helps a company's innovation performance (Usai et al., 2021), which generates opportunities to quickly adapt to the changes that have appeared because of the coronavirus disease pandemic (Paiola and Gebauer, 2020).

Servitization and smart technologies are meant as a means of proactively speeding up and applying the response to the COVID-19 crisis (Rapuccini et al., 2020). Firms which proved most impermeable to the effects of the pandemic were those which got out in front with regard to servitization and smart technologies (Rapuccini et al., 2020). Less economic damage was endured by companies in the industrial sector which enhanced their digitally enabled service growth with parallel services based on software. (Rapaccini et al., 2020).

1.3 Stakeholder approach

A stakeholder is any individual, group or even organisation that has an influence or is influenced by the company's vision, mission and strategic results and performance of the company. We divided them into internal (owner, management, employees) and external (suppliers, customers, competitors, or government, media, and others). Significant stakeholders and their abilities have an influence and share in the competitiveness, profitability, and survival of the organisation (Hanson et al., 2017). Top management and company executives have a unique position among stakeholders. They have a responsibility for the direction and operation of the company and, as a result, also the greatest overview of events inside and outside the company. These stakeholders (top management and company executives) also decide what and whose priorities and needs the company will meet, and thus determine what the relationship with other stakeholders will be. Thanks to this unique position, they are one of the most influential stakeholders. However, mastering the correctness of relationships with all stakeholders is a source of long-term competitive advantage (Monkevičienė and Rybakovas, 2003).

Compliance of the expectations and goals of the most important stakeholders with the implementation of the strategy is a key success factor. Interest groups whose expectations, interests and goals are essential not to be overlooked include the owner, top management and managers, or creditors and business partners (Fotr et al., 2017). When selecting significant internal stakeholders for analysis (research), it is appropriate to know the corporate environment and culture. Based on this self-involvement, it is then possible to identify influential people. This influence may be based on their formal position, but it can also be trustworthy individuals who have been in the business for a long time, have experience and know how the business works (Hindle, 2010).

2 Research sample and methods

Sections CZ-NACE 26 (Manufacture of computer, electronic and optical products) and CZ-NACE 27 (Manufacture of electrical equipment) from the classification of economic activities designated by the European Commission were chosen in order to facilitate the processing of empirical research. CZ-NACE 26 firms, i.e., from electronics and electrical engineering, operate as subcontractors for, e.g. the car sector and mechanical engineering and numerous other fields of the economy. Labour-intensive production and the hugely efficient automated production sectors also form part of this group. Section CZ-NACE 27 relates to sectors within the manufacturing industry with more long-term significance, which hold a very powerful role in the economy and offer a vast selection of products. The competitiveness of other fields of the manufacturing industry and energy depends on the type of products from within the electrical engineering industry. This sector can be counted as one of the most significant manufacturing sector employers (MPO, 2017).

The web-based questionnaire was emailed to mainly directors and managers, who were asked to complete it. 55 responses were received which were deemed to be correctly and fully filled in. Table 1 shows the nature of respondents in relation to selected characteristics.

In terms of size, measured by number of employees, there are 40% micro and small enterprises, 21.8% medium sized enterprises and 18.2% large enterprises in the total sample. We had to exclude from the further analysis of mean differences a total of 20% of respondents in the number unknown category. The predominant customers in terms of profit share are: 21.8% focused on the B2C market, 54.5% on the B2B market and 23.6% focused on distributors (see Table 1).

Table 1. The structure of respondents according to CZ-NACE

	Frequency	Percent	Valid Percent	Cumulative Percent
CZ NACE 26	18	32.7	32.7	32.7
CZ NACE 27	37	67.3	67.3	100.0
Micro and small enterprises (0 – 49)	22	40.0	50.0	50.0
Medium sized enterprises (50 – 249)	12	21.8	27.3	77.3
Large enterprises (≥ 250)	10	18.2	22.7	100.0
Unknown category (re no. of employees)	11	20.0	-	-
The end-user B2C market	12	21.8	21.8	21.8
Manufactures or other firms, B2B market	30	54.5	54.5	76.4
Distributors (distribution channels)	13	23.6	23.6	100.0
Total	*55*	*100.0*	*100.0*

2.1 Research strategy and methods

This paper draws on the data obtained from the quantitative survey. The survey was carried out in September 2020. The number of respondents was rather low due to the unfortunately timed launch of the research. When the research was commissioned in the summer months of 2020, the end of the pandemic was expected. However, when the questionnaire was implemented in September 2020, another wave of COVID-19 arrived. Manufacturers at that time did not have much time and desire to fill in the questionnaire, so the result of 55 respondents is certainly a success.

Originally, a 5-point scale was applied for gathering data from respondents about expectations of increased interest of their customers, management, and competitors in individual types of services (1-totally agree, 2 – partially agree, 3 – partially disagree, 4 –

totally disagree, -1 - without estimate/don't know). We excluded "no answer" due to the absence of business activity for further evaluation from respondents. Further, the analysis needed the recording of the original data into modification: agree and partially agree as "YES" (1), partially disagree or total disagree as "NO" (2), without estimate/don't know (-1) for better evaluation of result outputs. For a deeper analysis of differences according to size, field and orientation in the customer market, nonparametric tests were performed to compare the differences in mean (average score) of the results. Spider graphs were chosen to visually represent the results.

3 Results and discussion

The overall perception of interest within selected stakeholder categories and the offering of services and solutions is shown in the following Figure 1. As can be seen, about 25% of companies expect growth, 25% cannot estimate the situation, but 45% of companies don't expect growth. Pessimism in the offering of complex solutions and smart services is generally lower compared to other categories. Despite the difficult situation, manufacturers did not lose optimism to a great extent, but it must be acknowledged in the marginal answers of respondents that it is almost half and half, and that rather expectations of stagnation/decline and uncertainty from the development in basic services and the related decline in other related solutions prevail, especially for customers. At a time when the market situation cannot be read, business partners do not make very strategic decisions about new orders, projects, or new suppliers.
Figure 1. Overall expectations of growing interest according to selected stakeholders

Source: Kaňovská and Bumberová (2022)

The results in the area of testing are shown in the following Table 2, as expected according to the economic classification CZ-NACE, which does not prove the significance of the differences. Figure 2 shows a greater pessimism, which prevails in the production of electrical equipment in general (CZ-NACE 27). However, it is a specific sector, where these categories of companies are often not primarily oriented on the provision of services. Servitization is often not possible for these types of companies, and they do not even plan to develop activities in this direction. What little could be considered as servitization is not in

any way dependent on the crisis nor does it affect their results. The same situation is also for smart services. On the other hand, manufacturers from CZ-NACE 26 often offer additional services such as equipment repairs (service providers as intermediaries are their customers), and they are still seeing an increasing interest in smart services. They have information from intermediaries that end customers think more about investments and put more emphasis on maintaining and maximising the life of technology than in the period before COVID-19.

Table 2. Mann-Whitney U test[a]

Type of services	Grouping variable: CZ-NACE			
	Mann-Whitney U	Wilcoxon W	Z	Sig. a
Basic services	173.000	638.000	-1.015	0.310
Advanced services	253.500	389.500	-0.245	0.807
Complex services	240.000	376.000	-0.564	0.573
Smart services	249.500	385.500	-0.334	0.739

a Asymp. Sig. (2-tailed), * Sig.≤ 0.05, ** Sig.≤ 0.01.

Source: Kaňovská and Bumberová (2022)
Figure 2. Average score expectations according to CZ-NACE

Source: Kaňovská and Bumberová (2022)

The results in the area of testing by expectations according to size specifics and market orientation are shown in Table 3. No significant dependence was demonstrated for the size category of enterprises, but Figure 3 shows that micro and small enterprises are more optimistic than medium-sized companies, which focus on the offer of advanced services, which recorded the highest level of basic services together with basic services, pessimism in terms of increased interest from customers. Micro and small companies have adapted to the

new conditions by far the most, thanks to their flexibility and having less capital tied up, or their focus on less complex contracts.

Table 3. Kruskal–Wallis Test[a]

Grouping variable: no. of employees			
Type of services	Customers	Management	Competitors
Basic services	0.810	0.872	0.888
Advanced services	0.860	0.867	0.198
Complex services	0.305	0.912	0.400
Smart services	0.184	0.191	0.386
Grouping variable: focus market			
Basic services	0.028*	0.014*	0.605
Advanced services	0.229	0.016*	0.256
Complex services	0.007**	0.043**	0.100
Smart services	0.050**	0.003**	0.228

a Asymp. Sig. (2-tailed), * Sig.$\leq$ 0.05, ** Sig.$\leq$ 0.01.

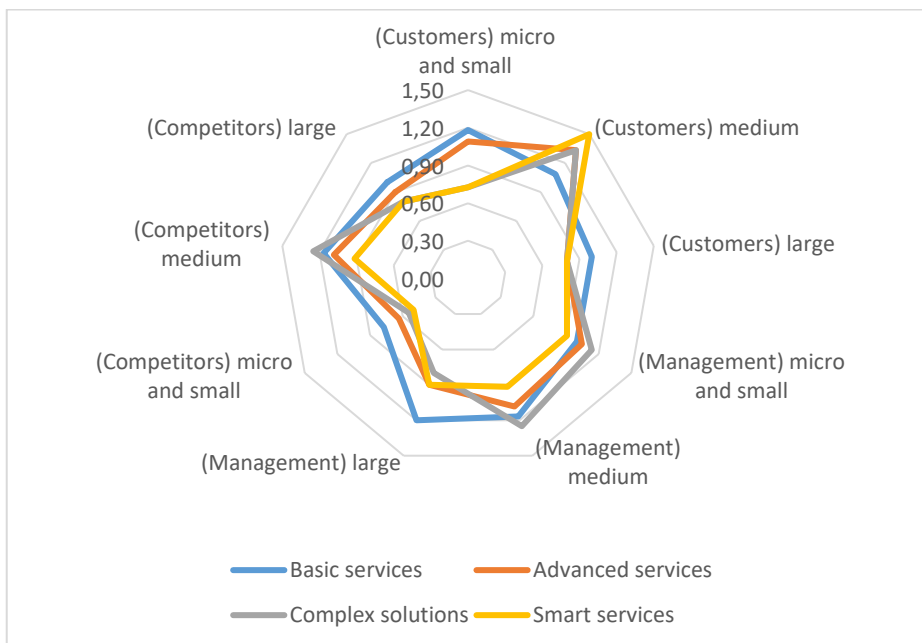
Source: Kaňovská and Bumberová (2022)


Figure 3. Average score expectations according to enterprise size

Source: Kaňovská and Bumberová (2022)

In terms of market orientation, there are already differences that are influenced by the specifics of the sales market of companies and final consumers. While there is no optimism about the increase in demand from final consumers (B2C market), it is different in the case of distributors. The companies whose partners are intermediaries expect increased interest from customers, but they cannot determine the estimate of the steps taken by the competition, especially in the area of offering complex solutions. This also applies in the case of management's awareness and positive expectations.

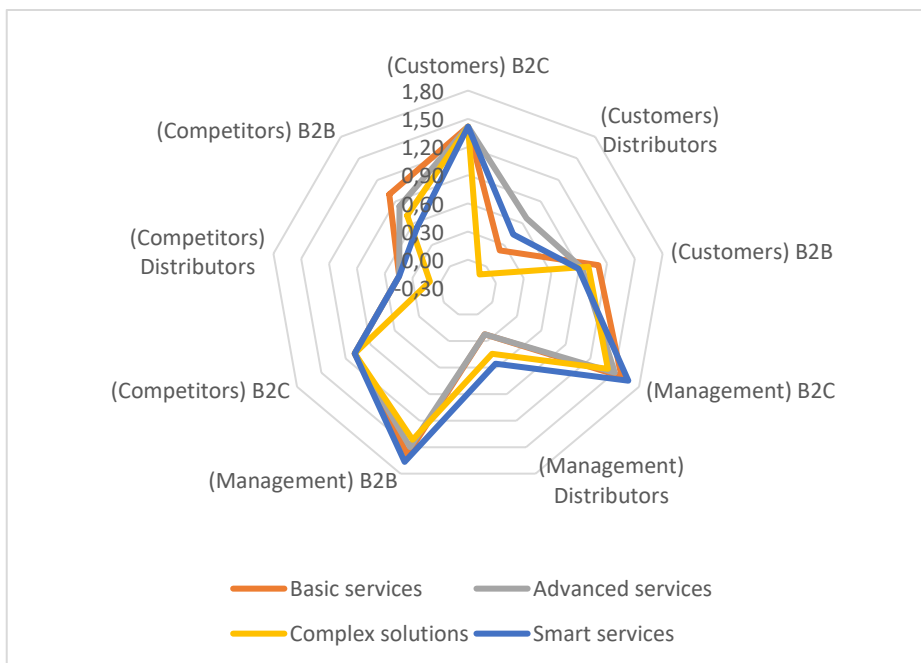
Due to increased interest in focusing on the B2B markets, companies expect higher expectations especially in the area of smart services by their competitors, However, they do not expect a sharp increase from customers or they are not even able to estimate the demand for services. The highest level of pessimism on the part of management is then confirmed by companies in the inter-company market and the purely manufacturing industry (with minimum of servitization). This confirms the fact that the rudder of change is the most difficult to turn there, also due to the search for new outlets for new products. On the other hand, this segment sometimes has the advantage of inertia (see the Figure 4).


Figure 4. Average score expectations according to market orientation

Source: Kaňovská and Bumberová (2022)

4 Conclusion

For some manufacturers, covid has become destructive, but for some, on the contrary, it has become an attractive opportunity to move forward in some areas and gain a competitive advantage. During the pandemic, it was impossible to meet with customers and distributors, which could lead to an increase in stakeholders' interest in service offering, especially in the area of advanced services, such as smart services. Therefore, the aim of this paper was to find out the differences in stakeholders' expectations of interest in the service offering during COVID-19 in electrical engineering companies. The results of the paper did not prove the significance of the differences according to the CZ-NACE classification and size category. Pessimism in the offering of complex solutions and smart services is generally lower compared to other categories. In terms of market orientation, there is no optimism about the increase in demand from final consumers, it is different in the case of distributors.

The companies whose partners are intermediaries expect increased interest from customers, but they cannot determine the estimate of the steps taken by the competition, especially in the area of offering complex solutions. Increased interest in focusing on the B2B

market is expected by companies, especially in the area of smart services on offer by competitors, but they do not expect a sharp increase from customers. The contribution of this paper was to unveil the changes in expectations caused by a totally new situation, in this case, the COVID-19 pandemic in the field of service offering in manufacturing companies.

Abstract

Research background: Economic inputs and outputs of the national economy are significantly influenced by foreign trade. Even globally important players in international trade are going through turbulent changes due to the influence of new factors affecting foreign trade relations.
Purpose of the article: The subject of analysis is the foreign trade of the selected countries in the Central European region. The aim of the article is to contribute to the discussion about the impact of countries' participation in international trade on the development of their socio-economic environment.
Methods: Data collection and analysis, comparative analysis, foreign trade indexes, deduction and induction.
Findings & Value added: The interdependence of the markets of the analysed countries is high, and even if the openness of their economies fluctuates, they do not avoid the rapid influence of factors that significantly affect global markets. Smaller monitored countries are significantly affected by them, but Poland has a higher strength of the internal market, which somewhat mitigates the speed and strength of the impact of global factors on its socio-economic environment. The reactions of national governments to the pandemic caused restrictions on the cross-border mobility of people (including labour mobility), affected the global supply chain (production and distribution capacities), and changed supply and demand patterns. It accelerated changes in the integration economic groups (especially the EU), but also the emergence of a new paradigm in global trade. The war conflict (and subsequent economic sanctions) comprehensively rewrite not only the foreign trade policy of countries but also geopolitics as such.

1 Introduction

The economic situation of countries is influenced by a number of different factors. The importance of each factor varies from country to country, and what is important for one country may be completely irrelevant for another. Nevertheless, it is necessary to identify general trends and patterns that have a great impact on the economic development of individual countries. The economies of European countries have tended to develop up to 2020 (Aliukov and Buleca, 2022). The COVID-19 pandemic brought great uncertainty to markets in 2020, and both production and consumption were subject to rapid and extreme fluctuations. European Union was among the most affected economies, with a drop in GDP by 6.3% in 2020 (Kejžar et al., 2022). The COVID-19 pandemic has brought a huge recession to the EU, which could increase inequalities between regions. As a result of the decrease in demand and production, the global economy entered a recession in spring 2020. The year 2020 witnessed the biggest drop in global economic growth since the Great Depression of the 1930s (Li et al., 2022). Supply chains were disrupted, and millions of people lost their jobs as a result of the pandemic. Government interventions caused the closure of most businesses to reduce the risk of infection. Despite this, a number of negative impacts on the population have been observed. Many people became infected or had to be isolated in quarantine, and some countries suffered high mortality rates. The economic recession, high unemployment, serious income losses, liquidity problems, as well as the closure of hotels and restaurants and the cessation of air and bus transportation have led to an overall decline in demand in various sectors of the economy, but especially for tourism (Plzáková and Smeral, 2022; Martín-Domingo and Martín, 2022).

In 2020, the combined gross domestic product (GDP) of the European Union was just over €13.3 trillion. Europe's share of global GDP was just under 15 % that year, and this share is expected to fall to 13.99 % by 2026. Europe's declining share of the global economy is a long-term trend and is related to the fact that European economies are growing more slowly than those in other parts of the world, such as Asia and especially China. With a GDP of more than €3.3 trillion, Germany has the largest economy in Europe, while France and the United Kingdom have the second and third largest economies. However, none of these three countries grew at all in 2020, with almost all European nations experiencing negative growth rates in 2020 because of the coronavirus pandemic (Clark, 2022). At a time when it was thought that the pandemic was diminishing and that the market would recover from its influence, there was a conflict between Russia and Ukraine as well as sanctions as a result which greatly affected the global economy. The war conflict in Ukraine has significantly affected the EU economy, pushing the EU towards lower growth and higher inflation (Prohorovs, 2022). Global inflationary pressures, or erosion of household purchasing power, have been supported in particular by rapid increases in energy and food commodity prices (European Commission 2022). The war conflict in Ukraine as well as sanctions will have broad implications for the global business landscape as well. As a producer of 11% of global oil and home to 25% of the world's natural gas reserves, Russia will continue to impact energy markets (Markus, 2022). Overall, real GDP is forecast to grow by 2.7% in 2022 and 1.5% in 2023 in the EU and by 2.6% in 2022 and 1.4% in 2023 the Euro area. The projected annual growth rate for this year is propped up by the momentum gathered with the recovery of last year and a stronger first quarter than previously estimated (European Commission, 2022). Global economic growth is projected to slow from 6.1% in 2021 to 3.6% in 2022 and 2023. This is 0.8 and 0.2 percentage points lower than projected in January for 2022 and 2023 (Irtyshcheva et al., 2022).

International studies have shown relationships between the coronavirus crisis and feelings of job insecurity (Maleki et al., 2021; Karacsony et al., 2022). Feelings of insecurity were affected by fears of losing their jobs, as workers with higher levels of redundancy due to the

coronavirus crisis also had higher feelings of insecurity (Lippert et al., 2021; Giorgi et al., 2020). The financial shock caused by the pandemic weakened the financial security of households regardless of the income level of households (Szustak et al., 2021). Because of the uncertainty and fear of the virus, some studies (Karacsony et al., 2022) predicted less spending of households and consequently lower ability of the economies to reach the previous level of development. It did not happen in full. Szustak et al. (2021) studied the Consumer Confidence Index (CCI) of V4 countries within the years 2018-2021. The future was perceived as highly uncertain during the COVID pandemic. The CCI has fallen in three of the four analysed countries (except Hungary).

2 Methods

In addition to the traditional V4 comparative format (Slovakia, Czech Republic, Poland and Hungary), we also included Slovenia in the analyses, as a country with a smaller population than Slovakia (and at the same time all other analysed countries) but belonging to the Eurozone (since 2007 - even before the entry of Slovakia into it). We have thus expanded the analytical basis for evaluating the development in Slovakia.

The development of international trade over the last ten years, i.e. the period 2012-2021, was analysed. Data on international trade balance published by Eurostat and the national statistical offices of the monitored countries were used in the analyses. Specifically:
-    Czechia: Czech Statistical Office
-    Hungary: Hungarian Central Statistical Office
-    Poland: Statistics Poland
-    Slovakia: Statistical Office of the Slovak Republic
-    Slovenia: Statistical Office of the Republic of Slovenia

In the process of data collection, we notice significant differences in the data provided by institutions processing trade statistics (both international and national). The differences between values of international trade in accessed databases result from the application of a different methodology of data collection and calculation of indicators, as well as differences in terminology. Eurostat database consist of two systems: Intrastat and Extrastat. Intrastat as a data collection system is closely linked to VAT systems since single EU market removed customs formalities between EU Member States what resulted in a loss of information. On the other hand, Extrastat record flows of goods between the EU and third countries. This system uses Extra-EU statistics gathered by customs authorities. Regarding methodology: In the International trade in goods section of the Eurostat database, Eurostat presents data purely on cross-border movements of goods, which may not be consistent with the change of ownership data. CZSO (2022) discusses the topic of differences in the data of registered movement of goods in international trade in more detail. In order to be able to compare country data, we used the Eurostat methodology. Thus, in case of Czechia, data were retrieved as Cross-border movements of goods (CBmG).

3 Results

The development of the balance of the trade balance of the compared countries is evident from Graph 1. Table 1 provides an overview of specific values in the monitored period.

Table 1. International Trade Balance (in mil. Euro)..

	2012	2013	2014	2015	2016	2017	2018	2019	2020	2021
Czechia	12166	13564	15597	14883	17732	16793	14864	17963	18118	12259

Figure 1. International Trade Balance (in mil. Euro).

Source: Own elaboration based on Statistical Office of the Slovak Republic (2022), Hungarian Central Statistical Office (2022), Czech Statistical Office (2022), Statistics Poland (2022), and Statistical Office of the Republic of Slovenia (2022).

Poland has a significant service sector, which accounts for over 55% of GDP (Statista, 2022). According to statistics (Statistics Poland, 2022), industry, mining and agriculture are also significant. Poland is the third largest agricultural region of the EU and Polish farmers have considerable bargaining power in the public debate on the use of agricultural land in Poland. Poland's largest trading partner in terms of imports and exports is Germany, followed by the UK, the Czech Republic, France, and the Netherlands. The engineering industry makes up the largest share (38%) of Polish exports. Import partners are Germany, China, Italy, the Netherlands, and the Czech Republic. It is followed by the chemical industry (mainly drugs and pharmaceuticals) and agriculture with the food industry (mainly the meat sector). The territorial structure of the international trade of Poland and Slovakia is similar - the largest exchange sessions are carried out with the same partners. The volume differences in trade are of course large. In addition, Poland has a very strongly developed domestic market. Its strength helps it better overcome sudden changes in world markets.

Slovenia is also an export-oriented economy due to its small domestic market. The openness of the economy makes it largely dependent on global trends and developments in partner markets, of which the markets of the EU states are important - up to 70% of Slovenian exports (Statistical Office of the Republic of Slovenia, 2022). The most important is

Germany, followed by Italy, Switzerland, Croatia, Austria, and also the V4 countries. The first three countries are also important for the import of goods. The Slovenian market is highly competitive and dynamically developing with a focus on industries with high added value. Medicines (packaged medicines), cars and their components and refined oil contribute the most in terms of value to the total export.

For the **Czechia**, as in the case of other countries, Germany is the most important trading partner. Among the Central European countries, Slovakia and Poland are also important for Czech exports. Import values are formed mainly in trade with Germany, China and Poland. The main traded commodities are machinery, electrical equipment and vehicles and their components. The significance of the EU's internal market is very significant for Czechia. According to Eurostat (2022), in 2021, the highest shares of intra-EU trade in goods (above 75 % of total trade) were recorded for Luxembourg (85.8 %), Slovakia (79.3 %) and Czechia (77.2 %) with this ratio falling to 52.2 % for Greece and 38.1 % for Ireland.

Hungary exported the most electrical equipment (year 2021). Germany was also the largest trading partner (export of electric accumulators), followed by Italy and Romania. As the only country from the V4 group, its exports are not territorially focused on any of the other countries of the Visegrad Four (in the first three highest export values). Goods are imported from Germany, China (mainly electronic devices for both) and Austria (mineral fuels and oils).

4 Conclusions

Economic inputs and outputs of the national economy are significantly influenced by foreign trade. Even globally important players in international trade are going through turbulent changes due to the influence of new factors affecting foreign trade relations. The impact of the Covid-19 pandemic was significantly negative in the subsequent economic development of the monitored countries. From the moment of its outbreak, it paralyzed the world economy with its consequences in the form of restrictive measures by the governments of the affected countries. The first major factor was the shutdown of the production of Chinese factories, which crippled the global supply chain with chain consequences on all connected markets. The fragility of the global supply chain was also demonstrated by the consequences of the 2021 Suez Canal collision, where a six-day blockade by the container ship Ever Given influenced global trade with long-lasting consequences.

In the last three years, Slovakia's GDP per capita in purchasing power parity is lower than in the Czech Republic, Slovenia and Poland (which even has a lower average annual wage during this period) (Trading Economics, 2022). In comparison with the largest (Poland) and the smallest (Slovenia) monitored economy, Slovakia achieves a worse ranking from the point of view of the Global Competitiveness Index (GCI) and Doing business (DB) (WEC, 2022; WorldBank, 2020) The industry had the greatest negative impact on the DB index starting a business and dealing with building permits. A high level of bureaucracy plays a role in both evaluated items. Among the analysed countries, only Slovakia and Slovenia are members of the Eurozone. The advantage of this is mainly simplified trading at the international level and currency stability (in terms of exchange rate risks). The disadvantage is frequent price increases or the growth of prices (not only of consumer prices but also of inputs for the corporate sector) and greater dependence of the national state on the policy of the European Central Bank.

Exclusively from an economic point of view, it can be stated that the analysed economies recorded progress in the monitored period. This can also be argued based on how quickly business recovered in the post-pandemic period. It is questionable whether economic progress does not paradoxically raise environmental questions, and to what extent it affects

the positive development of countries in the social field. The future development of the Central European region will be influenced mainly by factors that are difficult to predict: the global management of the pandemic, the ongoing war conflict in Ukraine (with all its consequences), political decisions at the level of national states and at the level of the European Union (including decisions regarding energy security).

Increasing the prevention of financial crises in the enterprise using scenario analysis - a case study

Peter Kardoš[1,*], and *Mária* Hudáková[1]

[1] University of Zilina, Faculty of Security Engineering, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: External threats in the global environment and the resulting economic consequences, e.g. the COVID-19 pandemic, the war in Ukraine, the rise in energy prices, and rising inflation make corporates give more attention to the prevention of crises. Since some negative events are less predictable, the need for greater preparedness and associated risk assessment using various methods and techniques, e.g. scenario analysis, is in place.

Purpose of the article: Is to present the results of a case study focused on managing a service enterprise during a financial crisis using scenario analysis in order to prevent the bankruptcy. Part of the goal is to increase the awareness of business managers about prevention and preparedness for negative events using the method of scenario analysis.

Methods: To achieve the set goal, methods are used, e.g. analysis of relevant sources, studies, surveys, authors' own experiences, analysis of scenarios, investigation, comparison, and assessment of current knowledge and approaches of experts from practice and academia.

Findings & Value added: The results of this case study in a specific service enterprise point to the need to pay attention to scenario analysis, with the help of which the enterprise can think about the future development, possible economic consequences, and can take appropriate measures to avoid a crisis or bankruptcy. Processed results benefit board members, key process managers, risk experts, regulators, etc. not only in the business sector but also in the public sector in Slovakia and other countries in the world.

Keywords: *crisis, scenario analysis, prevention, consequences, enterprise*

JEL Classification: *L26, M21, G32, L52*

1 Introduction

In the current unpredictable and uncertain global environment, the consequences of the covid-19 pandemic are still fading and other threats are already coming, such as war in Ukraine, energy crisis, rising inflation, etc. The mentioned uncertainty emphasizes **the increase of resistance and the need for prevention in the enterprise** (Fraser and Simkins,

---

* Corresponding author: peter.kardos@prims.sk

2016; Gates at el., 2012). One option is the application of risk management, in an effort to be better prepared for crisis situations or prevent enterprise crises. The results of the Institute of Risk Management shows that every year the international interest in risk management in any governmental, public and business sphere is gradually growing. Their results show that it is very important to follow the framework, processes and standards for risk management so that enterprises can reliably manage risks and fulfill strategic objectives (IRM, 2022). These conclusions are also confirmed by the results of a study by the Federation of European Risk Management Associations (FERMA, 2022), which investigated the level of fulfillment of risk management tasks in strengthening the resilience of their enterprise. The study results show that three-quarters of risk managers expect a greater emphasis in the near future to more deeply integrate resilience efforts into the strategy process. Increasing resistance and prevention must become part of strategic considerations and strategic process in the enterprise (FERMA, 2022).

At the same time, negative threats, limitations, and various problems provide space and opportunities to reevaluate policies, strategies, measures, and priorities from a long-term perspective of enterprise management (Belas et al., 2021). It should be important for managers to set a strategy to strengthen resilience and pay much more attention to assessing risks, monitoring the symptoms of enterprise crises, proposing measures to reduce them (Makka and Kampova, 2021). According to the authors (Bsoul-Kopowska, 2020; Herghiligiu, 2014), the most common symptoms of a crisis can be e.g. declining market share, declining profitability, increasing dependence on external sources, incompetent management decisions leading to poor investment decisions, faulty planning, poor diversification and many others. Some of the mentioned symptoms have an immediate direct impact on the enterprise's financial situation, others will be reflected in the enterprise's performance and financial statements in the long term (Kliestik et al., 2021). Therefore, the issue of symptoms and their early identification is very crucial (Meng, 2007).

On the one hand, there are threats from the enterprise's external environment, on the other hand, threats arising from the internal environment, which can also be the cause of enterprise crises should not be underestimated (Vermeulen et al., 2015; Brzezinski, 2011). According to the research of the American Institute for Crisis Management (2022), the cause of more than half of crises in enterprises is incorrect and ineffective problem solving by managers. Their study shows that the cause of serious business problems is in many cases the human factor, namely executive employees with their behavior, as well as managers with their wrong decisions.

One of the risk management methods that managers can use to identify risks early is **scenario analysis** (Du and Xi, 2010). Using this method, enterprises can think about the future development of the enterprise from an optimistic, pessimistic and realistic point of view. Based on thorough analysis, they can predict risks, their consequences, and propose measures to minimize anticipated changes (Dvorský at el., 2021; Area et al., 2017). When applying the method, it is necessary to take into account the quality and quantity of changes in the internal and external environment of the enterprise's development. Identifying symptoms, indicators and reacting to them should be an important part of strategic business management (Farooq et al., 2018).

The aim of the paper is to present the results of a case study focused on enterprise management during the financial crisis using scenario analysis in an attempt to prevent the bankruptcy of a specific enterprise providing services in Slovakia. Part of the goal is to increase the awareness of business managers about prevention and preparedness for negative events using the method of scenario analysis.

2 Methodology

An important methodological starting point is the assumption that frequent unpredictable changes in the external and internal environment are a source of risks and cause a much increased need for resilience and prevention in the enterprise than before. Based on this, it is possible to make the assumption that despite the negative effects of the environment, it is possible to assess risks in time and reduce the consequences of adverse situations. This is possible mainly through the effective application of risk management using methods and techniques, e.g. by analyzing scenarios. The comparison of previous knowledge and approaches to the management of risks and enterprise crises confirms the high topicality of the issue being addressed. The key methodological source is a processed own study of business management during the financial crisis using scenario analysis in an attempt to prevent the bankruptcy of a service enterprise.

The following section presents the processed results of the conducted study.

To fulfill the set goal, following methods were used:
- analysis of relevant sources, studies, current knowledge and approaches,
- analysis of the authors' own experiences from practice and from the academic environment in the form of solving scientific projects,
- scenario analysis (optimistic, realistic and pessimistic),
- cash flow analysis,
- examination and assessment of the processed results,
- synthesis of proposed measures to prevent bankruptcy and prediction of cash flow after the adoption of corrective measures.

The conducted study was processed according to the procedure of business management in crisis Klučka (2021):
1. Identification of symptoms and causes of the crisis in the enterprise
2. Analysis of scenarios and taking measures with regard to the short-term survival of the enterprise (cash flow management to overcome the crisis)
3. Taking measures with regard to the long-term development of the enterprise (defining the strategy and adopting the action plan),
4. Implementation of measures with regard to the long-term development of the enterprise (obtaining the consent of the owners, managing changes).

3 Results

The service enterprise was founded in April 2021 and began to fully function in October 2021. The main activity of the service enterprise is the maintenance of the town and its property. Due to the provision of sensitive data, the name of the enterprise has been changed. The 100% owner of the enterprise is the town, which founded the service enterprise from the maintenance department of the municipal office. Due to incorrect financing and bad decisions by the owner, the enterprise got into a financial crisis in the first quarter of 2022, which may lead to bankruptcy.

The main goal of founding the service enterprise is to perform more efficient maintenance of the town and generate profit, which will be invested in new facilities and in the improvement of urban elements - public greenery, town buildings, roads, sidewalks etc.. The owner decided that the enterprise will be a registered social enterprise, which will be aimed at employing vulnerable and disadvantaged people, given that this type of people have already worked in the maintenance department of the municipal office. For vulnerable and disadvantaged people, registered social enterprise receives wage subsidies from the Office of Social Affairs and Family. This status was obtained before fully functioning of the enterprise.

At the fully functioning of the enterprise hired all employees of the municipal office maintenance department and new employees necessary for the operation of the enterprise. The condition for the enterprise to maintain registered social enterprise status is that it must employ 30% of vulnerable or disadvantaged people, which was achieved in March 2022. The owner also decided to use the project for registered social enterprise in the form of non-refundable financial assistance, in which they are reimbursed for 18 months wages for workers up to €200,000 from the Office of Social Affairs and Family. This project involves conditions, which the enterprise must fulfill, e.g. the participation of the bank in the form of a loan for the purchase of technology and the investment of own funds in the form chosen by the enterprise. The owner together with the CEO of the enterprise decided on the purchase of a telescopic lift from a loan and a flatbed truck as a investment of own funds.

A enterprise that is owned by the public administration and also has registered social enterprise status, brings many more conditions and obligations than normal enterprises. It has its advantages as a stable partner and various subsidies that can be drawn, but also disadvantages in the form of rules that must be followed and play an important role in the planning and management of the enterprise. The enterprise must perform 80% of its activities for the town and 20% of its activities for other customers. It is therefore necessary to plan and monitor the enterprise's activities thoroughly, which is also evidenced by the fact that it was the owner's decisions during the planning phase that led the enterprise to a financial crisis.

The following section presents the processed results of a study of enterprise management during the financial crisis using scenario analysis in an attempt to prevent the bankruptcy of the service enterprise.

3.1 Identification of symptoms and causes of the crisis in the enterprise

The owner decided to finance the enterprise in 2021 in the form of a subsidy from the town and not on the basis of invoices as in the case of ordinary enterprises, he switched to invoicing from 2022. This decision resulted in the enterprise having to return all subsidies for wages for vulnerable and disadvantaged workers and for workers assigned in non-refundable financial assistance project for the months of 2021 back to the town. The reason was that the workers' wages cannot be covered by a subsidy from the town and at the same time a subsidy from the Office of Social Affairs and Family, i.e. both from public sources.

Another decision of the owner was to make a non-monetary contribution in the form of land to the share capital and finance the start of the business with the amount from the budget for the maintenance department of municipal office for the year 2021, or its equivalent for the months of September to December 2021. No financial resources were planned for the start-up of the business. The necessary resources - offices, equipment, cars, tools, etc. in order to function, town gave to the enterprise if a form of loan, which later turned out to be insufficient, it was necessary to obtain additional resources for the necessary functioning, but they had to be obtained from the budget of maintenance department of municipal office.

At the beginning of 2022, financing in the form of a town subsidy ended and invoicing started, but it had to be switched to pre-invoicing in order to be able to cover all expenses on time. In addition, since January the service enterprise has been guided by the new budget for 2022, and after accounting for the town's subsidy from 2021, it came up that the obligations from 2021 had to be covered from the budget for 2022. Another obligation was to return the all subsidies for wages from the Office of Social Affairs and Family back to the town.

From the above analysis, the following symptoms were found:
- the impossibility of invoicing for services for the town after the service has been performed as in normal business relations,

- insufficient cash for investing in infrastructure,
- insufficient financial reserves for changes in the enterprise that would lead to improved conditions and increased sales of services,
- problems with the circulation of cash flow.

The main causes were identified:
- making a non-monetary contribution in the form of a land to the share capital.
- financing of the enterprise with the amount from the budget for the maintenance department for the year 2021.
- financing of the enterprise in 2021 in the form of a town subsidy, which led to the return of the subsidy from the Office of Social Affairs and Family back to the town.

Since it is a cash flow problem, it can be concluded that the enterprise is in an **acute financial crisis**, therefore it is necessary to perform an analysis of the enterprise's financial flows and take measures to prevent bankruptcy. It is necessary to take measures to rehabilitate the enterprise.

3.2 Analysis of scenarios and taking measures with regard to the short-term survival of the enterprise

The analysis of cash flow in the enterprise was carried out from the starting of business activities, that is, from September 2021 with a prediction for the years 2022 and 2023.
The following tables show the analysis of cash flow in the current situation without future measures:

Table 2. Analysis and prediction of service enterprise cash flow in 2021, 2022, 2023

Month		January	February	March	April	May	June	July	August	September	October	November	December	
Income - Expenses		0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	14 932,32	2 237,75	-3 452,71	45 652,14	59 369,50

Source: author (2022)

The enterprise's income consists of:
- Incomes from the town – incomes for services provided to the town, which are controlled by the town budget. Incomes from the town are determined by the town budget, they are fixed income, changes to the budget must be approved by the town council.
- Income from other customers – income from services provided to customers other than the town. These incomes can be a maximum of 20%. Considering its capabilities, the management has set a objective of achieving income from other customers in the amount of 5% of the maximum amount for 2022.
- Subsidies for wages of disadvantaged and vulnerable workers, this amount is affected by the wage of a vulnerable or disadvantaged worker, if the worker is unable to work, his wage depends on the number of days worked, in the case of long-term sick leave it is zero wage, i.e. zero subsidy.
- Subsidies for the wages of workers assigned in non-refundable financial assistance project, this amount is also affected by the wage of the worker, but these workers are not disadvantaged or vulnerable.

- Loans – the loan for the telescopic lift.
- Owner's contributions – share capital, loans, owner's donation.
- Other monetary income - income from the sale of long-term assets, etc.

Enterprise expenses consist of:

- Wages - all costs associated with wages are included here - levies, taxes, food allowances, bonuses.
- Operating costs - costs associated with the operation of the business - gas, maintenance of equipment and vehicles, office supplies, various fees, etc.
- Repair and maintenance of town property costs – are costs associated with town maintenance, mostly with town buildings – revisions of technical equipment of buildings, repairs, building maintenance, etc., these costs are planned within the town budget.
- VAT – value added tax.
- Taxes - other taxes, e.g. road tax.
- Returns to the town - if the amount on the pre-invoice was greater than the amount for the services provided, it is necessary to return the difference in the form of a return.
- Investment costs.
- Loans.

All costs can be considered fixed. For the year 2022, investment costs were also planned for the purchase of a telescopic lift and a flatbed truck, which are mandatory conditions of the non-refundable financial assistance project.

From the analysis of the enterprise's cash flow in the current situation, it can be estimated that the enterprise will reach a negative cash balance in October (when it will be necessary to pay for the ordered flatbed truck), which will last until the end of the year. It indicates that the enterprise will not be able to repay its obligations on time. If no measures are taken, the enterprise will not be able to repay its obligations in the long term from May 2023 when the non-refundable financial assistance project will end and will be headed for **bankruptcy.**

The only way to avoid bankruptcy is to invest funds for the purchase of the flatbed truck and for a financial reserve so that changes can be made to improve the conditions for increasing the sale of services for other customers, i.e. to choose a strategy of income growth in any form. In the current situation, it is not possible to try to reduce costs, as all costs are considered to be fixed, in addition, enterprise must also think about current inflation and price increases. The only way would be to reduce wage costs, i.e. to dismiss several workers who are not fixed for subsidies, but this requires additional immediate costs associated with severance pay, with a reduction in the number of three workers, this would amount to approximately €6,000, which is a high cost considering the situation.

In the following part, the analysis of the scenarios from the optimistic, pessimistic and realistic point of view was processed. Subsequently, measures (strategies) were proposed for each scenario:

Optimistic scenario: In order for the enterprise to make a profit, it is necessary to increase the budget by minimum of 14% and income from the sale of services to other customers by minimum of 125% while maintaining the current costs. However, the development of prices on the market must be monitored and the costs for the next year analyzed accordingly. The analysis of the cash flow after the implementation of the measures shows that the enterprise will avoid bankruptcy in 2023 and achieve at least a minimal profit.

Proposed measures for an optimistic scenario:

- The owner will provide the amount that was returned together with the financial reserve for measures for changes that will improve the conditions for increasing the sale of services to other customers, a total of €57,000 - e.g. by increasing the share capital, providing a subsidy, donation, sale of land.

- The enterprise will take measures to increase the sale of services to other customers - e.g. purchase of new equipment, acquisition of qualified workers, improvement of marketing.
- For 2023, the enterprise will set a price list for town maintenance with higher prices and thus a higher budget.

Realistic scenario: The analysis of the cash flow after the implementation of the measures shows that the enterprise will avoid bankruptcy in 2023, but there is a risk that its economic result will be a loss, which would be the third loss in a row since the beginning of the enterprise's functioning. This would give a negative image of the enterprise in front municipal council and citizens of the town.

Suggested measures for a realistic scenario:

- The owner will provide the amount, which the flatbed truck will be paid with - as in the optimistic scenario, e.g. by increasing the share capital, providing a subsidy, donation, sale of land.
- The enterprise will take measures to optimize human resources after May 2023, when the non will non-refundable financial assistance project end - it will reduce wage costs by dismissing at least 3 employees whose contract ends in March 2023 in order to avoid paying severance pay. By doing so, however, enterprise will lose qualified administrative workers and truck operators, so it would have to take measures to cover these activities.
- The enterprise will take measures to increase income from the sale of services to other customers, but at minimal costs and without offering new services - e.g. constantly reaching out to potential customers.
- For the year 2023, the enterprise will set a price list for town maintenance with higher prices and thus a higher budget by minimum of 6%.
- The enterprise will look for additional subsidy projects for registered social enterprises.

Pessimistic scenario: The analysis of the cash flow after the introduction of the measures shows that the enterprise will avoid bankruptcy in 2023, but there is a risk that its economic result will be a significant loss, which would be the third loss in a row since the beginning of the enterprise's functioning, so the enterprise would have to consider taking measures to achieve profit in 2024.

Proposed measures for a pessimistic scenario:

- The owner will not provide any amount, the enterprise will have to take measures to pay for the flatbed truck - e.g. lease the flatbed truck, but this will require approval from the bank that provided the loan within the non-refundable financial assistance project, where one of the conditions was to invest own funds.
- The enterprise will optimize costs in 2023 – reduce wage costs by dismissing at least 3 employees whose contract ends in March 2023 in order to avoid paying severance pay. By doing so, however, enterprise will lose qualified administrative workers and truck operators, so it would have to take measures to cover these activities.
- The enterprise will set the same objective for income from the sale of services to other customers as in 2022, keeping its current customers and finding new ones at minimal costs.
- For the year 2023, the enterprise will set a price list for town maintenance with higher prices and thus a higher budget by minimum of 4%.

3.3 Taking measures with regard to the long-term development of the enterprise

The efficiency of providing the maintenance for town is not displayed in a reduced budget for the town maintenance, but in the improvement of services and the providing greater number of different services for the town. The financial performance of the enterprise depends on which scenario and which long-term strategy enterprise will choose.

In the current situation, it is possible to propose the following enterprise strategies for long-term development:

- An enterprise that will function as before and the main focus will be the maintenance of the town.
- An enterprise whose main focus will be the maintenance of the town, but with the new equipment so it will be able to offer these services to other customers at a profit.
- An enterprise that will implement a new type of services that will be profitable.

3.4 Implementation of measures with regard to the long-term development of the enterprise

The most difficult step will be obtaining the consent of the owner for the chosen scenario, because if the enterprise does not want to get into an unmanageable crisis, the consequence of which will be bankruptcy, it must invest additional funds, which come from public sources, and therefore the consent of the town council will also be necessary.

The management of the enterprise must plan individual measures and manage the risks associated with them. It is also important for the enterprise to monitor these measures together with own activities. The best way to monitor its activities and measures is to establish key performance indicators (KPI):

- KPIs for measures that can be used are:
- compliance with the deadlines of the individual tasks of the measures,
- effectiveness of individual measures, i.e. whether the measures fulfill their objectives,
- the degree of risks associated with the implementation of measures, or the identification of new risks,

KPIs for enterprise activities can be:

- monitoring cash flow and achieving its objectives,
- income from the sale of services for other customers,
- rate of fulfillment of weekly action plans,
- degree of equipment usability,
- efficiency of operating costs.

The enterprise is in an environment that is affected by a number of influences, where the situation cannot be predicted exactly, therefore it is necessary to regularly monitor the course of individual measures, a suitable tool is action plan. The status and course of measures to manage the crisis should be communicated with the owner (including the town council), the advisory committee for registered social enterprises and employee representatives, in order to know the current situation of the measures and, if necessary, propose new ones.

4 Conclusion

The service enterprise got into a financial crisis very quickly due to wrong management decisions and related cash flow problems. The main reasons were that the enterprise was not sufficiently financed when it started, the share capital was non-monetary, the costs of starting the enterprise were not taken into account, and the main reason was the setting of financing in the form of a subsidy from the town, which resulted in the return of the subsidy from the

Office of Social Affairs and Family back to town. As part of the processed study, scenarios and measures were proposed that would help prevent bankruptcy. The most advantageous solution is for managers to accept the measures of optimistic or realistic scenario that will bring a significant improvement in cash flow and profit in the future. In the case of a pessimistic scenario, the enterprise will turn away from bankruptcy, but will not fulfill its original strategy and will be in a significant economic loss. It is also possible to prepare a scenario by combining the mentioned measures. However, if the enterprise does not adopt any of the mentioned measures and continues to perform its activities with the current status, it is certain that it will be at risk of bankruptcy in 2023.

The results of a case study in a specific service enterprise point to the need to pay attention to the prevention in the form of risk management. Through risk management, the enterprise's management can identify the key risks that threaten the fulfillment of the main objectives and propose measures to reduce them. The attitude and approach of responsible managers to risks and overall prevention in the enterprise is also important. As the study shows, a suitable method is the analysis of scenarios, with the help of which the enterprise can think about its future development, the possible financial consequences and can take appropriate measures to prevent a enterprise crisis, or bankruptcy. The effective application of risk management can help to be better prepared for other strategic threats and negative events affecting the operation and management of enterprises. The authors of the paper believe that they will find understanding among responsible managers not only in Slovakia but also in other countries of the world, to deal with risk management in order to increase the prevention of enterprise crises. The processed results of the study are of benefit mainly to business managers, risk managers, academics, etc. not only in the business sector, but also in the public sector in Slovakia and the world.

Enneagram as a motivation tool in a company in the process of globalization

Eva Kicová[1,*], and *Oľga* Poniščiaková[1]

[1]University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: In the process of globalization, one of the key prerequisites for the success of businesses is human resources. If the company wants to develop, assert itself on the market and gain a competitive advantage, it is necessary to create and constantly improve the conditions for acquiring high-quality labor and keeping them in the company. Human resources are considered the most valuable resource that a company has. It goes without saying that relationships in the workplace influence the motivation of employees to perform a given job. Currently, there are many "classic" motivational tools. Our goal is to point out non-standard tools for employee motivation and, based on their application in the selected company, point out their usefulness in business practice.

Purpose of the article: The purpose of the article is to point out the usefulness of the Enneagram in the field of employee motivation, to point out its advantages on a theoretical level; and, based on its application in a specific company, to point out its usefulness in practice.

Methods: The paper used methods of analysis and synthesis of theoretical knowledge. A survey was used to investigate interest in non-standard tools in businesses in the region of Trenčín. A structured interview was also used to obtain the opinion of the business owner, and a questionnaire survey with an evaluation of the answers was conducted.

Findings & Value added: The Enneagram was used in a company as a motivational tool in a specific company. On the basis of structured interviews with the company manager and questionnaire surveys with employees, we can conclude that the Enneagram has its application in corporate practice in the Slovak Republic and, from our point of view, is an effective tool for motivating employees in the company.

Keywords: *Enneagram, human resources, motivation*

1 Introduction

In the process of globalization, it is necessary to pay increased attention to several areas of the economy and management. From our point of view, the issue of human resources is also important. It is often the basis for the success of businesses. From our point of view, motivation for extraordinary work is important, and we consider it important that companies pay attention to it and look for different ways to motivate their employees. That is why I focused on the use of a non-standard motivation tool—the Enneagram. Our goal is to briefly approach this issue and find out how to influence the motivation of the Enneagram application in a specific company.

2 The theoretic background of the problematical

Here are many definitions of the term "motivation" in the professional literature. Despite the large number of definitions from different authors who understand motivation differently, it can be clearly pointed out that mutual similarities are evident. In the current science of the development of human potential and in other behavioral sciences, motivation is one of the most complicated phenomena. Motivation is hidden in every area of the economy and social life of every society and country. Steriopoulos explains the term "motivation" as the sum of all driving intrapsychic motives or forces. They usually stimulate and organize experience and behavior (Steriopoulos, 2020). The aim of this is to change the unsatisfactory situation that currently exists or to achieve something positive. Motivation is related to the processes that maintain and stimulate activities that are aimed at achieving a goal. Motivational processes are internal personal influences that lead to results. (Ryan et al., 2018) Khan describes motivation as a process of maintaining, directing, and energizing behavior. Despite the fact that this process is based on biological sources, it is considered a psychological phenomenon. It is a type of regulation that is guided by the psyche (Abbasi, 2017). According to Bal et al. (2020) motivation combines the physical and mental activity of a person, which leads to a set concrete goal. Through desires, ideas, interests, and, above all, unsatisfied needs, psychological tension can be induced, which can become an incentive for certain human behaviors (Bal et al., 2020). The term "motivation" can be understood as driving energies of a psychological nature because they set human behavior and activity in motion. forces because they have direction and intensity. (Sajjad et al., 2019) Motivation is a driving force that is responsible for initiating, maintaining, and guiding targeted behavior. The effect of external and internal stimulation (and its cognitive interpretation) creates a motivational force. Stimulations can be psychological (e.g. desire to succeed) or physiological (e.g. hunger). (Fiľa et al., 2009)

According to Wu et al. employee performance and motivation are directly linked to the management style and principles of negative or positive reinforcement that are applied in the company (Wu et al., 2021). The lot of authors talks about motivating employees as a systematic process. As part of that, senior staff continuously stimulate and encourage the enthusiasm and internal motivation of subordinate colleagues. They do this by uncovering and applying tools, measures, and approaches that help satisfy the intrinsic goals, needs, and aspirations of these workers. And thus, they encourage their more efficient work performance and appropriate behavior. Barth et al. based on research that aimed to determine the effect of training on the performance of subordinates, states that this research concluded that there is a positive relationship between the performance of a worker and his motivation and training (Barth et al., 2014). "In connection with motivation, the concept of motive appears as a factor influencing human behavior in a certain direction, which is difficult to define precisely because: motive cannot be directly observed; it is usually the action of several motives at the same time; the manifestation of the motive's effect on behavior can be different for each

person; motives and their actions are subject to change." (Hitka et al., 2021) Motives determine the direction and targeting of an activity, and thus also the course of a certain behavior and the content of a given activity. They also determine the intensity of the activity and what effort the individual will make to achieve his goal. The motive determines the duration of the given activity, which is usually finished by satisfying the need that triggered the activity. (Huffman et al., 2022)

In general, we know several types of motivation. External motivation is the motivation that an individual obtains from an externally influenced need; that is, he is motivated by external desires and needs. (Popadinets et al., 2021) Buckley stated in his article: "Intrinsic motivation is a type of motivation in which an individual is motivated by internal desires." In the mentioned article, Buckley also talked about the following types: Motivation based on rewards, which is a type of motivation in which an individual is motivated by receiving a reward if a certain goal is achieved, is Fear can also be a very powerful motivator if the fear of failure is strong enough. We call this kind of motivation "fear-based motivation. He also spoke about the motivation based on the achieved results, which appears in people for whom the achievement of a title or a certain position in employment or in other areas of human life is very important. We also know material and non-material motivation. In the case of material motivation, employees are provided with tangible rewards, which include, for example, a salary increase. Intangible motivation, and therefore intangible factors, further strengthens the will of employees to provide the best possible work. Intangible factors include, for example, the opportunity for personal development. (Di et al., 2022) Some authors defined individual motivation and work group motivation. According to her, when motivating an individual, emphasis is placed on the manager, whose abilities and skills are very important in motivation. For the application of this type of motivation, it is essential that the manager thoroughly knows, understands, and addresses the value ranking of the employee ((Chen et al., 2020).

Nowadays, we know a lot of theories that deal with the motivation of individuals and entire groups. The causes of the emergence and development of these theories can be found on the side of workers (development of their skills, initiative, attitudes of employees at work), but also on the side of management (management style, etc.) (Brown et al., 2020). For the purposes of this paper, we divided motivational theories into "standard" and "non-standard" categories. The literature currently offers a large number of "standard" motivational theories. According to Bal et al. (2020), a large number of theories have been developed over the past decades that are based on basic human needs. These are, for example, Maslow's theory, Alderfer's motivational theory-ERG theory, Herzberg's two-factor theory, Adams', Vroom's, and many others.

Among the "non-standard" we will consider the Enneagram. The word Enneagram itself has its origin in Greek, consisting of the words "ennea", which means nine, and "grammos", which means shape or scheme. The Enneagram can be defined as a geometric representation of the nine primary personality types; it also depicts the complex interconnectedness of these types. It is important to realize that none of these nine types is worse or better than the others. Each type has its strengths and quirks. (Bayne et al., 2021) The exact history of the Enneagram is not known, but what we do know is that in the form we know it today, it was created by combining various religious and spiritual traditions. These traditions have been created by Christians, Muslims, Buddhists, and Jews over the millennia. (Di et al., 2022)

As stated by Bland (2010), the Enneagram symbol was brought to the modern world by Georgi Ivanovich Gurdjieff. He was interested in esoteric thinking from an early age. On his travels around the world, which he carried out in order to explore different thought systems and teachings, he encountered the Enneagram symbol in Afghanistan or Turkey. Then he created his own synthesis from his knowledge, which he later taught in St. Petersburg and Moscow. "With its focus on the development and identification of hidden potential, the

Enneagram typology can be a powerful tool for employee development and talent management." (Bal et al., 2020) The Enneagram is currently being applied in various fields and professions. It is used, for example, in the fields of education, business and sales, in psychotherapy, medicine, and others. Various companies, such as the Walt Disney Company and Silicon Graphics, use the Enneagram as a tool for conflict resolution, communication skills development, leadership development, coaching, strategic planning, and team effectiveness. (Di et al., 2022) Steriopoulos (2020), who uses Enneagram and currently works in venture capital, states in her article, "Like any personality assessment, it is not a science. However, it is a useful tool for understanding your own and other people's tendencies so that we can anticipate conflicts and harmonious relationships. " As she states, she encountered the Enneagram several years ago when she was working on a startup with her friend and co-worker, who introduced her to the Enneagram. She introduced the Enneagram. Since then, he has been using it in his work to find out how people can react to different events and to understand why people behave in certain ways (Ryan et al., 2020).

The Enneagram symbol itself consists of three parts that represent the three laws of God. They are as follows: 1. circle ("God is only one")-means harmony, unity, wholeness, 2. triangle-("Holy Trinity"-Father, Son, and Holy Spirit/Christianity/; "Three spheres"-Keter, Bina, and Chochma/Judaism/) -According to most world religions, the universe is not the result of duality but of trinity 3rd hexagon-("The Law of Seven"-describes development and process over time)-nothing is static and unchanging, everything is in motion and it transforms into something new. (Brown, 2020)

The Enneagram includes nine different personality types. However, the system is a bit more complicated. In addition to these nine types, it also includes three key centers. (Wu et al., 2021). According to Bland (2010), these are the following centers: • belly center - this personality type includes personality types 8, 9, and 1. These mentioned types react instinctively; they are mostly open and direct. Alternatively, they hide aggression. If they are not successful, they consider it their fault. • center of the head-this includes personality types 5, 6, and 7. As the name suggests, personality types of the center of the head think about everything a lot. They do not act without thinking everything through first. 20 • center of the heart-this includes personality types 2, 3, and 4. These types are very focused on interpersonal relationships. They want to be accepted. They let themselves be influenced by what others think of them, and many times they think they know what is best for others. These types often suppress their aggression. These centers shape the way individuals function in the world. Each person can control one of three instinctive subtypes. These subtypes are: self-preservation, individual (sexual), and social. (Bland, 2010) "Each type is characterized by a number of traits that dominate the individual's overall personality. The model also identifies the greatest anxieties of each type, as well as the coping mechanisms people use to deal with those anxieties. " (Ryan et al., 2020).

Figure 1. Enneagram

Source: Downey, 2017

Type 1-The Reformer (also called a perfectionistic, teacher, white knight, activist, reformer, moralist, or organizer) is a rational type, balanced, principled, and determined. As Cherry states in his article, "The imperfection of the self arouses anger in the unit, and this brings about a paradoxical situation. This anger is the root of the sin of unity. It is hard to recognize (compared to visible sins like immorality, etc.) because the unit is ashamed of its anger! She doesn't want to admit that she is driven by anger, and she doesn't even want to admit to herself that she is aggressive-after all, anger is a manifestation of imperfection (Bayne et al., 2021).

Type 2-The Helper (also known as lover, altruist, pleaser, nurturer, exceptional friend) is an open, generous, and possessive communicative and caring personality type. (Ball, 2009) According to Bland (2010), twos should realize that it is not selfish to be angry sometimes and should admit when someone hurts them. They need to understand that it's perfectly okay for them to need help sometimes. Above all, they should realize that they have the right to say "no" (Bland, 2010).

Type 3-The Achiever (also called an winner, actor, motivator, entrepreneur, role model, or social climber) is a pragmatic type whose goal is to succeed. This type is an excellent, adaptable, and motivated person. He bases himself on his image. (Abbasi, 2017) The winner charms people by using an image that impresses them so he can manipulate them. (Cherry, 2019) The troika strives to gain a good status in society. This type is very competitive and wants to succeed in any field in which he works.

Type 4-The Individualists (also known as romantics, artists, melancholics, tragic victims, esthetes, or the "strange") are highly sensitive and closed-minded personalities. It is characterized by high temperament, theatricality, and egocentrism. (Khan, 2012) Characteristics of this type include valuing creativity, aesthetics, dignity, humor, and compassion. He values authenticity and loves beauty. On the other hand, this type often experiences a feeling of depression, behaves too dramatically, and wants to be moralistic. (Bal et al., 2020).

Type 5-The Investigator (also called thinker, computer scientist, innovator, specialist, radical, exporter) is an intellectual type. He stands out for his intelligence, ingenuity, and sensitivity, and those around him often perceive him as mysterious and lonely. (Cherry, 2019) This type lives from a distance, avoids emotional involvement, and prefers to observe rather than engage. The observer is usually a closed person. He can feel exhausted and nervous if he does not have enough time for himself. (Fiľa et al., 2020)

Type 6-Loyalist (another name is, for example, traditionalist, soldier, devoted follower, devil's advocate, convinced supporter, problem solver) is a devoted type who relies on certainty. He is charming, anxious, responsible and suspicious. The Six identifies the sources of potential threats and imagines the worst possible scenarios. This can lead to procrastination and suspicion of other people's motives. They often question authority. Bayne also stated in her article that the six are a skeptical and cautious type. The goal of this type is to be ready for anything that might come their way in life (Bayne et al., 2021).

Type 7-Enthusiast (also called hedonist, optimist, entertainer, multitasker, storyteller, dilettante, energy rebel) is a cheerful, busy type. He is versatile, spontaneous, often unfocused and not temperate. He desires to live a pleasant and happy life. This leads to an escape from reality to exclude negative emotions and possible wounds that would prevent him from presenting himself as an effective and optimistic person. (Hitka et al., 2022).

Type 8-Challenger (also known as leader, protector, breadwinner, or entrepreneur) is a confident, aggressive, and stubborn type. Tanner stated, "As eights mature and learn to acknowledge their softer and more vulnerable sides, their relationships deepen and improve drastically" (Bland, 2010)).

Type 9-Peacemaker (or peacemaker, healer, comforter, optimist, utopian) is a modest, calm person. He is perceptive, he mostly agrees with the opinions of others, he is indifferent and reassuring (Downey, 2017). It is important for this type to discover and develop a sense of their own importance, life force, and human worth. He must discover his own inner impulse so that he can be independent of stimuli from the outside world. With the Enneagram, we also talk about the so-called wings of the Enneagram. They are shown in Figure 1. Wings help us individualize the nine (more general) types of the Enneagram. Wings are the two types that are on either side of our type (Bayne et al., 2021).

2 Methods

On the basis of a survey conducted among companies in the region of Trenčín, we tried to find out what HR professionals think is the level of motivation in companies and what tools are used within companies. We also tried to find out the interest in using non-standard tools as part of motivation. A total of 20 businesses in the Trenčín Region were approached. On the basis of the results, it can be concluded that the principles of "standard" motivation tools are primarily used in companies, while one company showed interest in the application of non-standard tools as well. It is a small business that employs 11 employees from the construction industry. First of all, we conducted a structured interview with the business owner in the company, while using the Riso-Hudson QUEST and the Riso-Hudson TOP tests, we determined what Enneagram type the business owner himself is. Subsequently, tests were carried out to determine individual personality types for all employees. Once we knew what Enneagram types were in the company, we provided the owner with descriptions of the individual types. In them, we summarized the basic character traits of the types, their strengths. In the descriptions, we have also indicated the ways in which it is appropriate to communicate with employees because the individual types are significantly different and different methods apply to them. We also worked with their emotional intelligence, so that they could understand themselves and other people. The goal was primarily to improve relations and communication within the company. The employer applied the principles of communication with employees for a period of 6 months. After that, we again conducted a structured interview with the owner of the business, and we also conducted a questionnaire with the employees to find out what changes in the fields of communication and motivation have occurred in the company.

3 Results and Discussions

When comparing the answers to the questions in both questionnaires, we noticed the following changes:

- *How do you perceive motivation from the employer?*

In the first questionnaire, most employees, specifically six, perceived the motivation from the employer as average. One of them felt that the employer was not interested in motivating his employees. Four employees rated the employer's positive motivation. In the second questionnaire, the number of employees who perceive motivation from their employer on average remained unchanged, i.e., six. The change occurred in the case of a negative perception of the motivation from the employer, where at the end of the period, not one of the workers perceived the motivation negatively. On the contrary, there was an increase of one employee in the case of a positive perception of motivation from the employer.

Conclusion: In terms of the perception of motivation from the employer, there were no significant changes in the company. But we have seen a small improvement.

- *Rate workplace relationships on a scale of 1 to 5.*

In Table 1, you can see how employees evaluated their relationships with colleagues in the first questionnaire. Table 2 shows the answers of the employees in the second questionnaire.

Table 1. Relationship with co-workers—first questionnaire

Relationship with co-workers	
1 – very bad	0 %
2 – bad	27 %
3 – good	45 %
4 – very good	18 %
5 – excellent	9 %

Source: own source

Table 2. Relationship with co-workers—second questionnaire

Relationship with co-workers	
1 – very bad	0 %
2 – bad	18 %
3 – good	38 %
4 – very good	39 %
5 – excellent	9 %

Source: own source

Conclusion: Regarding the issue of relations with the employer, even more significant changes can be seen after the application of the Enneagram than in the case of relations with co-workers. Initially, up to 27% of workers perceived this relationship badly. In the second questionnaire, this number dropped to 9%. That is two workers less than at the beginning. The same number of employees as at the beginning perceive their relationship as good. One more employee perceives their relationship as very good—from the original 18% to 27%. Even one of the employees rated his relationship with the employer as completely problem-free. Despite the fact that the relations with the employer are still not the best in all cases, after applying the Ennegram, we see an improvement in some cases.

- ***Are there conflicts with co-workers in your job?***

The answer to this question was identical in the first and second questionnaires. Ten workers, representing 91%, confirmed that there were conflicts between them and their co-workers. One employee, which is 9% of the total number of employees, does not enter into conflicts.

Conclusion: Conflicts between employees still occur in the company.

- ***If you answered yes to the previous question, how often?***

In response to the first questionnaire, seven employees stated that conflicts occur frequently (several times a week). According to two, conflicts occur occasionally (a few times a month). According to only one, conflicts occur rarely (about once a month). According to the second questionnaire, conflicts occur often (several times a week), according to four employees. The same number of employees gets into conflicts occasionally (a few times a month). Rarely (about once a month) do two employees come into conflict.

Conclusion: Although conflicts between employees still occur in the company, differences can be seen between how often they occurred before and now after 50 applications of the Enneagram. Previously, seven employees were conflicted several times a week; now there are four, which is a significant difference. From the original 9% of employees who rarely came into conflict with others, this number increased to 18%, which is a favorable phenomenon.

- ***Are there conflicts with your employer in your employment?***

According to the first questionnaire, all employees of the company came into conflict with the employer. According to the second questionnaire, ten employees have disagreements with their employer. One stated that such situations with a superior do not occur at all.

Conclusion: Despite the fact that there are still conflicts between the employer and employees, we have noticed a change in one worker, who has not come into conflict with the employer lately.

- ***If you answered yes to the previous question, how often?***

According to three employees, before the application of the Enneagram in the company, there were frequent conflicts between them and the employer (several times a week). In this first questionnaire, seven workers stated that arguments occur occasionally (a few times a month). Rarely did one employee come into conflict with a superior. According to two employees, disagreements often occur after applying the Enneagram. Five, conflict situations with the employer occasionally arise. The three employees rarely come into confrontation with their supervisor (approximately once a month).

Conclusion: Conflicts with the employer still occur in the company, but improvement can be seen. From the original 27% of workers, now a little less, specifically 18%, come into conflict several times a week. Also, the option "occasionally", which means a couple of times a month, is marked by two fewer employees—from the original 64% to 45%. More than two employees rarely come into conflict—from 9% to 27%. This is ultimately positive.

- ***Are you satisfied with the atmosphere at the workplace in the company?***

In the first questionnaire, only one employee stated that he was satisfied with the atmosphere at the workplace. The three were rather satisfied. Four were rather dissatisfied, and three were not satisfied at all. After applying the Enneagram, the results of the second questionnaire on this issue were as follows: Two employees were satisfied. Rather, the number of satisfied people remained unchanged, three. One of the employees could not comment. Rather, the number of dissatisfied people remained unchanged at four. One employee was not satisfied with the atmosphere at the workplace.

Conclusion: Certain changes occurred in workers' satisfaction with the workplace atmosphere after applying the Enneagram. From the original 36% of the company's employees who were satisfied and marked "yes" and "rather yes", their number increased to 45%. The number of employees who are rather dissatisfied remained the same. A positive change occurred in that from the original 27% of dissatisfied workers, this number dropped to 9%.

- ***How do you perceive communication with your superior?***

According to the first questionnaire, most of the workers in the company understood everything that their superior was saying, and they felt that he was also willing to listen to them. One employee perceived the communication as understanding, but the supervisor was not listening. The three employees did not understand everything their superior was saying. Of which, according to two, he tried to explain things to them, and according to one, he did not. According to the second questionnaire, three employees said that they understand everything, but the employer does not listen to them. Three said that they do not understand everything, but the superior tries to explain it to them.

Conclusion: In both cases, the situation was favorable when 64% of the company's employees evaluated the communication positively, saying that they understood everything. From the original 18%, the possibility that the employees do not understand everything, but the employer is willing to explain things to them, has increased to 27%. It is also positive that not a single employee identified with the option "you don't understand everything your superior tells you and he doesn't even try to explain it to you". It follows from this that there have been certain, albeit small, changes for the better in the area of communication between the employer and employees.

Following the implementation of the Enneagram, certain changes occurred in the company. This tool was used in the company for approximately three and a half months. All employees of the company stated that, according to them, the atmosphere at the workplace is their motivation to work. Although conflicts between employers and employees still occur in the workplace, those between employees and employers occur less frequently. Following on from that, the employees also expressed somewhat greater satisfaction with the atmosphere in the workplace, which supports their motivation to work. There were also other changes in the field of communication in the company. Small positive changes can be observed after applying the Enneagram. In cases with a longer time horizon, the results could be even more visible. Well, even for this short period, it can be evaluated that after applying the Enneagram as a motivation tool, relations in the company improved, and thus also the motivation in the company improved.

As already mentioned, we supplemented the survey with a structured interview with the business owner. Based on this, the following can be stated.

Conclusion of the first interview: According to the employer, employee motivation is important and uses various motivational tools to improve the level of motivation in the company. He considers the atmosphere at the workplace to be an important factor. In the company, there are conflicts between the employer and the employees, while the employer sees the main reason for these conflicts in different personalities and opinions. The employer rated his relationship with the employees on a scale from 1 to 5, with 1 being the worst and 5 being the best. 3. The employer tries to create an atmosphere of openness, friendliness, and trust in relation to the employees. He tries to stimulate the opinions and suggestions of his employees.

Conclusion of the second interview: The employer noticed changes in both his employees and himself after applying the Enneagram as a motivational tool. Over time, he noticed more open communication with some employees. He also noted a better atmosphere and fewer conflicts in the group in which he works. He noticed changes in himself in the form of fewer

conflicts in his personal and professional life. The employer began to show more interest in the needs and opinions of the employees. The employer continued to try to support the motivation of employees. In addition to the motivational tools that he had already mentioned during the previous interview, he began to attach more importance to providing employees with sufficient information. He also tried to be more interested in the opinions of employees and gave them more space to solve problems. According to the employer, even after applying the Enneagram, conflicts still occur in the company, but to a lesser extent than before. He rated his relationships with employees on a scale from 1 to 5, with 1 being understood as the worst and 5 as the best, at 3.5–4. The employer rated the effect of the Enneagram on the company positively.

4 Conclusion

In the process of globalization, it is necessary to pay attention to the motivation of employees and through it to influence the overall efficiency of the company. Surveys in the form of a poll have shown that companies mainly use "classic tools" of motivation, and their interest in non-standard tools is low. However, from our point of view, this could have been caused by the still dying pandemic.

On the basis of structured interviews with the employer before and after the application of the Enneagram, it can be concluded that, in his opinion, this tool influenced the atmosphere at the workplace, communication, and thus motivation in the company and also in the personal life of the business owner. Over time, he noticed more open communication in the case of some employees, an improvement in the atmosphere at the workplace, and also fewer conflicts in the work group, of which he is also a part. Despite the fact that even after the application of the Enneagram, conflicts have not completely disappeared from the company, it records them to a lesser extent than before. The business owner evaluated the Enneagram positively as a motivation tool in his company. As for the employees, they perceive that motivation is important for better performance. Most of them are of the opinion that the atmosphere that prevails at the workplace affects their motivation to work. After evaluating both questionnaire surveys and the changes between them, it can be concluded that certain positive changes occurred in the company after the application of the Enneagram. At the beginning of the period, the overwhelming majority were dissatisfied with the mood that prevailed in the workplace. This improved somewhat after applying the Enneagram. We are also aware that the results were evaluated after 6 months of Enneagram application, and from this point of view we evaluate them positively. In the end, overall communication, relationships and motivation improved, which was our goal.

Renewable Energy Sources and Its Impact on Employment in the Globalized Environment

Mária Kmety Barteková[1,*], and *Daniela* Rybárová[1]

[1] University of Economics in Bratislava, Faculty of Business Management, Dolnozemska cesta 1, 852 35 Bratislava, Slovakia

Abstract

Research background: The energy transition offers significant employment opportunities across different countries and market segments. The trends in the educational requirements of the energy sector call for better co-ordination between the sector and educational institutions. An integrated approach to labour and educational policy and planning will be needed to address this challenge, and also to better integrate the educational requirements in the energy sector with those of other sectors.
Purpose of the article: The aim of the paper is to measure the impact of Renewable energy sources on development of employment in the globalized environment.
Methods: Our calculations are based on data from Eurostat and the Statistical Offices of the selected countries for last ten years. To answer the research questions, we chose regression analysis.
Findings & Value added: The estimates are done for employment in solar PV, liquid biofuels, wind and hydropower. Less information is available for other technologies such as solid biomass and biogas, solar heating and cooling, concentrated solar power (CSP), geothermal energy and ground-based heat pumps, waste-to-energy, and ocean or wave energy. At 4 million workers worldwide, the solar PV industry employs a third of the total renewable energy workforce. Decent jobs will not be created automatically in the energy transition; ambitious policy support and investments in a future-oriented, climate-safe and just energy transition will need to be sustained and expanded.

JEL Classification: *E24, E29, O13*

1 Introduction

The use of renewable energy provides many benefits on the global, regional and local scale. The improvement of the environment condition and the improvement of energy safety (Gradziuk and Gradziuk, 2018, Simas and Pacca, 2014) are the most frequently highlighted ones. Distributed power prevents major disturbances in the event of power grid or power

----

* Corresponding author: maria.bartekova@euba.sk

providers' failure. Moreover, such strategy minimises costs of constructing and using transmission lines, as well as enhances provision of power, especially to areas with poor power infrastructure. The development of the use of renewable energy sources results in increased employment (Baranes, Jacqmin and Poudou, 2017, Moreno and Lopez, 2008; Afşar and Özarslan Doğan, 2021).

Germany has long known how to take advantage of the benefits of globalisation. Today, exports of goods and services account for around half of the country's value added. One in four jobs depends on exports; in industry, this is true for even more than every other job. Exports are not the only decisive factor here. As a manufacturing nation, Germany also heavily depends on inexpensive, high-quality imports.

Globalisation is a double-edged sword, especially for emerging market economies. Like other emerging market economies, China has responded with sound macroeconomic policy and structural reforms to create a good domestic environment for participating in globalisation. China is adapting to the new normal of economic development and deepening supply side structural reforms. The government have sought to encourage technological innovation, increase investment in education, and improve labour quality and total factor productivity (Praene et al., 2021, Selvanayagam, 2006). China aims to cut costs for enterprises, reduce real estate inventory through tax measures, land and resource price reforms, and to reform the administrative system by streamlining administration and delegating powers (Mu et al., 2018).

For decades Germany has been the global pioneer in applying renewable energy and environmental technologies (Lehr et al., 2008). In 2019, 46% of the country's electricity mix came from wind, solar, biomass and hydroelectric sources. That's up 5.6 percentage points over 2018. The bulk of the clean power came from onshore and offshore wind capacity (24.4%), followed by solar (9%) and biomass (8.7%), with the remainder stemming from hydropower. All in all, 238.37 terawatt hours of electricity were generated by all renewable technologies.

According to IRENA (2022) in Germany, wind energy sector creates the largest amount of jobs in RES employment (Figure 1).
Figure 1. Structure of RES employment in Germany (2021)

Source: IRENA (2022)

In China, solar photovoltaic sector represents almost half of all RES jobs (Figure 2).

Nevertheless, the international community should be assured that China is genuinely interested in leading the world in one particular sector: deployment and investment in renewable energy (Kumar, 2020). China is already leading in renewable energy production figures. It is currently the world's largest producer of wind and solar energy, and the largest domestic and outbound investor in renewable energy. Four of the world's five biggest renewable energy deals were made by Chinese companies in 2016. As of early 2017, China owns five of the world's six largest solar-module manufacturing companies and the world's largest wind turbine manufacturer.

2 Methodology and Methods

In this chapter, we described the purpose of the research paper and methodology used to fulfil the stated aim.

2.1 Research aim

The aim of the paper is to measure the impact of Renewable energy sources on development of employment in the globalized environment, especially in Germany and China. In the paper, we articulated the following research questions:

- Research question no. 1: What is the impact of the renewable energy sources on overall employment in globalized environment of China and Germany?
- Research question no. 2: What is the impact of the renewable energy sources on the economic development of China and Germany?

2.2 Methodology of the research

The KOF Index of Globalization aims to measure the rate of globalization in countries around the world. Data used to construct the 2020 edition of the index was from 2019. The index is based on three dimensions, or core sets of indicators: economic, social, and political. Via these three dimensions, the overall index of globalization tries to assess current economic flows, economical restrictions, data on information flows, data on personal contact, and data

on cultural proximity within surveyed countries. Globalization is defined for this index as the process of creating networks of connections among actors at multi-continental distances, mediated through a variety of flows including people, information and ideas, capital and goods. It is a process that erodes national boundaries, integrates national economies, cultures, technologies and governance and produces complex relations of mutual interdependence.

Figure 3 and Figure 4 declared the level of globalization in China and Germany.

3 Results and Discussion

Germany has historically been a global leader in renewable-energy research, thanks to its sustainable-energy agenda and high levels of public funding. The result has been a wealth of opportunities for scientists working in the private and public sector. The renewable-energy field employs nearly 340,000 people in Germany, and according to the Federal Ministry for Education and Research, there are now more than 180 universities and 120 research institutes involved in the country's energy-transition programme "*Energiewende*".

Figure below shows the increasing trend of renewable energy patents till 2020 in Germany.
Figure 5. Renewable energy patents evolution in Germany

Source: IRENA (2022)

Figure 6 shows year-to-year increasing development of the renewable energy patents in China from 2009 till 2021.
Figure 6. Renewable energy patents evolution in China

Source: IRENA (2022)

The second phase of the China Renewable Energy Scale-up Program, scheduled to run from 2014 to 2021, is of great importance to supporting policymaking, innovation and industrial layout optimization. The program, jointly developed by the National Energy Administration, the World Bank and the Global Environment Fund, was set to support the 13th Five-Year Renewable Energy Development Plan (2016-20) in China and promote the large-scale sustainable development of renewable energy by reducing costs and improving efficiency.

Table 1 shows the results of regression analysis in Germany. Only the strong positive relationship between the RES employment and GDP development was confirmed.

4 Conclusions

Owing to the instability and intermittency of power generation from new energy sources, the rapid growth of new energy not only has significant impacts on the generation side but also poses great challenges to the stability and security of the power grid. Therefore, additional equipment is required to maintain the balance of the power grid (Bali Swain, Karimu and Gråd, 2022, Bulavskaya and Reynès, 2018, Chen, 2019), such as peak-shaving power plants

and related equipment, which can also bring new job opportunities in the power sector and related industries.

Pumped-storage hydroelectricity is considered to be an excellent option for peak-shaving (Lindner, Legault and Guan, 2013, Chen, 2019, Zhao and Luo, 2017), and provided more than 40 000 jobs with a capacity of 40 GW in 2020, while the workers will increase to more than 100 000 in 2050. Moreover, electrochemical energy storage is another important solution to peak-shaving in China, and not only works in conjunction with power plants on the generating side but can also be arranged separately on the user side. In 2018, the total installed capacity of electrochemical energy storage reached 1.02 GW, and more than two-thirds of the market share is taken by lithium-ion batteries. The largescale application of energy storage batteries in the future will bring plenty of new job opportunities in battery production, lithium mining and the chemical industry.

The Chinese government places a priority on investing in renewable energy primarily because it enables the country to tackle problems of air and water pollution and mitigate risks of socio-economic instability.

As one can see, the p- values in case of China are lower than 0.05. In first case R coefficient is 0.996, which is close to one. This means that there is a very strong relationship between our variables (RES employment and Total employment). To answer the second research question, we have identified that there is a very strong positive relationship between RES employment and GDP (p value 0.002 and R coefficient is 1.0). The strong positive relationship between RES employment and GDP development was confirmed in Germany.

Analysis of the innovation potential of business entities within the Slovak Republic and assessment of their performance from the international business point of view

Boris Kollar[1,*], and *Lubica* Gajanova[1]

[1] University of Zilina, Faculty of Operation and Economics of Transport and Communications, Univerzitna 1, 010 26 Zilina, Slovakia

Abstract

Research background: The motivation behind the creation of presented article is evaluation of innovation potential of subjects under the conditions of Slovak republic and its business environment. This potential for innovations lies in the in the assessment of companies' degree of innovativeness because this is currently considered to be one of the main conditions for the competitiveness of companies. The article categorizes and integrates innovations into basic logical units. Innovative elements in these units have common innovative elements, the possibility of their legal protection because of their intellectual property status. At the same time, the article focuses on the analysis of the latest trends in the field of innovation that can be observed within the framework of Slovak companies.
Purpose of the article: To describe and analyse specifics of innovation potential under the specific conditions of Slovak economy and to assess its potential in comparison with other economics.
Methods: The paper is built mainly on the methods of formal logic like comparison, analysis, and synthesis along with deduction.
Findings & Value added: Comprehensive overview of the current state of innovation potential of companies in the Slovak republic and its state in the comparison with other countries in European Union and the world.

Keywords: *Innovation, patent, intellectual property, potential, competitiveness.*

JEL Classification: *G10; G20; O30*

1 Introduction

The motivation behind this paper is fact, that investments in research and innovation are investments in the future. These kinds of investments lead to new, innovative, more efficient

---

* Corresponding author: boris.kollar@fpedas.uniza.sk

products and services (Oliinyk et. al.,2018). Thanks to them, there can be increase in competitiveness and employment (Valaskova et. al., 2018). Innovations have also direct and indirect impact on areas, which are focal for future social development such as renewable energy, climate change, sustainable development, and modern waste management. Because of social areas mentioned above, it is very important to secure proper protection of innovations (Durana et. al., 2020). Cooperation and mutual scientific relations play one of the major roles in efficiency of investments. Unfortunately, global pandemic of covid and war in Ukraine caused some serious strains in these relations. There are ongoing strict covid protocols in China, with significant impact on global economy. War in Ukraine caused strong economic contraction across whole Europe and put energy markets in chaos. Science in general plays a critical role in many fields and with sufficient investments should provide solutions, which would prevent future contractions of global economy. Apart from the beforementioned problems, science has also impact on our daily live through digital technologies (Zhuravleva et. al., 2019). Thanks to them, the connection between science and innovation is becoming more collaborative, even at the international level despite those problems. (Meyers et. al., 2019). Although the support of such a creative and innovative environment is more than necessary for the attractiveness of the economic environment and its development not only in Slovakia, but also in the entire European Union.

To be able to continue, it is important to understand the definition of innovation from different point of views. This term is little different for sociologists, economists, historians, or journalists. From a managerial point of view, it can be defined as a combination of two key elements: invention and change (Kral et al. 2019). Innovation is a source for every organization because it can bring change and in most cases is also driven by the technological capabilities of the organization, the ideas it can work with and the knowledge it possesses (Gailly, B. 2011). Joseph Schumpeter's basic theory of innovation formed in the 1960s defines innovation as a business intention to overcome customary methods of production, distribution and service in new ways that better meet customer needs (Moravcikova et. al., 2017; Sommerlatte, 2020). Another definition is offered by Oslo Manual, which defines innovation as the implementation of a new or significantly improved product (goods or service), or process, new marketing method or new organizational method in business practices, workplace organization or external relations (Jakimowicz and Rzeczkowski, 2019). At the same time, it also states that innovation can be introduced in any sector of the economy including government services such as health or education (OECD, 2022). In the 20s of the 21st century, the European Union considers research and innovation to be an essential part of the EU's coordinated response to the outbreak of the pandemic and energy crisis caused by Ukrainian war. It also considers innovation to be essential for supporting Europe's sustainable and inclusive recovery from both events (Hollanders, 2020). Considering current social changes, ecological requirements, and the intensification of global competition between regions with very different political and economic systems, there is the opportunity to observe how the development of society creates a new culture of innovation and society as such, including all its entities. From a macroeconomic point of view, innovations are important for the competitiveness of individual economies or regions on the international market (Frias et. al., 2020). From a microeconomic point of view, we monitor the competitiveness of individual entities within one region.

The scope of intellectual property is constantly expanding in its means to include new topics. However, this is not surprising given the constant changes in socio-economic conditions, technologies, and market opportunities (Kral and Janoskova, 2015). In the past, patents and copyrights represented privileges granted by monarchs to merchants, manufacturers, and artisans (Kachuriner and Hrushko, 2019). Over time, they became a form of personal property of inventors or authors. Currently, we can define them more precisely

as a class of intangible business assets of companies that perform the role of investor, employer, distributor, and trader (Zygmunt, 2019; Dutfield and Sustharsanen, 2008).

2 Methods

We decided to use WIPO's foreign databases for the purpose of this paper. These WIPO's foreign databases, thanks to its deep datasets helped us to evaluate the innovation potential of foreign entities. Major source of information and the basis for the research part of this paper was the database of the Industrial Property Office of the Slovak Republic (UPV SR) and also their annual reports published on the offices official website. The annual reports were a valuable source of information about developments in the Slovak Republic during the years 2009-2021. The database of the office enabled us to process, evaluate and compare the data necessary for the assessment of all entities applying for a patent.

The latest figures from the World Intellectual Property Organization (WIPO) on intellectual property activity worldwide indicate that 277 500 275,900 PCT international applications were filed in 2021, a 0,9% increase compared to 2020 despite the global pandemic (WIPO, 2022). On the other side, the growth of filled applications slowed down from 4% in 2020. The only positive remains that according to WIPO PCT applications have still an upward trend since 2010. The most PCT applications were filed by applicants from China, the USA, Japan, the Republic of Korea and Germany. The first 10 countries accounted for 88.1% of the total number of applications in 2021. This is depicted in Figure 1 bellow.
Figure 1. The biggest users of the PCT System applications.

Source: https://wbr.indprop.gov.sk/WebRegistre/

If we look at the kind of patents, then, we can state, that patent applicants from China and the Republic of Korea applied heavily for patents related to digital communications, while those from the US filed the most patent applications in the field of computing. Japan is mainly focused on electrical equipment and German applicants focus on the patents in transport.

Among the top innovators, we can find technological companies like the Chinese conglomerate Huawei Technologies, which filed the most PCT applications for 2021. It is

followed by Qualcomm Incorporated from United States, Samsung Electronics from the Republic of Korea and Mitsubishi Electric Corporation from Japan. Eight of the ten most significant innovators come from Northeast Asia. This is not a good sign for companies in European Union and their innovation potential hit by the pandemic and Ukrainian war, which will along with economic contraction have further negative impact on them.

3 Results and Discussion

In the following section, we evaluate the innovation potential of Slovak entities. The input was gained from The Industrial Property Office of the Slovak Republic and its annual reports along with WIPO datasets.

In order to better compare the innovation potential of countries, we have expressed the number of patent applications per million inhabitants in countries that WIPO designates as innovation leaders based on the total number of filed patent applications. We also drew data on the number of inhabitants from the World Bank database. It is important to note that newest information available were for 2020. These data are processed in the figure 2. To make overview more testifying, we decided to include applications from 2010. Figure 2, then depicts the number of patent applications filed by residents, divided by the total population of the country and multiplied by a million.
Figure 2. Resident patent applications per million population.

Source: World intellectual property indicators 2021

Republic of Korea is the unequivocal leader in the number of patent applications per million inhabitants. It is followed by Japan by a significant margin. Switzerland is in the third place. This depicts the country's high demands for technological sector of their economy. In the contrast to their first place in overall number of patents, China finished in the fourth place. The number of patent applications per million inhabitants in the case of other countries gradually decreases until they reach the value of 168 patents per million inhabitants in

Russian Federation. At the last, we can see the results of Slovak republic. The number of filled applications remained relatively unchanged through the last 10 years at 27 and 25 applications per million inhabitants during the year. This number is low in comparison to developed economies. There are many reasons behind this fact. Low investments in science and education, exodus of the most skilful young people to neighbouring countries and universities. Lack of motivation of these people to come back, because of high corruption and untransparent behaviour of state authorities or lack of modern, progressive, technological companies etc.
Figure 3. Number of patent applications, granted patents and PCT applications in Slovak republic

Source: https://wbr.indprop.gov.sk/WebRegistre/

Figure 3 shows a significant downward trend in the innovation activities of Slovak entities, but also of foreign entities on the Slovak market, especially on the curve of granted patents in the last twelve years. This happened despite the various marketing and PR activities of the UPV SR. If we look at the country of origin of the entities to which the patent was granted, these are mainly Slovak entities. Small part of them comes also from Japan, Czech Republic, United States and Austria. It is interesting that not all patents granted in the Slovak Republic in 2021 still had a valid legal status in 2022. The valid legal status expires if the patent applicant does not pay the annual fee, or if the approval committee evaluates it again and found out that the patent is not original and rejects such patent.

4 Conclusion

The period after 2009 defined the world economy, which tried to recover from the global financial crisis. Investments and productivity growth around the world, this was partially driven by innovations. In many cases innovations enjoyed faster growth than GDP itself. For example in 2020, this growth was mainly supported by the growth of key emerging markets, such as China, India, Korea, Germany, USA and Japan. The global innovation environment

is currently concentrated mainly in the eastern part of the world, in countries such as China, India, but also Vietnam and the Philippines, which are constantly on the rise. However, if we take into account number of inhabitants, then the clear leader is Republic of Korea. As many statistics further show, both developed and developing countries are increasingly monitoring their innovation performance and are working to improve it through spending and a persistent willingness to confront obstacles to national innovation systems. However, the world is currently facing unprecedented conditions of a pandemic and the threat of war global conflicts. These obstacles have an economic and social impact on all countries of the world at the same time. It should be emphasized that now more than ever, countries and communities are aware that innovation, especially in the search for medicines and vaccines, alternative energy sources and energy efficiency are the key for economic growth and safety. However, just like it was in the case of world economic crisis after 2009 and the following years, it will be important for economic growth to focus on the development of innovation beyond the field of health and energy by building sustainable and inclusive overall economic environment.

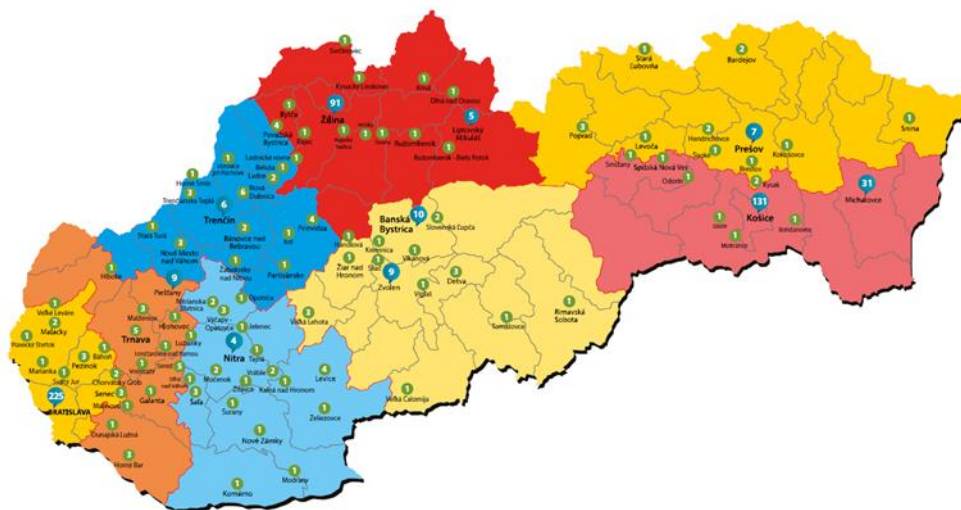
During the beforementioned period from 2009, the UPV SR consistently urged the need to increase investments in science and research. However, investments in Slovakia mostly did not even reach the value of one percent of GDP (approximately 0.88% of GDP). Despite some partial improvements in several years during the followed period, the situation remained bad. The Slovak government in the last two years decreased the financing of the science and research. This happened despite its already low state and despite the high cost of covid 19 pandemic for universities. Energy crisis caused by war in Ukraine put their financing in existence trouble and forced their executives to savings and announcement of education cancelation in the late 2022.


Figure 4. Number of patent applications in regions of Slovak Republic.

Source: UPV SR 2021 annual report

As we can see from the figure 4 above, patents applications are not distributed evenly around the whole Slovak republic. The most patent ideas come from the three cities with technical universities. Namely Bratislava, Kosice and Zilina. These cities are also regional centres for several well-known technological companies. This fact also depicts the importance of investments into science and research, because they are the main source of

innovation. Every crisis brings opportunities and space for its creative solution. One of the side effects of the current crisis is the stimulation of interest in innovative solutions not only in the field of health and energy, but also in areas such as remote work, distance learning, e-commerce, mobility solutions or carbon neutral economies (Zauskova et. al., 2020). These impacts have the potential to positively support the solution of societal goals such as reducing or reversing long-term negative climate change. For Slovakia, as for all countries coping with the pandemic and energy crisis, this period is a challenge to demonstrate the ability to increase its resistance to their effects and to overcome the crisis through fiscal incentives and fight against inflation.

Abstract

Research background: Isenberg created a broader, conceptual model and comprehensive framework for analyzing this system which he calls the self-sustainable entrepreneurial ecosystem. His well-known model covers six domains (namely policy, finance, market, culture, human capital and the supports) and a dynamism among them that represents a novel and cost-effective strategy for stimulating economic development. This strategy combines entrepreneurial vitality with a sustainable milieu.

Purpose of the article: This study aims to observe sustainability (CSR) and responsibility in the Hungarian SME sector based on Isenberg's entrepreneurial ecosystem model. We investigated the sustainability and responsibility orientation of actors to identify domains and connections and recognise collaborative innovation of sustainability opportunities in the Hungarian SME sector. Besides subjects' opinions were asked directly about the Isenberg model.

Methods: In the May and June of 2022, three focus group interviews were carried out with prominent professionals who represented the target population. Transcriptions were studied through broader content analysis using NVivo12 software.

Findings & Value added: As a result, this study provides an extension of Isenberg's model of entrepreneurial ecosystem tailored to the national SME sector. Our samples also emphasized that the model helps them to have a structured view that supports their work.

Keywords: *sustainability and responsibility; entrepreneurship ecosystem model; SME; qualitative analysis*

JEL Classification: *M12; M5; Q01; Q56*

> *"If you believe as I do that an entire ecosystem must exist in order for entrepreneurship to be sustainable – sustainability that ultimately exists without much central control is inherent in the concept of ecosystem—and*

have the positive impacts that it can have, then it logically follows that somebody should be responsible for seeing that the ecosystem evolves, and then exits." (Isenberg, 2011)

1 Introduction

The integration of entrepreneurship and sustainability plays a crucial role in national economies and is strongly related to globalization. Sustainability refers to the use of business practices in the internal and external, natural, economic and business environment. (Simatupang et al, 2016) Entrepreneurship is profit-oriented, and it can support both the economy and society only if it is successful (Isenberg, 2008). Unfortunately, companies may have a widespread negative impact on the entrepreneurship ecosystem. On the other hand, the success of entrepreneurship greatly depends on the ecosystem, which is created by a virtuous cycle of it. Several theories investigated the domains (factors) and mechanisms of this field. Therefore, entrepreneurial activities and entrepreneurs are integrated into a complex system with multiple actors. As Isenberg (2010) suggested, these elements are among others leadership, culture, capital markets, and open-minded customers—that combine in complex ways. He structured them into six domains that interact in very complex ways with the self-stunning entrepreneurship in the middle. However, each combination is unique but "in order for there to be self-sustaining entrepreneurship, you need conducive policy, markets, capital, human skills, culture, and supports." (Isenberg, 2011, p. 6) The whole system interconnects components that determine opportunities and pace for creating and scaling new sustainable businesses by entrepreneurs as Isenberg and Onyemah (2016) underlined.

Kansheba and Wald (2020) refreshed this study and suggested a research agenda. According to them, most papers about entrepreneurial ecosystems deployed a case study approach or conceptual work (without real empirical data). Only a few applied quantitative, qualitative or mixed-methods. In this view, our paper is gap-filling because our results rely on extended focus group analysis. Moreover, most of the articles have a too general focus. We targeted specific sectors, focusing on small and medium enterprises. This research aims to investigate the unique combination of the Hungarian entrepreneurial ecosystem in the SME sector in order to learn how sustainability and responsibility can be enhanced. The managerial and practical implications of our results may be useful for policymakers, managers and each actor who are responsible for sustainable development and want to change the dynamics of an ecosystem to progress sustainability and achieve innovation.

1.1 Environment based on the stakeholders' theory

The sustainable activities of companies are unthinkable without looking at the organisations, institutions, and people they are dealing with. The range of stakeholders has been examined in some academic works, and attempts have been made to group them according to different criteria. When looking at stakeholders, it is essential to distinguish between stakeholders with influence (and thus power) and those who are merely interested. Differences in the strategic environment of organisations also significantly impact who the stakeholders are. Consideration must be given to the industry, political, social, and technological context when looking at the range of public and private actors.

According to Malecki (2018), an entrepreneurial ecosystem also includes numerous stakeholders, and various models and theories describe differently these ingredients. In our paper, we relied on one of the allocation options which was formulated by Freeman in 2002 (Freeman, 2002) when he suggested that firms redistribute benefits and necessary decision-making powers among all stakeholders based on their contributions. This would redefine the

impact of stakeholder scope on organisations. In further research, he and his co-author concluded that all stakeholders could be divided into two groups. They named these two groups cooperation and collaboration. Cooperation is the group of people who are affected by or have a stake in the business; collaboration is the group of people whom the industry needs support, such as employees, suppliers, and customers (Dunham et al., 2006)

Another approach divides the stakeholders of a company by looking at three characteristics. The presence or absence of the attributes of power, legitimacy and urgency among the stakeholders assigns stakeholders with the same traits to a group (Mitchell et al. 1997).

The third theory we applied is that stakeholders can be divided into two broad groups according to whether they are involved in the company's internal operational processes or external contributors. Organisational learning and collaboration play an essential role in this division. The corporate learning process facilitates the flow of implicit and explicit knowledge that improves the effective functioning of the organisation. On this basis, we can distinguish the following types of learning:

- internal stakeholders: owners, managers, employees
- external stakeholders: suppliers, customers, competitors, strategic partners, public institutions, local communities, and creditors (Jones, 1995)

Our study aims to map the mindset and actions of the leading actors in the SME sector in this field, whether consciously or unconsciously mentioned by our subjects.

The concept and understanding of CSR have been evolving since its appearance in academic works in the 1930s, in the wake of the Great Depression. Today, its scope has broadened and ranges from compliance with corporate laws to aligning internal business objectives with externally determined societal aspirations (Győri et al., 2021). Unfortunately, the relevance of this multidimensional concept within the SME sector remains weak and is overshadowed by its application in large and multinational organisations. SME actors are under increasing pressure to participate in social activities as if they were no different from their larger counterparts.

Some theorists argue that economic interests take precedence over social values. At the same time, other researchers believe that CSR is the firms' response to issues beyond the firm's narrow economic, technical and legal boundaries (Davis 1973).

Table 1. Stakeholders and codes

	future generation		

Source: own elaboration based on the literature

Further exploration of the field and its relationship with sustainability and the ecosystem led us to conclude that the scope of stakeholders should be further broadened and disaggregated for the sake of this research. As we believe that current and future impact are

essential aspects of sustainability, we have further disaggregated some elements and identified future generations as stakeholders to complement this feature.

1.2 Isenberg's model

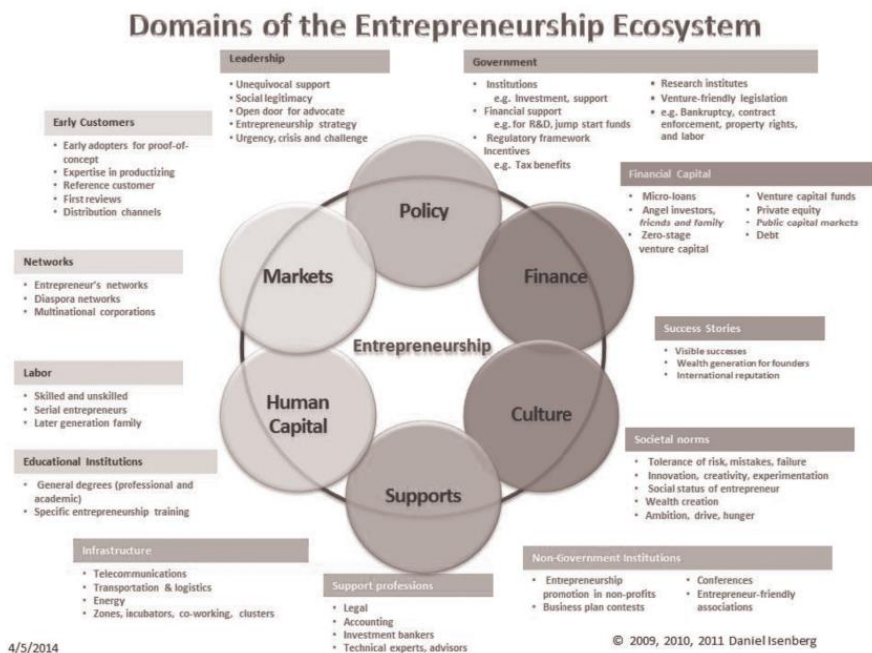
In 2002, Hedstrom and Michael Isenberg, at that time the two consultants began their paper with the following sentence "Massive shifts are underway in how business relates to society." (p. 13) They identified the five main forces that "will spur an unprecedented degree of innovation and define the successful businesses of the next 20 years." (p.13.) Listing several big companies as examples, the redline of sustainable and conscious entrepreneurship was drawn in that article. Later, Daniel Isenberg who was a professor for 11 years at the Harvard Business School and has been an entrepreneur and venture capitalist (active angel investor) in Israel, became famous for the concept and development of entrepreneurship ecosystems. However, Daniel Isenberg identified entrepreneurial ecosystems at the national scale; nearly all his examples are small countries because this is the most appropriate for studying entrepreneurial ecosystems but some network links, participants (domains) and resources (specific technologies) are global.


Figure 1. Domains of the Entrepreneurship Ecosystem

Source: Isenberg and Onyemah (2016, p. 74)

Daniel Isenberg published his findings and theory about the entrepreneurial ecosystem in the 2010s when created (as he says for convenience's sake) his model (see. Figure 1). The author has taken the ecosystem metaphor directly from the natural sciences (Isenberg, 2016) and calls it idiosyncratic because elements are interacting in highly complex and idiosyncratic ways that cannot be transferred among or copied by various regions. What makes the ecosystem unique? Firstly, the regional available resources, secondly culture, then the actors and the dynamics among them. (Baron & Freiling, 2019) That is why the diagram lacks causal paths as Isenberg (2010) said there are no arrows indicating what causes what. An

ecosystem is a dynamic, self-regulating network of many different types of actors. In every entrepreneurship hotspot, there are important connectors and influencers who may not be entrepreneurs themselves. Isenberg organised them into six main domain fields, which are Culture, Markets, Human Capital, Finance, Supports, and Policy.

Actors of the Entrepreneurship Ecosystem

Market access
- Corporate executives
- Distributors
- Export agencies
- Trading company executives

Government
- Elected: Mayor, governor
- Elected: Legislators
- Regulators
- Gov't research directors
- Innovation agency managers
- Bankruptcy officials
- Economic dev't directors

Policymakers and public leaders

Corporations

Financial actors

Financial actors
- Bankers
- Family offices
- Venture capitalists
- Leasing managers
- Non-bank lenders
- Grant-givers

Growth Entrepreneurship

Educators, human capital
- University heads
- Entrepreneurship dept, heads
- Leaders of training centers
- Service professionals

Educators and developers of human capital

Culture impacters

Support organizations, event organizers

Entrepreneurship supporters
- Event organizers
- Incubator directors
- Mentors
- Foundation managers
- NGO managers

Culture impactors
- Journalists
- Popular cultural "icons" (e.g. athletes)
- Popular bloggers, social media
- Informal opinion leaders

© 2016 Daniel Isenberg

Figure 2. Actors of the Entrepreneurship Ecosystem

Source: Isenberg and Onyemah (2016, p. 75)

As Malecki said, "Although empirical research by economic geographers historically has focused on large firms as employers and as agents of globalization, large firms typically start small and attract interest only after they become large." (2018, p. 1) Isenberg and Onyemah also underlined this development, "The common denominator among entrepreneurship ecosystem elements is their essentialness for increasing numbers of companies growing more and more rapidly. (2016, p. 73)" It means a so-called "spillover effect" will lead to the globalization of entrepreneurship.

The ecosystem model makes it possible to establish an environment, securing implementation for the principles of sustainable development (those are expressed for example in the SDG 17 goals, United Nations, 2015) and shows how increasing self-interest could develop better solutions in the future (Hauber & Csongrádi, 2015). Tolstykh et al. (2021) underlined that regional sustainable development is focused on achieving firstly ensuring a sufficient level of quality of life for the regional population. Afterwards, it should relate to sustainable development goals at the supra-regional (national and global) level.

2 Methods

2.1 Focus group

Our research is in its exploratory and hypothesis definitions phase, so the observed focus groups are prior research to develop a structured and systematic survey based on a more detailed and sensitive understanding of the topic. (Wilkinson, 1998) Therefore, we designed and used guidelines based on previous literature studies. Isenberg's model was directly implemented into the guideline (see Fig. 1). In this paper, we only investigated (1) codes related to SME sectors' stakeholders mentioned in the text and (2) subjects' direct responses and opinions about Isenberg's model.

Three focus group meetings were organized where the same moderator asked the same questions based on a preprepared guideline. The guideline was validated in a pilot round. Each meeting was recorded, and conversations have been transferred to three transcriptions. In this study, we focused on (1) codes about the SME's stakeholders whereby codes were directly generated from the state of the arts. Two independent researchers coded the entire text. Finally, (2) the selected sections from the transcriptions were studied to align with the 5th topic when subjects were directly asked about Isenberg's model. Transcriptions were investigated through broader content analysis using NVivo12 software.

Source: Own elaboration

As for our target population (i.e. the Hungarian leaders from the SME sector) and regarding the research aim (sustainability and responsibility), three focus group interviews were performed with prominent professionals who represented the target population.

2.2 Evaluation methods

Onwuegbuzie et al. (2009) summarized various methods of how focus group transcriptions can be analysed. Following their suggestions, we used classical content analysis when after we created codes based on the literature, data was separated into smaller chunks and each chunk was placed in the codes. Finally, these codes are grouped, counted and quantified by NVivo12 Software. So-called quasi-statistics refer to the use of descriptive statistics that can be extracted from qualitative data. Additionally, semi-discourse analysis was also carried out, in order to understand social interaction and cognition, when the representative or unique lines and segments of transcription were selected to examine how versions of the elements (here opinions, best practices, and attitudes) emerge in conversations. Semi-discourse or

thematic analysis means that basically major themes were organised and evaluated. Separately two researchers did the coding and content analysis, its reliability was tested with the Kappa index and agreement percentage and both showed strong agreements and matching (the "stakeholders" codes covered 95.62 % of both codings).

In both cases, the so-called keywords in context method were also carried out in order to determine how prominent leaders from the Hungarian SME sector use expressions and words regarding sustainability and responsibility. It is essential to study how our target population communicates on a daily business basis. Therefore, a better survey may be created knowing the culture of the use of keywords.

3 Results

3.1 Classical content analysis

In our focus groups, we wanted to find out how the managers and owners of SMEs perceive responsibility, what motivations accompany their activities, and how personal values influence how they operate. Do they integrate responsibility and sustainability into their daily activities, or do they deal with this issue on an ad-hoc basis?

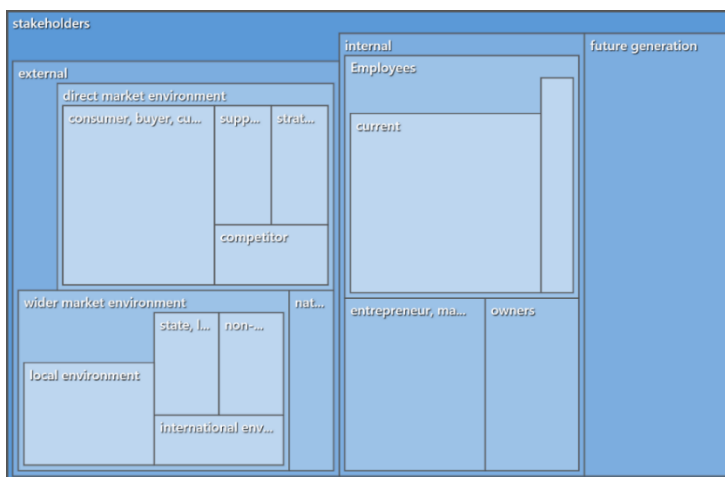
By comparing the appearance of each code, we can observe that among the internal environmental elements, the personal values of the entrepreneur, manager, family, and owner strongly influence the approach. The natural environment was emphasised during the interviews among the external environmental factors. In addition, the impact on future generations and the responsibility of the business in this regard were frequently mentioned. The figure includes the views of each focus group member, where they talk about the area of the respective code. Darker colours indicate an increase in the number of mentions.


Figure 3. Code frequency

Source: Own elaboration

We have analysed the relationship between the codes based on the opinions of the surveyed entrepreneurs. The relevant parts of the interview extracts were assigned to the corresponding regulations. This coding was done in parallel, and the results were then cumulated into a single file, thus minimising the potential bias of our individual researcher's opinion. We based our measurements on the Jaccard index, which measures the similarity of set samples. We found that the codes can be sorted into four major clusters. The first cluster

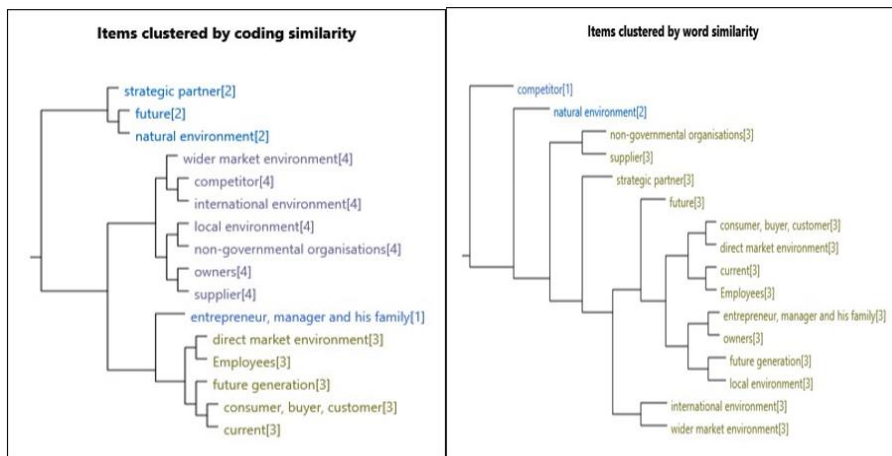
is distinct from the others by one element, i.e. we can conclude that family values and traditions strongly influence leaders and that where sustainability values are also present in the leader's family, they are more strongly current in the company's operations. The elements in this code are distinct from other areas. A separate cluster of strategic partners appears for the future and the natural environment, which were mentioned in a similar context and felt interrelated by the interviewees. The primary market, the employee, the customer and the future generation, who also appear in these two groups, were placed in the third cluster. This shows that these codes appeared in the same texts and similar contexts, i.e. the managers perceive these elements and stakeholders as belonging. According to the literature, all other elements were placed in the fourth cluster, whether internal or external stakeholders. This may be because members of the SME sector are often vulnerable in their role as suppliers and have substantial market exposure in Hungary. Thus, these elements are perceived not to influence them. However, it is interesting to note that the local environment is also included in this cluster. Further research is needed to investigate this.


Figure 4. Dendrograms of the codes

Source: Own elaboration

The same co-occurrences were examined using a similar analysis technique for word similarities. In this result, we observed differences from the code tree. Interestingly, the word similarities show complete separation of competitors, presumably because one of the most significant pressures comes from this area. After all, there is massive competition in the SME sector. The natural environment is a separate cluster. It was clear to all participants that this was an important issue. Due to the aim of the research, the discussions also revealed that sustainability and responsibility obviously was the first and most common area that came to the minds of the interviewees. As a result of our analysis based on word similarity, we identified 3 clusters. The remaining items showed strong co-occurrence, described by similar words in the same context.

3.2 Thematic analysis

When the moderator directly asked for participants' opinions about the Isenberg model (Figure 1 was shared). It can be concluded that most of the interviewed SME managers are not familiar with the model. They found challenging to identify the schematic model at first glance. *"I got problems with this chart." (János), "My problem is that there are very different effects and counter-effects within each point, so I know how to balance, but every domain*

has different components and obviously this cannot be separated"(Edu) "I am struggling with this figure, could you please repeat your question?" (AutoSave) However, Isenberg published this model also for managers, the first reactions, acceptance and understanding of the model were ambiguous.

After a wider clarification, it turns out that discussions can be clearly associated with the main aim of the ecosystem theory, even if they call domains differently. Their frequently used expressions show how actors perceive the Hungarian ecosystem and which domains are emphasized in their communication. In the section the following frequently used expressions occurred:

- Nationality (*Hungarian*) was mentioned 21 times in the section,
- *Culture* appeared 18 times,
- *Sustainability* 17 times
- *Politics* 18 times
- *Family, kids, parents, home, flat,* also regularly mentioned

The dynamics among the actors are intense and not just static, thus the time element (future and past) seems to be also important. Heritage from the past, how the subjects are educated or where they were raised (e.g. "*What motivates you? - I think I brought this from home." AutoSave*) and the next generation ("*This is not the case with our children, they were born into an environment that is not bad in Hungarian terms. However, moving on from there is not so easy. Obviously, they experience it in tiny steps" István*) or possible new actors and future projections and expectations are also regularly mentioned in the text. *"Only the consumer society produces that the needs have changed, so, unfortunately, I look at the development process of my own children. Due to the fact that I want it to be as good as possible for my own children" Lasek*

Dynamics within and between the domains (i.e. the way how ecosystem actors behave and interact) are imbued with emotions and feelings. *"That is typical Hungarian." Lasek* For example, the sentiment of Hungarian always contains some stereotypes and prejudice (see Fig. 5). "*The Hungarians like to cry, they always say this, and say that, if they were serious, we would not be an entrepreneur so we would have failed a long time ago*." *János*

Additionally, institutional settings like tax environment or grants or complex capital structures as part of the Hungarian business culture appear in the conversations.
Figure 5. Text tree around the word *Hungarian*

Source: Own elaboration

The impact and importance of the personal inner circle like family and relatives are underlined, as well. *"We also have family roots, they say, because the goodwill clearly comes from there."* Gábor or *"If I didn't have a supportive family environment, I wouldn't be able to get from one to two, because I'm tiny and I'll stay tiny."* Evedor

Finally, best practices and examples show how routines are going and how SMEs are doing for a sustainable future like in this final quote as a beautiful example of local patriarchy. *"Also about taking responsibility: the flower store is in my village, right? So that's how we get into everyone's lives and since I'm an economist, I'm not from a family with such a history of flower arranging for a thousand years, so I took what I liked and what I liked from all of this. And this is how we educate the village from this point of view. I mean we teach what is appropriate, what is not appropriate, what is sustainable, for example why flowers are not wrapped in cellophane. .... we also have special selections, from the local ceramicist, the local artist, or from the local I don't know what... and I tell everyone who made the product and I'm sure everyone will figure it out... then it considers as a small community building.... it takes half a year for the new tenants to learn that we say hello and greet each other, not because we know each other, but because we live here together. ... it turns into such a small community, ..., I am happy to take responsibility so that is how we can think together, and how this can really be done, starting with the selective collection. We have a very large institution with hundreds of people, a home for the mentally disabled people, and in the village, it is a common sight for the children to see all kinds of people with limps and all kinds of people in wheelchairs, people who can't speak, can't count, but we'll solve it together. For example, a deaf-mute people lives there who always comes into the store. When he gives his wallet, then I'll do the math. Usually, I don't understand what he's saying, so he shows and mimics everything to me. There are some other disabled people, the children know them, the village likes them too… There is another man. We give him work so that he can collect the selective trash, and he comes over and picks out ours, like he takes the plastic bottle away, then gets a bunch of flowers for it, which he gives to his beloved. …"* Evedor

4 Discussions

The novelty of this study arises from the integration of theory and managerial implications, where policymakers, stakeholders, entrepreneurs, and the whole socioeconomic environment for sustainable entrepreneurship activities may achieve a successful and long-term committed sustainable future. An important result of this research is the understanding of how Hungarian SME leaders are thinking about sustainability and which components and domains can influence their sustainable activities in order to promote innovative sustainable development. A nation with fewer environmental restrictions can force some companies to manufacture offshore, in this term sustainability and globalization may be used to describe competitive advantage, not the environment. Higher degrees of legislation and collaboration, and information exchange are likely to facilitate more favourable entrepreneurship environments worldwide. Clear regulations, open communications, and cultural values (like trust) may help stakeholders to collaborate effectively within the system and to work with external domains and progress sustainable development practices more actively in the SME sector.

Maroufkhani et al. (2018) provide a systematic review and a possible extension of Isenberg's model of entrepreneurial ecosystems. Based on an extensive literature study, they added domains of crowdsourcing and industrial dynamics to Isenberg's conceptual model. Based on our findings, family and personal backgrounds (like education, where and how people are raised and parental behaviour and values) are highly important parts of this model and may be implemented into the Supports domain.

Web-Based Geographic Information Systems as a Part of Digital Environment in the Age of Globalization – a Case Study

Jitka Komarkova[1,*], *Martin* Kratky[1], and *Ondrej* Mach[1]

[1]University of Pardubice, Faculty of Economics and Administration, Institute of System Engineering and Informatics, Studentska 95, 532 10 Pardubice, Czech Republic

Abstract

Research background: Globalisation and governance are linked concepts. Globalisation influences quality of governance. Good governance can increase interest of global companies in particular regions or countries. Good governance is pre-condition for sustainable development. Many decisions made by public administration are spatially oriented. Web-based GIS solutions have been increasingly preferred to allow easy and intuitive access to spatial information and to involve citizens in the decision-making process.
Purpose of the article: The case study provides an overview of progress in the utilisation of web-based GIS by chosen municipalities in the Czech Republic to inform or include citizens into public activities and affairs, e.g. fault reporting.
Methods: Case study based on spatial analyses. Visualization of results using cartographic methods. The diffusion of innovations theory, as proposed by Everett Rogers, serves as a background.
Findings & Value added: Case study demonstrates the diffusion of innovations in practice. Two former districts in the Pardubicky region are chosen for the case study. Municipalities of various size are covered. Contemporary diffusion of web-based GIS solutions is compared to the diffusion in the year 2018. Some results are visualised by maps. Discussion of success factors is the key added value.

Keywords: *diffusion of innovations; eParticipation; Web-based GIS; good governance; digital environment*

JEL Classification: *R59; H83; D83*

1 Introduction

The age of globalization has introduced many new approaches and technologies to improve our lives. Citizen participation can be given as an example. It supports participation of citizens in decision-making and planning processes at various levels of government. It is possible to actively participate in decision-making processes, which does not refute

---

* Corresponding author: jitka.komarkova@upce.cz

representative democracy and its principles, but on the contrary promotes the interconnection of local government and citizen (Tomor, 2019; Irvin & Stansbury, 2004). Participation can be divided into several levels, depending on how actively local government and citizens are involved in the system. The level of citizen involvement can be described by the term *participation ladder*, which represents the progression from the lowest participation of the citizen to the highest. The foundations were laid by Sherry Arnstein (1969). One of the lowest forms of the participation ladder is information, which is only a one-sided communication of the local government to the citizens. Information can be done in several ways. For example, in the form of a public hearing or a panel discussion. The opposite pole, that is, the highest form of citizen participation, is the delegation of decisions into his hands. This form is often not used in the Czech Republic. The only exceptions are local referendums. Over the years, the participatory ladder has been modified by many authors (Rocha, 1997).

For citizen participation, it is important to choose the right technologies to help meet the desired goals. According to Chmelařová et al. (2020), the devices that public administration and citizens can use include smartphones, tablets, laptops, desktop computers. Their suitability of use depends on criteria such as variability and device characteristics between a smartphone for simpler tasks and a desktop computer for more complex tasks. It is also important to choose the right form of communication between the devices of citizens and the public administration. This choice depends on many factors, such as the type of device, the form of participation, the type of application, and so on. Examples of participatory technologies, according to Csáki (2020), include online petitions, public opinion polls and others. Based on these factors, it is selected whether the application on the device will require a permanent connection to the Internet and thus to public administration, or whether the application is allowed to operate offline and data from it is synchronized occasionally (Szarek-Iwaniuk and Senetra, 2020).

One of the newly explored areas for promoting participation is blockchain. According to Shrier (2020), blockchain can be thought as a database that is distributed among users and contains all records since its inception. Jafar et al. (2021) states that each blockchain network has its own characteristics and attributes that determine its usability for different projects. Muth et al. (2019) gives an example of the interconnection of blockchain and public administration in the form of a cadastre of real estate. According to the authors, this system would reduce real estate fraud or embezzlement of money. According to Jafar et al. (2021) e-voting is a potential use of this technology This system could reduce the cost of printing ballots and could increase voter turnout, as it would be possible to vote from anywhere. However, these solutions bring new threats such as digital cybersecurity and it would be necessary to introduce regulations and standards for the solutions (Jafar et al., 2021). Bagloee et al. (2021) devotes other potential uses of blockchain in their work.

One of technologies already in use are Geographic Information Systems (GIS). GIS combines spatial data, tools and geoinformation technologies to help citizens participate in the functioning of the city (Kotus and Rzeszewski, 2020). They are crucial in some areas of local government functioning, such as spatial planning (Kahila-Tani et al., 2019). Nowadays, web GIS is used in most cases – these versions are most often referred to as WebGIS (web geographic information system), which includes well-known geoportals (such as public administration geoportals). Geoportals allow access to and handling of geographic information via the Internet (Lafrance et al., 2019). Often these services are provided by public authorities. This information is mainly public and provided free of charge. Geoportals allow data to be viewed, analyzed, and edited through a web browser that the user is familiar with. Geoportals offer features that the user needs for their work, so they cannot make a mistake based on unfamiliarity of GIS (Komárková and Kupková, 2018).

The main aim of the paper is to evaluate how GIS are used by municipalities to inform or include inhabitants in citizen participation.

2 Methods

Form of a case study is used. The case study deals with municipalities of the second and third type in the Pardubice region. Municipalities are the basic self-governing units in the Czech Republic and are divided into several types according to the law. These are:

- municipalities with a regular municipal office (municipalities of the first type),
- municipalities with an authorized municipal authority – (municipalities of the second type),
- municipalities with extended competence – (municipalities of the third type).

In total, there are 26 municipalities, including the regional capital Pardubice. As part of the study, it was examined whether the municipality operates a map portal (geoportal) and allows citizens to view spatial information about their municipality.

Another monitored area of participation is the methods of fault reporting. It was ascertained whether the municipality operates a platform where a citizen can report defects and suggestions in the territory of the municipality. Fault reporting can take many forms. These include, for example a form solution, which represents the most basic option, where a citizen fills in a form via a web browser, which may contain various specifications (e-mail, place of reporting, description, or possible insertion of a photo). Such a form is accessible through the website of the municipality or through the website of technical services of a particular municipality. WebGIS solution. An application that allows you to enter and locate fault reports on a map. The solution can be a standalone application or as a module part of a WebGIS application (geoportal). Another option is a mobile application in a smart device that can use the geolocation of the device, allow you to take a picture of the fault and then upload it. The application can work independently or be a complement to the WebGIS solution. Municipalities can combine these different implementation methods and possibly use more solutions. For example, technical services may have a form solution where crowded trash cans are reported, but the municipality also has a WebGIS solution where people can write suggestions for potential changes in public space.

3 Results and discussion

The survey found that out of a total of 26 municipalities, 19 (73%) are using some form of web GIS as of 28 February 2022. Among these solutions are Marushka (https://www.geovap.com/cs/marushka), GePRO (https://www.gepro.cz/produkty/geoportal/), GObec (https://www.gobec.cz/mapovy-server/), ArcGIS (https://www.esri.com/en-us/ArcGIS/products/geoportal-server/overvie), GIS4U (https://www.tmapy.cz/gis4u), Cleerio (https://www.cleerio.com/cs/mapova-aplikace) and custom solutions. Almost half of the municipalities of the second type do not use any geoportal. A more precise overview between municipalities of the second and the third type is shown in Table 1.

Table 1. Overview of geoportals in municipalities of the second and third type in Pardubice region

Geoportal	Second type		Third type		All municipalities	
	Count	[%]	Count	[%]	Count	[%]
Marushka	1	9,09	6	40,00	7	26,92
Gobec	3	27,27	3	20,00	6	23,08
GePRO	1	9,09	1	6,67	2	7,69
ArcGIS	0	0,00	1	6,67	1	3,85
GIS4U	1	9,09	0	0	1	3,85
Cleerio	0	0	1	6,67	1	3,85
Custom	0	0	1	6,67	1	3,85
None	5	45,45	2	13,33	7	26,92

Source: authors

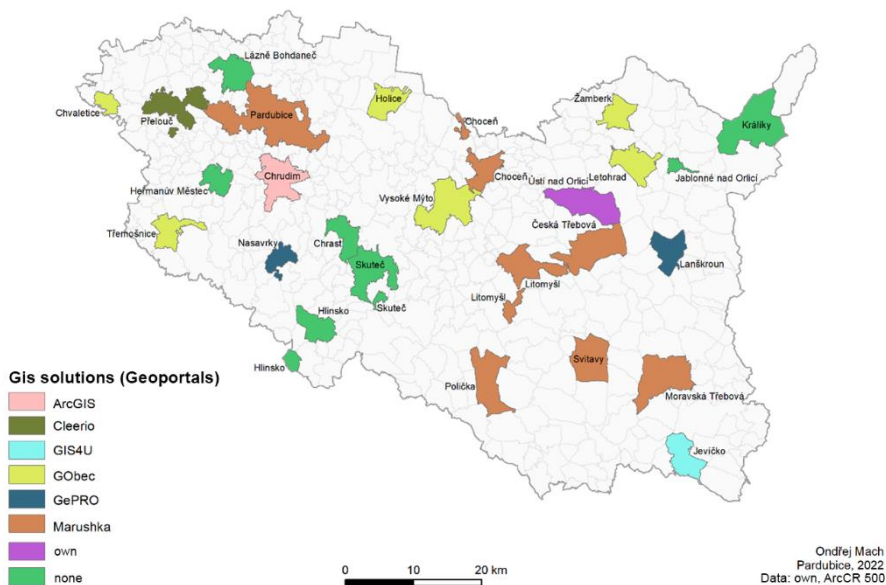
The geographical distribution of municipalities is shown in Figure 1.


Figure 1. Web GIS solutions (Geoprotals) in municipalities of the second and third type in the Pardubice region.

Source: authors

Out of a total of 26 municipalities, each (100%) used at least one method of faults reporting. The used solutions include form solutions (the municipality's own solution), Marushka, ZmapujTo (https://www.zmapujto.cz/), Mobilní rozhlas (https://www.zlepsemecesko.cz/), GObec, DejTIP (https://dejtip.eu/) and T-mapy (https://www.tmapy.cz/hlaseni-zavad). ZmapujTo (web solution) and Mobilní rozhlas

(mobile application) work together (except for the city of Pardubice – they do not use Mobilní rozhlas). Marushka, GObec, T-mapy and DejTIP are WebGIS solutions, but they also have their own application that municipalities may or may not use.

The most widely used solution ZmapujTo is used by 16 municipalities (62%). The second Mobilní rozhlas (with active fault reporting) in 15 municipalities (58%). The third most used solution is the form used by 11 municipalities (42%).

Figure 2. Overview of fault reports (and their combinations) in municipalities of the second and third type in the Pardubice region.

Source: authors

The newly obtained data from February 28, 2022, was compared with the work of Komárková and Kupkova (2018). In this work, a similar issue was being solved, in which was then possible to observe the development after four years.

After comparing the current data of municipalities with the authorized municipal authority with data from 2018, it is found that 9 municipalities still operate a geoportal, one municipality stopped operating the geoportal (probably caused by a change in the geoportal operator). 3 municipalities began to operate the geoportal (improvement of 20%) and 2 municipalities do not have and did not have a geoportal.

As part of the participation in the area of fault reporting, it was found that 9 municipalities still operate fault reporting, no municipality has cancelled fault reporting, 6 municipalities have started to use fault reports since 2018 (improvement by 40%).

All investigated municipalities support a system for fault reporting.

4 Conclusion

Digital environments play an increasingly important role in the age of globalization. For example, a suitable environment can significantly support and fasten cooperation of remotely located teams or citizens participation.

The paper aimed to evaluate changes in utilization of digital platforms used to support citizens participation since 2018. It revealed that some services are not in use but on the other hand some new services have been deployed.

The study focuses only on the Pardubicky region, the Czech Republic which can be understood as its limitation.

For the future, authors plan to observe next development to identify changes and new trends in utilization of participation technologies.

Specification of methods for public passenger transport performance and efficiency evaluation

Veronika Komorousova[1,*,] *Lilia* Dvorakova[1], and *Marie* Cerna[1]

[1]University of West Bohemia, Faculty of Economics, Univerzitní 8, Pilsen, Czech Republic

Abstract

Research background: The public passenger transport sector has its own specifics, due to which traditional methods and approaches cannot be used for performance evaluation. The choice of metrics for performance and efficiency evaluation can therefore be problematic and ambiguous.

Purpose of the article: The purpose of the research is to perform, based on a systematic literature review, description of the methods and metrics used for performance evaluation in the public passenger transport sector.

Methods: Systematic literature review was performed based on the selection of the articles provided by Web of Science database which relevant issue was performance and efficiency in the public passenger transport. Articles were categorized according to criteria and a description of the thematic focus of the articles was made. Subsequently, an evaluation of the methods and tools used for performance and efficiency evaluation was carried out. Within the framework of the methods used, the measures and criteria for the efficiency evaluation were structured.

Findings & Value added: The findings were summarized in the conclusion. Based on these findings was confirmed that there are no uniform metrics and models for public transport efficiency evaluation. In this area was identified a large number of criteria that influence the efficiency of public passenger transport.

Keywords: *public passenger transport; performance; efficiency*

JEL Classification: *L91; O18; O57*

1 Introduction

In its most general form, the concept of business performance is used in connection with the definition of the very essence of the existence of the business and its success and ability to survive in the future (Fibírová & Šoljaková, 2005). Performance can also be defined as "the ability of the company to evaluate the investments made in its business activities in the best possible way" (Faltejsková et al., 2016).

In a market economy, the financial position and performance of the company have to be constantly evaluated. Various performance benchmarks serve as feedback for companies that

---

* Corresponding author: vkomoro@kfu.zcu.cz

evaluate their decisions and allow them to adjust direction or eventually reverse the identified situation (Tousek et al., 2021).

Properly designed performance measurement system provides the basis for effective management system and can be used as a management tool for strategic, tactical and operational business management (Knápková et al., 2011).

Each performance measurement model is different and uses different indicators. However, these models also have some common features. Most authors try to strengthen the predictive capabilities of the original models as a response to changes in the economic environment (Hyranek et al., 2018).

Performance measurement contains these separate questions: How to measure the inputs and outputs of the business process? How to compare them, for which user is the performance measured? Who is requesting this information and why? (Fibírová & Šoljaková, 2005)

Among the traditional indicators of financial performance are primarily included classic indicators of financial analysis based on accounting data - i.e., primarily absolute profit indicators and profit rate indicators (profitability). The fundamental problem is above all the fact that these indicators cannot exist without additional information relating in particular to the development of liquidity, indebtedness, the relationship between the property and financial structure or the use of the company's assets, or other indicators focused on the level of productivity, added value, cost effectiveness and capital market indicators (Knápková et al., 2011). Another obvious, problematic and questionable fact of financial analysis indicators is the issue of the explanatory power of input data (i.e., accounting statements).

The development of modern methods of business performance evaluation responds to the described deficiencies of traditional methods and takes into account also non-financial indicators. Modern methods include, for example, the EVA indicator (Economic Added Value), which works with the concept of economic profit, as well as the Balance Scorecard (BSC) model, which works with incorporating business processes and their successful management, and the Excellence Model (EFQM), based on the logic that excellent results can only be achieved by the organization under conditions of maximum customer satisfaction. Furthermore, there belongs, for example, the Perofmance prism model (PPM), which evaluates the company's performance using five perspectives: strategy, options, processes, satisfaction and contribution of interested groups. On the contrary, the purpose of another model (Performance evaluation pyramid) is to link organizational strategy with its activities (Narkuniene & Ulbinaitė, 2018).

The public passenger transport sector has its own specifics in relation to performance, due to which it is not possible to use commonly used methods and approaches for performance evaluation. A transport system that allows people to satisfy their needs at the lowest social cost can be considered efficient.

In order to assess the efficiency of the transport system, it is necessary to include all persons travelling or being affected by transport, as well as all social and external costs associated with transport (called externalities). Benefits and costs are usually understood on a broader scale than revenues and costs from an accounting perspective (Marešová, 2012).

In connection with the efficiency of public passenger transport, it is also necessary to mention the basic principle of 3E (economy, efficiency and effectiveness). The 3E principle is often associated with performance in public administration.

Žižka (2017) within the evaluation of the efficiency of public transport in the Czech Republic distinguishes three levels of efficiency and states that efficiency is understood as the ability of society to achieve set goals. On the other hand, efficiency (effectiveness) is understood as the relationship between the input used and the output achieved, and economy then means avoiding waste in business process implementation, which means procuring input at the lowest possible cost. The overall performance is then determined by the combination of all three components mentioned above.

2 Methods

The systematic literature search was carried out based on the results of the search in the Web of Science database. Total of 323 articles was found using the research based on the keywords: public transport, efficiency and performance. (Articles published in the years 2008–2021, where the main relevant topic was performance and efficiency in public personal transport.) The articles were sorted and categorized, and then evaluation of the methods used for performance evaluation was carried out. The measures and criteria for the efficiency evaluation were structured, and a description of the thematic focus of the articles was carried out.

Table 1. Analyzed research sources by the period

Year of publication	Share of articles in %
2020-2021	19 %
2018-2019	33 %
2016-2017	18 %
2010-2015	24 %
2008-2009	6 %

Source: own processing

An overview of the analyzed articles according to the period in which they were published is shown in table 1. The largest share of articles falls in the period of 2018–2019. On the contrary, the fewest of the analyzed sources were published in the period of 2008–2009.

3 Results

With regard to the focus of the articles having something to do with the area of transport systems (tab. 2), most articles were focused on research on public passenger transport in general (42 % of sources), followed by the area of public bus transport (30 % of sources). 22 % of the resources were focused on city public transport research and only 6 % of resources were dedicated to railway transport research.

Table 2. Researched transport systems

Type of the transport system	Share of articles in %
Public bus transport	30 %
City public transport, metro	22 %
Public passenger transport in general	42 %
Railway transport	6 %

Source: own processing

Taking into account selected sources, it can be stated that most of the articles were focused on research of transport system in the Europe (42 % of articles). This was followed by the research in China and India, 18 % of articles were focused on another non specified

regions and 9 % of the articles were focused on the analysis of the transport systems in greater number of countries.

Table 3. Region in which was researched the transport system

Region of researched transport system	Share of articles in %
Europe	42 %
China	13 %
India	12 %
global view	9 %
America	6 %
other	18 %

Source: own processing

3.1 Thematic focus of the articles, research methods overview

In the table number 4 is the overview of thematic focus of analyzed articles. 39 % of the articles were generally focused directly on analysis of efficiency in public passenger transport. In this area was then some topics defined in more narrow context. There were articles focused on technical, operational or environmental efficiency or articles focused on the efficiency of the services provided. In the analytical part, there was also a variance in approach. In some cases it was directly about the construction of an efficiency model, other articles focused on the compilation of a matrix or an overview of criteria/indicators. In 33 % of the articles, the authors focused on investigating the influence of a certain factor on efficiency. This factor was, for example, the ownership factor, the environmental factor, or the network morphology factor, the transport integration factor, managerial attitude, etc. Another 9 % of the articles were focused on the analysis of the transport network, its morphology and integrity. Other analytical studies were focused, for example, on the influence of factors on CO_2 emissions in transport, analysis of passenger satisfaction, etc.

Table 4. Thematic focus of the articles

Thematic focus of the articles	Share of articles in %	More detailed aspects of the topic
Efficiency analysis	39 %	Technical efficiency, operational, environmental, efficiency of services, optimization, criteria matrix model
Effect of a certain factor on efficiency	33 %	ownership factor, environmental factor, network morphology factor, transport integration, managerial attitude, PPP factor, form of contractual relations
Analysis of the transport network, integrated transport system	9 %	
Other analytical studies	13 %	Influence of factors on CO_2 emissions, passenger satisfaction analysis, bus battery operation analysis, public transport balance analysis
Overview and methodological articles	6 %	

Source: own processing

In the following table (tab. 5) is summarized list of used research methods. It is visible for the first sight that in the selected articles is predominant quantitative research which used statistic analysis of secondary or primary data. When assessing qualitative research, it can be stated that some articles were focused on analysis of interviews done mainly with the employees of the transport companies.

Table 5. Used research methods overview

Research methods	Share of articles in %
Quantitative research (statistic analysis of secondary, primary sources)	70 %
Qualitative research (interview)	15 %
Overview	6 %
Case studies	9 %

Source: own processing

3.2 Analysis of tools/methods for efficiency/performance evaluation

In the following table (tab. 6) is introduced the overview of analytical tools that were mentioned in analyzed articles and that were used for data processing and further evaluation of efficiency and performance of public passenger transport.

Table 6. Analytical tools used for data processing

Analytical tools	Share of articles in %
DEA (Data Envelopment Analysis)	35 %
Tobit regression analysis, regresssion analysis, correlation analysis	22 %
AHP – criteria matrix model	14 %
Reports, indicators overviews	13 %
Multimodal graph – network morfology, network analysis	12 %
SFA (Stochastic Frontier Analysis)	4 %

Source: own processing

• **DEA – Data Envelopment Analysis**

The most often used method in analyzed articles was DEA - Data Envelopment Analysis (incidence 35 %).

Data Envelopment Analysis (DEA) represents specialized model tool for efficiency evaluation of decision-making units. The input and output weights are unknown in the model. The input-oriented model assumes that output is constant and that inputs have to be adjusted to maximize technical efficiency. The DEA method represents application of linear programming to analyzed data with the intention to create a production frontier against which the efficiency of each observed country or firm is measured. Based on the analyzed data, the DEA creates an efficiency frontier that is reached by the most efficient firm in the observed sample and against which the level of inefficiency of the others is measured (Tomeš, 2014).

According to the definition of efficiency, when the comparison of real performance with that which can be ideally reached using the same level of inputs consumption is done, then inputs and outputs are in fact compared.

In the analyzed articles using the DEA method can be met various approaches and combinations of input and output parameters.

Authors Costa et al. (2021) use in the analysis input parameters: operating costs, assets and liabilities and define as output parameters: revenues and earnings before interest and tax (EBITDA).

On the contrary, the authors Li et al. (2020) define as input parameters to the model: number of employees, number of vehicles and number of vehicle kilometers and define as output parameters: passenger kilometers and number of passengers. The authors of the article also define so-called exogenous variables that can affect efficiency. These variables are: population density of the researched area, GDP per inhabitant, presence of taxi service, presence of alternative public transport (e.g., urban railway), car ownership.

Analogous parameters are also used in another author's analysis (Saxena, 2019), which examines the efficiency of state-owned transport companies in India. The input parameters were defined as: fleet size, total number of employees and total costs. On the contrary, the output parameters were: passenger kilometers and total revenues.

The authors (Han et al., 2018) investigating the efficiency of bus transport in China assess separately the operational efficiency and separately the efficiency of the services provided. As part of operational efficiency, they then choose the input parameters: number of stations, PHM consumption and number of employees, and the output parameter here is the value of sales. For the efficiency of services, the input parameters were defined as: waiting time, travel time and accuracy rate, on the other hand, the output parameter was the number of passengers.

The study (Agarwal et al., 2010) evaluates the technical efficiency of the public transport sector in India and defines as input these parameters: fleet size, number of employees, PHM consumption and accident rate per kilometer, on the other hand, the output parameters were bus usage, passenger kilometers and load factor.

- **Tobit regression analysis, regression analysis, correlation analysis**

In the analyzed articles, methods of regression analysis and correlation analysis were noticed in connection with the DEA analysis.

For example the authors (Costa et al., 2021) analyse the impact of the model of urban rail networks ownership in Portugal and use the methodology in the calculation of DEA scores and the subsequent use of regression analysis to identify the main determinants.

Also the following article (Saxena, 2019) describing the efficiency of State Transport Corporations of India uses DEA technics and subsequently, a regression analysis tool.

For example, Tobit regression analysis, is used by the authors (Li et al., 2020) who construct a three-stage DEA model to eliminate the effects of exogenous environmental factors on the operation of public bus transport to obtain real efficiency results. The Tobit model was used for the subsequent analysis of the results.

Regression analysis is also used in the article (Boitani et al., 2010) investigating how ownership and institutional regime affects productivity in the public transport sector.

The article (Xylia & Silveira, 2017) working with the indicators so-called environmental performance indicators (proportions of renewable fuels, CO_2 emissions and energy efficiency) are analyzed based on interviews with employees, fuel preferences and best practices. Correlation analysis is then used to examine the dependence between population density or the volume of bus traffic and the achieved share of renewable resources.

- **AHP – criteria matrix model**

The authors (Lin et al., 2021) create an AHP public transport criteria matrix model, which includes the following criteria: basic level of infrastructure, level of public transport services, level of economic benefit and level of sustainable development.

Further article (Cyril et al., 2019) focusing on improving efficiency through optimization of available resources. These authors identify twelve decision variables within the AHP model. To these variables belong: controllable costs, uncontrollable costs, taxes, staff-to-bus ratio, safety, availability, regularity, load factor, fleet utilization, percentage of dead kilometers to effective kilometers, travel speed, percent of canceled kilometers, planned kilometers.

- **Reports, indicators overviews**

In the article (Alonso et al., 2017) focusing on the city public transport systems in Spain is efficiency analysis based on several indicators used to measuring supply, demand and efficiency.

The article (Hirschhorn et al., 2018) is focused on compilation of the overview of system metrics usable for public transport efficiency evaluation. To these metrics belong user satisfaction, cost recovery, modal split and level of system integration. The metrics were created based on a questionnaire survey with experts, which was evaluated using the Delphi method.

Also the article (Komorousová & Hinke, 2021), comparing the efficiency of the city public transpor in selected cities of the Czech Republic, works with the set of defined sub-indicators.

- **Multimodal graph – network morfology, network analysis**

In the article (Vrabková et al., 2016) is evaluated availability of public transport in municipalities in the Czech Republic by means of network analysis. The article examines the hypothesis that deconcentration practices of public administration lead to higher security costs and thus inefficiency.

The article (Wang et al., 2020) examines, how significantly contributes the morphology of China's public transport network to its performance. The research is carried out on the basis of the multimodal multigraph of the public transport.

The article (Cats, 2017) analyzes topological development of the multimodal railway network in Sweden. On the basis of this analysis are further analyzed changes in global efficiency and directness.

• **Method (SFA) Stochastic Frontier Analysis**

The article (Jarboui et al., 2013) measures the technical efficiency of public road transport providers in 18 countries and analyzes the extent to which various factors influence the level of technical efficiency. The research was conducted using the stochastic frontier analysis (SFA) method.

3.3 Limitations of research methods for efficiency evaluation

The limitation of the research methods is primarily the problematic availability of some sub-indicators, or possibly the inconsistency of the methodology for their quantification (e.g., number of passengers, passenger kilometres). In a number of cases, it is necessary to rely on a certain subjectivity of partial criteria (e.g., passenger satisfaction).

Limitation of the research is also given by the large number of criteria that can influence the efficiency of public transport. This also results in a non-uniform approach to the efficiency evaluation and in certain cases to impossibility of partial results comparison. It is also necessary to mention the considerable fragmentation in the understanding of the concept of efficiency. Some authors perceive it as efficiency in more technical form, others focus on efficiency with regard to the availability of public transport and the quality of services provided, other authors examine rather the efficiency of the transport network in relation to the level of infrastructure.

The number of criteria affecting the efficiency of public transport evaluation also leads to the necessity to use more complex statistical tools. Their construction can be quite complicated for some authors.

4 Discussions

Systematic literary research was conducted on the basis of Web of Science articles selection, where the main relevant issue was performance and efficiency in public passenger transport. With regard to the thematic focus of the articles, it is necessary to state that only 39 % of the articles from described selection were fully focused on more complex model of efficiency assessment, or more comprehensive structure of public transport efficiency indicators. Although the efficiency evaluation was a key concept in all selected articles, number of articles were limited only to evaluation of a certain partial factor or several partial factors influencing efficiency. Some articles were focused more on technical parameters and analyzed, for example, the performance of transport networks, their morphology and typology. Therefore, it can be concluded that compiling comprehensive model for efficiency evaluation can be quite complicated considering the large number of criteria that affect the efficiency of public transport.

With regard to the used research methods, it is possible to state that most of the articles used quantitative research and analyzed secondary or primary data.

When focusing on analytical tools used for the efficiency of public transport evaluation, it is necessary to write that large number of the articles was based on the DEA model – Data Envelopment Analysis. In the framework of this model, input and output criteria, or limiting variables, are proposed. In the model, efficiency is determined based on the linear programming task. On the basis of the comparison of individual articles, it was found that

the selection of input and output criteria is comparable for some models, but for some models it shows significant differences. The articles also used significantly often regression and correlation analysis tools. These tools were mostly used by the authors in connection with the DEA model (e.g., Costa et al., 2021, Lia et al, 2020, Saxena, 2020). Some authors used the AHP criteria matrix model to organize an overview of criteria for efficiency evaluation (Lin et al., 2021 or Cyril et al, 2019). Other authors limited themselves to a kind of overview or a set of metrics (e.g., Alonso et al., 2017, Hirschhorn et al., 2018, Komorousová & Hinke, 2021). In the articles focused on infrastructure performance, a network analysis tool was used (Vrabková et al., 2016), in some cases the authors worked with a multimodal graph and network topology (Wang et al., 2020). Only a small percentage of authors used the SFA (Stochastic Frontier Analysis) method (e.g., Jarboui et al., 2013).
