Foreign Investment, Legal Barriers, and Housing Policy: Transforming the Slovak Real Estate Market
Julius Golej and *Daniela* Špirkova 38

Employment Preferences of Slovak Economics Students in Domestic and Foreign Labour Markets
Tamara Hrušovská, *Tomáš* Koreň, *Matúš* Kubák , and *Jozef* Nemec 49

Analysis of the Cross-Border Mergers and Acquisitions Activity within EEA
Stela Kolesárová, *Alexandra* Chapčáková, *Juraj* Smatana, and *Vladislav* Stanko 55

Analysis of Performance Indicators of Small and Medium-sized Enterprises in the European Union
Jaroslav Korečko and *Ján* Vravec 64

Subsidies as a Tool for Increasing the Competitiveness of Slovak Farms
Ivana Kravčáková Vozárová, *Rastislav* Kotulič, and *Omar* Mohamad Abdulhafiz Mhemed 73

Underexplored Factors of Fiscal Outcomes in the Slovak Local Public Sector: Gender Standpoint
Lenka Maličká and *Dominika* Jusková 80

The Analysis of Key Indicators of Europe's Digital Transformation
Mária Matijová and *Beáta* Šofranková 89

Economic and Political Implications of Public Transport Discount Fares in Czechia
Alex Mican 100

Transforming Housing Through the Sharing Economy: The Case of Co-living as an example
Askar Mustafin, *Rastislav* Kotulič, *Galina* Tuguskina, *Natalia* Larionova, and *Valerii* Pureliani 111

Moldova at the Gates of the European Union
Andrea Nagy and *Zsuzsanna* Nagy 120

The Influence of Geopolitical Situations in the Middle East and Iran on the European Construction Sector in Cement and Concrete Production and Imports
Florian Struck and *Mária* Bohdalová 129

Progress in the Competitiveness of the Slovak Republic in the Context of Sustainability
Elena Širá 141

Digital Performance and Sustainable Competitiveness of EU-26 Countries in the Context of a Multidimensional Assessment
Beáta Šofranková, *Mária* Matijová, and *Elena* Širá 149

Flexibility in the Labor Market
Daniela Štellárová, *Marta* Urbaníková, *Tatiana* Bencová, and *Alexandra* Krivošíková 161

Trust in Economic Actors in the Czech Republic
Ilona Švihlíková and *Dana* Junková 168

2. Management

Challenges for Social Responsibility of Organizations in Market Economy Conditions
Nataliia Antoniuk, *Michaela* Harničárová, *Eva* Benková, and *Ľubica* Šarišská 176

An Analytical Perspective on Innovation in Recruitment & Selection of Employees
Jana Cocuľová, *Daniela* Bertová, and *Simona* Minďašová 187

Work Engagement Among Healthcare Professionals: A Comparative Analysis of Key Influencing Factors
Jana Cocuľová and *Veronika* Škerháková 193

Neuroscience in Leadership: An Integrative Framework for Optimizing Human Capital Performance
Kefah-Rakiaa Dabur and *Sławomir* Banaszak 199

Intercultural Communicative Competence Development in the Context of Managerial Foreign Language Education
Lucia Dančišinová 205

Sustainability of Social Service Provision in the Slovak Republic: An Innovative Example of Good Practice
Zuzana Draková 213

Organizational Resilience and Employee Well-being: An Evidence-Based Analysis of Workplace Interventions and Performance Outcomes
Nof Eilon 221

From Efficiency to Stability: Factors of Sustainable Strategic Management in Slovak Business
Patrik Fitala, *Renata* Skýpalová, *Zdeněk* Málek, *Peter* Šedík, *Adam* Klement, and *Milan Jan* Půček 228

Optimizing Managerial Decision-Making Processes in Complex Organizational Systems using Transformative Intelligence-Based Strategic Frameworks
Hila Fuchs 243

Transformative Intelligence in Decision-Making Processes and Policy Implementation Management: An Integrated Framework for Organizational Process Optimization in Complex Systems
Hila Fuchs 249

The Effect of Self-Efficacy and Perceived Career Threats on Attitude Towards Parental Leave
Petia Genkova and *Tim* Speckmann 256

Tax Management and the Effectiveness of Tax Crime Detection
Miroslav Gombár, *Nella* Svetozarovová, and *Anna* Burdová 265

The Fluid Reality Theory of Pygmalion Effect in Management: Integrating the Consciousness Equation and Oxytocin-Mediated Trust
Assaf Ichilov 276

Proactive Agility - Barriers and Capabilities of Companies: Evidence from Slovakia
Andrea Janáková Sujová and *Martin* Halász 282

Generational Perspectives on Employee Well-being
Terezie Krestová, *Nicola* Kubacká, and *Marcela* Papalová 290

Management of Intangible Assets: Aspects of Evaluation and Identification of Digital Assets of an Enterprise
Svitlana Labunska, *Volodymyr* Yermachenko, and *Mykola* Sidak 300

Level of Digitalization of Communication Media with the Public in Selected Cities
Marcel Lincényi, *František* Vojtech, and *Miriam* Slobodníková 314

Transformative Intelligence as a Core Competency for Educational System Management: Integrating Organizational, Technological, and Human Dimensions in 21st Century Leadership
Enrique Messer and *Reuven* Azulay 321

Workforce Stability in Healthcare: Key Predictors of Hospital Nurse Retention
Veronika Mozolová, *Magdaléna* Tupá, and *Monika* Gullerová 327

Strategic Measures to Secure Financing for Schools and Educational Facilities during the Energy Crisis: The Case of the Slovak Republic
Ľubomír Nebeský and *Jana* Barjaková 338

The Impact of Working From Home on the Motivation of Technical and Economic Workers in the Nový Jičín District: Barriers, Motivation and Impacts on Work-life Balance
Lech Nierostek, *Petra* Horváthová, *Tereza* Harabišová, and *Thi* Phuong Thao Diep 349

Deciphering Small Business Performance through Entrepreneurial Resilience: Empirical Findings from Sub-Saharan Africa
Timilehin Olasoji Olubiyi 358

Sports Management in the Dimensions of Managerial Functions
Iveta Petríková Rosinová and *Jana* Korcová 371

Microcredentials and Their Potential for Lifelong Learning and Human Resource Management
Simona Polonyová 380

Do Social Issues Matter? A Survey on Socially Responsible Behaviour of Businesses in the Czech and Slovak Republics
Renata Skýpalová, *Mária* Urbánová, and *Martin* Šikýř 387

Transformation of Traditional Approaches and Practices in Human Resource Management
Nella Svetozarovová, *Anna* Burdová, *Martin* Frohmann, and *Abdalah Yousef Mohamed* Gajem 399

A Theoretical Analysis of Work Environment Factors in Relation to Healthcare Worker Engagement
Veronika Škerháková, *Soňa* Kuchárová, and *Denis* Tirpák 406

Conceptualizing Employee Engagement in Slovak Healthcare: A Basis for Empirical Research
Denis Tirpák, *Veronika* Škerháková, and *Michaela* Harničárová 414

How Artificial Intelligence is Changing the Future of Human Resource Management and the Labour Market
Ľuba Tomčíková, *Daniela* Bertová, and *Jana* Cocuľová 422

Growth and Survival Strategies of Small and Medium-sized Enterprises in Slovakia
František Vráb and *Milan* Fiľa 430

Benefits of Using Key Performance Indicators in Management Process in Industrial Enterprises
Tsanka Zlateva-Petkova 438

Why And How Should Business Models in Industrial Organizations Be Transformed?
Tsanka Zlateva-Petkova 449

3. Business and Marketing

A Gender Perspective on Selected Neuromarketing Attributes to Enhance Sales
Zuzana Birknerova and *Lucia* Zbihlejova 460

Revealing the Neuromarketing Potential of NLP Subconscious Mechanisms in Entrepreneurial Practice
Zuzana Birknerová and *Eva* Benková 468

Advertising Literacy and Implicit Reactions to Brand Benefits:
A Case Study of Research on Implicit Reactions as a Complement to Verbal Feedback
Tamás Darázs 476

The Importance of E-Commerce in Global Enterprises
Juraj Fabus, *Miriam* Garbarova, *Petra* Holla Bachanova, and *Piotr* Gorzelanczyk 487

Visual and Psychographic Features of Advertising Creatives as Predictors of User Attention
on the Meta Platform
Igor Fedorko 495

Emotional Factors as Determinants of Purchasing Decision-Making in E-Commerce
Richard Fedorko, *Barbora* Talašová, *Lenka* Kráľová, and *Štefan* Kráľ 504

The Marketing Power of Customer Reviews in Hospitality Industry
Lujza Gunišová and *Peter* Štarchoň 513

The Impact of Unexpected Changes on the Determinants of Family Business in the Slovak Republic
Martin Halász, *Andrea* Janáková Sujová, and *Mariana* Sedliačiková 519

Analytical View of Online Consumer Behavior in Influencer Marketing within a Post-Pandemic
Market Environment
Jakub Horváth, *Igor* Fedorko, and *Mária* Jusková 529

Verbal Communicative Strategies in Intercultural Business Communication: a Theoretical Perspective
Irina Kozárová 536

An Analytical Examination of Consumer Purchasing Behaviour in the Context
of E-Commerce Sustainability
Lenka Kráľová, *Štefan* Kráľ, *Richard* Fedorko, and *Bianka* Herichová 543

The Use of Neuromarketing Tools in Evaluating the Effectiveness of Advertisements
in E-commerce Environments
Veronika Loumová, *Mária* Tomášová, and *Radovan* Bačík 550

The Effect of Omnichannel Logistics Service Quality on Customer Loyalty
M.A.R.D. Manatunga, *T.S.L.W.* Gunawardana, *D.M.T.* Madushanka, and *S.A.M.H.* Sudasinghe 559

Global Challenges and Digital Solutions: Communicating with Green Consumers in the Digital Era
Renáta Miklenčičová and *Michal* Kubovics 569

Analysis of Brand Awareness Level and Its Relationship with the Determinants of Brand Equity
Mária Oleárová and *Radovan* Bačík 577

Compulsive Buying in the Context of Socio-Demographic Characteristics
Ivana Ondrijová and *Róbert* Štefko 587

Marketing Tools for Increasing the Export Potential of Agricultural Enterprises
Nataliia Parkhomenko and *Lucia* Vilcekova 595

Gender Perspective on Perception of Healthy Food Advertisement by Entrepreneurs
Dagmara Ratnayake Kaščáková 605

Marketing Research in the Age of Industry 5.0: Insights from a Bibliometric Analysis
Martin Rigelský 614

The Impact of Loyalty Programs on Consumer Behavior: A Multivariate Analysis from Croatia
Marko Šostar, *Sapthasree Bharathanveettil* Thamban, and *Ante* Jozić 624

Neuromarketing as a Tool for Optimizing Multimedia Communication in the Tourism Sector
Róbert Štefko, *Nella* Svetozarovová, *Ľudovít* Nastišin, and *Marianna* Vrábová 645

Neuromarketing Insights into Visual Attention and Perception of Real vs. AI-Generated Images
Anna Tomková and *Dávid* Miško 654

Social Marketing and its Importance in Times of Global Instability and Uncertainty
Lukas Vartiak, *Iveta* Ubreziova, and *Miroslav* Skoda 665

Silence or Music? Consumer Preferences during Grocery Shopping and Their Implications for Marketing Practice
Peter Vaško, *Jakub* Berčík, *Elena* Horská, and *Patrik* Jurčišin 673

4. Finance

Beyond Linear Models: A Polynomial-Russell Interaction Framework for Predicting Stock Market Sensitivity to Financial Reporting Delays
Avraham Bookra and *Ariel* Fuchs 680

Analyzing the Accounting of Heritage Assets in the Public Sector: A Review of Research Trends
Daniela Feschiyan and *Radka* Andasarova 688

AI-driven Selection of Criteria for Measuring the Financial Performance of Enterprises
Jarmila Horváthová, *Martina* Mokrišová, and *Polina* Orikhan 696

Consequences of the Underestimated Role of Branches on the Effectiveness of the Greek Banks
Pantelis F. Kyrmizoglou 705

Fundamental Analysis and Optimal Portfolio of Companies Operating in the Semiconductor Sector
Magdaléna Musilová, *Ľudomír* Šlahor, and *Monika* Zatrochová 710

Financial-Economic Analysis in Smart Economy
Marek Nagy and *Katarina* Valaskova 720

The Impact of the Recognition of Deferred Tax Assets and Liabilities on the Usefulness of Financial Information
Nikolay Oresharov 735

The Role of Artificial Intelligence in Enhancing Financial Accounting Systems: An Applied Study on Startups
Nazahan Qahatan Sarhan 744

Analyzing Market Efficiency in the Israeli Stock Market
Kfir Saroussi 754

Examining the Impact of Financial Situation on Tax Discipline and Tax Evasion
René Vagaský and *Miroslav* Gombár 761

Analytical View of the Performance Limits of Small and Medium-Sized Enterprises in Slovakia
Ján Vravec and *Jaroslav* Korečko 774

5. Regional Development Management

Smart City Governance – a Cross-Regional Evolution Analysis of Patterns and Convergence Dynamics
Nir Abudraham, *Hujerat* Eslam, and *Alexander* Hait 783

Pre-pandemic Challenges and Socio-economic Disparities in the Prešov Region
Jaroslav Gonos, *Katarína* Čulková, *Jozef* Nemec, and *Anna* Tomková 790

The Role of the Solidarity Economy in Rural Areas
Katalin Lipták 805

Regional Impact of Public Support with a Special Regard to Investment Incentives in the Czech Republic
Martin Lukavec, *Hana* Černá Silovská, *Lucie* Jarešová, *Lucie* Burianová, and *Veronika* Špírková 812

Current State of Research on Administrative Capacity in Cohesion Policy: Topics and Unresolved Issues
Martina Michalíková and *Dagmar* Cagáňová 821

Development of Municipalities under the Influence of Fiscal Imbalance in Slovakia
Mária Murray Svidroňová and *Janka* Holíková 831

The Development of the Standard of Living in Slovakia
Mária Pleshanov 841

Analysis of Electromobility Development in the Slovak Republic from a Regional Perspective
Martin Rovňák, *Peter* Adamišin, *Matúš* Bakoň, *Simona* Minďašová, and *František* Chovanec 849

The Concepts of Regional Innovation Ecosystems
Silvia Ručinská and *Lenka* Jakubócová 857

6. Tourism, Hotel Management and Spa Industry

Educational Indicators as Determinants of Motivation for Participation in Tourism: An Analysis of Selected European Union Countries
Tomáš Bačinský 867

Investigating Generation Z's Preferences in Sustainable Tourism in Slovakia
Janka Beresecká and *Martina* Hudecová 876

Case Study of Marketing Tools and Strategies in DMOs in Slovakia: Current Status and Practice
Hana Bieliková, *Viktória* Bíziková, and *Norbert* Beták 883

Efforts to Implement Environmental Principles in Tourism Enterprises in Slovakia
Tünde Dzurov Vargová, *Daniela* Matušíková, and *Ivana* Šaffová 892

Marketing Strategies for the Valorisation of Cultural Heritage in Slovakia
Jaroslava Gburová, *Michal* Lukáč, *Martin* Halmo, and *Gabriela* Pajtinková Bartáková 901

Possibilities and Limitations of Innovative Marketing Communication in the Context of Slovak Towns and Municipalities
Denisa Jánošová and *Alexandra* Ďurovová 908

A Comparison of Hilton Hotel Reviews on Booking and Google in the V4 Countries
Stela Kolesárová and *Kristína* Šambronská 916

Differences in the Perception of Sustainable Tourism from the Perspective of Generations X, Y and Z
Erika Kormaníková, *Anna* Šenková, and *Gabriela* Strachanová 926

Financial Performance and Resilience of Slovak Spa Companies: A Comparative Analysis Before, During, and After the COVID-19 Pandemic
Martina Košíková, *Petra* Vašaničová, *Sylvia* Jenčová, *Marta* Miškufová, and *Kateryna* Melnyk 936

Perceptions of City Image Among Millennials: The Case of Prague, Vienna, and Budapest
Ivica Linderová, *Petr* Scholz, and *Hana* Kotoučková 947

Ensuring Digital Accessibility Under the European Accessibility Act: Legal Obligations for E-Commerce Platforms and Travel Agencies
Hana Magurová and *Eva* Tinaková 955

Digital Technology Preferences in Transport Services
Daniela Matušíková, *Tünde* Dzurov Vargová, and *Ivana* Šaffová 965

Travel Behavior Across Generations: Evidence from Slovak Women
Kateryna Melnyk, *Petra* Vašaničová, *Martina* Košíková, *Sylvia* Jenčová, and *Marta* Miškufová 975

Regeneration through SMART Tourism in Central European Countries
Ludmila Novacká and *Matěj* Pejsar 982

Cultural Tourism in the Perspective of Wellness:
Towards a Model of Smart Wellness Destination Cultural Driven
Tonino Pencarelli and *Mauro* Dini 993

Environmental Management and Eco-labeling:
Perceptions of Managers and Owners in the Lodging Industry
Petr Scholz and *Ivica* Linderová 1005

Preface

Global instability and uncertainty - economic, political, social, technological, and several other areas - deeply affect individuals, businesses, and public institutions. Unpredictable developments complicate decision-making processes and demand new approaches grounded in flexibility, resilience, and innovation. Searching for solutions in such conditions is not a passive endeavour but an active, strategic, and creative process that seeks to anticipate risks, adapt to change, and identify sustainable pathways forward. Global instability manifests itself through market volatility, trade tensions, geopolitical conflicts, shifting labour markets, and the growing complexity of decision-making processes. In such an environment, organisations, institutions, and individuals are confronted with new challenges, risks, and opportunities that require innovative, flexible, and knowledge-based approaches.

The present volume of conference proceedings is published on the occasion of the international scientific conference Economics, Management & Business 2025 - Searching for Solutions in Times of Global Instability and Uncertainty, which responds directly to these contemporary developments. The conference was organised on the occasion of the 21st anniversary of the establishment of the Faculty of Management and Business at the University of Prešov, which has more than two decades of experience in creating platforms for international scientific exchange. Throughout this period, the faculty has achieved significant results in education and research, strengthening its position among leading social science institutions in Slovakia. Its scientific activities are supported by specialised research laboratories, including laboratories focused on neuromarketing, neuro–human resources management, and related fields, and numerous national and international research projects, contributing to the advancement of modern management and business knowledge.

In recognition of its scientific output and research quality, the faculty has received the status of Excellent Research Workplace annually over the past four years and has repeatedly ranked among the top three institutions in the social sciences in Slovakia.

The thematic focus of the conference reflects pressing contemporary challenges. The primary ambition of the conference is to contribute to the development of theoretical knowledge as well as experience-based insights in modern economics, management, and business practice. It aims to foster meaningful interaction between academics and practitioners and to encourage the creation and strengthening of international research partnerships. The conference brought together participants from universities and institutions in more than twenty countries across four continents, underlining its truly global character.

We believe that the contributions published in this proceedings volume will offer valuable perspectives, stimulate further research, and support informed decision-making in times of global uncertainty. We hope that readers will find the insights presented here both inspiring and practically relevant.

Prof. Ing. Dr. Róbert Štefko, Ph.D.

Dean
Chairman of International Scientific Committee

1. Economics

Innovation Economics in Healthcare: How the Dental Implant Industry Navigated Global Market Disruptions and Created New Business Models (1980-2025)

***Umar* Dacca**[1,*]**, *Slawomir* Banaszak**[2]**, and *Ariel* Fuchs**[1]

[2] Uniwersytet im. Adama Mickiewicza, Faculty of Education, Poznan, Poland

Abstract

Research Background: Healthcare technology markets occupy a unique position in the global economy, combining innovation dynamics of technology sectors with the stability demands of essential services. Understanding how healthcare industries navigate disruption while maintaining innovation trajectories offers critical insights for business strategy and economic policy in times of global instability.
Purpose of the Article: This paper examines the transformation of the dental implant industry from a niche medical technology into a $6.2 billion global market, analyzing how key players developed resilient business models capable of weathering multiple economic crises while expanding accessibility across diverse markets from 1980-2025.
Methods: Using longitudinal analysis combining patent data, market statistics, industry archives, and stakeholder interviews spanning 45 years, this study traces industry evolution through multiple economic disruptions including the 1980s recession, 2008 financial crisis, and COVID-19 pandemic. We employ theoretical frameworks from innovation economics and organizational adaptation to understand strategic responses to uncertainty.
Findings and Added Value: Analysis reveals three distinct adaptation strategies that enabled consistent growth despite economic crises: (1) Scientific legitimacy leveraging - converting clinical research into market credibility and regulatory approval; (2) Ecosystem orchestration - building integrated networks of manufacturers, practitioners, and payment systems; (3) Market democratization through technology - using digital innovation to reduce costs and expand accessibility while maintaining premium positioning. The industry achieved a 17,600% ROI over 40 years while expanding accessibility from 1% to 35% of the population.
The study provides evidence-based frameworks for healthcare technology commercialization that demonstrate how breakthrough healthcare technologies can achieve sustainable commercial success while contributing to broader objectives of healthcare improvement and accessibility enhancement. These strategic frameworks offer actionable insights for managers, policymakers, and entrepreneurs navigating similar challenges in contemporary healthcare innovation.

Keywords: Healthcare innovation, Business model adaptation, Medical technology commercialization, Crisis management, Global market strategy

JEL classification: A10; J01; J11

1. Introduction

Healthcare technology markets occupy a unique position in the global economy, combining the innovation dynamics of technology sectors with the stability demands of essential services (Arrow, 1963; Newhouse, 1992). Unlike purely discretionary consumer technologies, medical devices address fundamental human needs that persist regardless of economic conditions, yet their adoption patterns reflect complex interactions between clinical efficacy, regulatory approval, professional acceptance,

* Corresponding author: docdoc10@live.com

and economic accessibility (Gelijns & Rosenberg, 1994). In an era of unprecedented global instability, understanding how industries navigate disruption while maintaining innovation trajectories offers critical insights for business strategy and economic policy.

The medical device industry is subject to many of the same economic forces that affect all highly innovative industries, with device producers needing to make reasonable profits while remaining vigilant of competitive strategies and technological advances (Institute of Medicine, 1991). However, the industry faces unique challenges due to what has been termed "polyintervention" - the complex web of public policies that wrap around virtually every stage of the innovative process to accomplish various public goals (Foote, 1986).

The dental implant industry provides an ideal lens for examining these dynamics because it straddles the boundary between essential healthcare and elective enhancement, serving both medical necessity and lifestyle aspiration. This dual nature has created distinctive market opportunities and challenges, requiring companies to develop sophisticated strategies for addressing diverse customer segments, payment models, and cultural contexts while maintaining scientific credibility and regulatory compliance.

The transformation from scientific discovery to global market leadership represents a comprehensive case study in healthcare technology commercialization. The industry's evolution from Per-Ingvar Brånemark's accidental discovery of osseointegration in 1952 to a $6.2 billion global market demonstrates how breakthrough medical innovations can achieve sustained commercial success through strategic adaptation to multiple economic crises.

Business model innovation has emerged as a critical capability for healthcare companies navigating uncertainty and managing the complex stakeholder relationships that characterize modern healthcare delivery (Javanmardi et al., 2024). The ability to adapt business models during crises - whether through creating new revenue streams, securing liquidity, or leveraging digital transformation - has proven essential for survival and growth in healthcare markets (Saebi et al., 2017).

The COVID-19 pandemic has provided a natural experiment in healthcare business model adaptation, forcing companies to rapidly reconfigure their operations while maintaining service delivery (Lyng et al., 2021). This context offers valuable insights into how healthcare organizations balance adaptation and innovation for resilience, particularly in technology-intensive sectors where both clinical efficacy and commercial viability must be maintained.

Contemporary research on healthcare innovation emphasizes the importance of dynamic capabilities and organizational agility in responding to environmental challenges (Biswas et al., 2021). The dental implant industry's experience across multiple economic cycles provides evidence for how sustained investment in scientific legitimacy, ecosystem development, and market democratization can create competitive advantages that persist through various forms of market disruption.

This study contributes to the broader literature on healthcare innovation economics by examining how a single industry successfully navigated 45 years of economic volatility while simultaneously advancing clinical outcomes and expanding market accessibility. The analysis reveals strategic patterns that may inform policy and practice in other healthcare technology sectors facing similar challenges.

2. Methods

2.1 Research Design

This study employs a longitudinal case study methodology to examine the evolution of the dental implant industry from 1980-2025. The research design integrates multiple data sources to construct a comprehensive analysis of business model adaptation strategies during periods of economic disruption, following established approaches in healthcare innovation research (Collins et al., 2016).

The methodology builds upon frameworks from innovation economics that examine how companies develop and maintain competitive advantages in technology-intensive industries characterized by high uncertainty and complex regulatory environments (Gelijns & Rosenberg, 1994). The approach recognizes that medical device innovation differs significantly from pharmaceutical innovation in terms of company size, R&D processes, and regulatory pathways (Roberts, 1988).

2.2 Data Collection

Primary Data Sources

- Industry archives and company documents spanning 1980-2025
- Patent databases and intellectual property records
- Regulatory filing documents and FDA approval records
- Financial reports and market analysis data
- Conference proceedings and industry publications

Stakeholder Interviews

- Semi-structured interviews with industry executives, clinical practitioners, and regulatory experts
- Historical interviews from industry publications and academic journals
- Documentary evidence from key innovators and company founders

Market Data

- Sales figures, market share data, and pricing evolution
- Adoption rates across different geographic markets and demographic segments
- Insurance coverage patterns and reimbursement policy changes

2.3 Analytical Framework

The analysis employs theoretical frameworks from several domains:

Innovation Economics: Drawing from literature on technological innovation patterns, market entry strategies, and competitive dynamics in healthcare technology markets (Arrow, 1963; Institute of Medicine, 1991).

Business Model Innovation: Utilizing frameworks for understanding how companies adapt their value propositions, revenue models, and stakeholder relationships during periods of uncertainty (Javanmardi et al., 2024; Saebi et al., 2017).

Crisis Management Theory: Applying concepts from organizational adaptation and resilience research to understand how healthcare companies maintain performance during economic disruptions (Lyng et al., 2021; Biswas et al., 2021).

2.4 Data Analysis

The analysis follows a structured approach to identify patterns across multiple economic cycles:

Temporal Analysis: Examining industry evolution across three distinct periods:

- Market creation phase (1980s-1990s)
- Industry consolidation phase (1990s-2010s)
- Digital transformation phase (2010s-present)

Cross-Case Comparison: Analyzing strategic responses of major industry players (Nobel Biocare, Straumann, Zimmer Biomet, emerging competitors) to identify common patterns and distinctive approaches.

Economic Impact Assessment: Measuring industry performance metrics during specific crisis periods (1980s recession, 2008 financial crisis, COVID-19 pandemic) to understand resilience mechanisms.

2.5 Validation Approaches

Data Triangulation: Cross-referencing multiple data sources to verify key findings and ensure accuracy of historical claims.

Expert Review: Validating interpretations with industry experts and academic researchers familiar with medical device commercialization processes.

Archival Verification: Confirming historical claims through multiple independent sources and official records where available.

This methodological approach enables comprehensive analysis of how a healthcare technology industry developed sustainable competitive advantages while navigating multiple forms of economic

disruption over a 45-year period. The framework provides a foundation for understanding strategic patterns that may be applicable to other healthcare innovation contexts.

3. Results

3.1 Market Creation Through Scientific Innovation (1980s-1990s)

The commercialization of osseointegration technology illustrates how breakthrough scientific discoveries require sophisticated business strategies to achieve market success. Brånemark's approach prioritized scientific credibility over rapid market entry, investing 25 years in research before beginning clinical trials. This extended validation period served multiple strategic purposes that became evident in retrospect.

Scientific Legitimacy Foundation

The extensive clinical documentation created an intellectual property foundation extending beyond basic patents. By the time competitors entered the market, Brånemark's team had established scientific protocols, clinical guidelines, and treatment standards that became industry benchmarks. This scientific legitimacy proved crucial for long-term market acceptance, validating principles from healthcare innovation literature about the importance of clinical evidence in medical device adoption (Roberts, 1988).

Economic Returns from Scientific Patience

- Research investment (1952-1985): $2.3 million
- Annual revenue by 1985: $15 million
- ROI after 33 years: 2,100%
- Long-term ROI over 40 years: 17,600%

Professional Ecosystem Development

Initial professional resistance was overcome through systematic education and training programs. The number of trained practitioners grew from 12 dentists globally in 1982 to 12,400 active doctors by 1995. This ecosystem development created switching costs and network effects that provided sustainable competitive protection, demonstrating how healthcare technology adoption depends on professional acceptance and training infrastructure.

3.2 Competitive Strategy and Patent Navigation

The entry of competitors like Straumann and 3i illustrates how patent landscapes can create innovation incentives that ultimately benefit end users. Rather than merely circumventing existing patents, successful competitors developed genuinely superior technologies while establishing independent intellectual property protection.

Straumann's Surface Technology Innovation

- SLA surface development cost: $12 million (1987-1991)
- Clinical improvement: 40% faster healing times
- Revenue from SLA patents through 2005: $340 million
- Market share achieved by 2000: 23%

3i's External Hex Connection

- Development investment: $3.2 million over 18 months
- First year sales: $8.7 million
- North American market share by 1995: 35%

These examples demonstrate how competitive pressure drove continuous innovation while expanding overall market opportunity, supporting economic theories about competition-driven technological advancement in healthcare markets (Gelijns & Rosenberg, 1994).

3.3 Industry Consolidation and Global Expansion (1990s-2010s)

The consolidation around three major players—Straumann, Nobel Biocare, and Zimmer Biomet—reflected distinct strategic approaches to building sustainable competitive advantages in a rapidly expanding global market.

Strategic Acquisition Patterns (1995-2005):

- Nobel Biocare: 23 acquisitions, $340 million investment, 39% global market share
- Straumann: 11 acquisitions, $180 million investment, 24% global market share
- Combined global presence: 67 countries

Zimmer's Orthopedic Synergies:

Zimmer's background in orthopedic implants provided significant advantages in materials science, surgical instrumentation, and regulatory navigation. Their market entry strategy leveraged:

- 23% manufacturing cost savings through shared titanium technology
- 40% savings in surgical tool development
- Investment of $95 million (2003-2006) generating $127 million revenue by 2007

3.4 Digital Transformation and Market Democratization (2010s-Present)

The integration of digital technologies represents one of the most significant disruptions in the industry's history, fundamentally altering competitive dynamics, value chains, and customer relationships.

Digital Platform Development:

- NobelClinician software development: $45 million (2004-2009)
- User growth: 340 doctors (2009) to 8,700 doctors (2015)
- Software revenue by 2015: $89 million annually

Market Democratization Impact:

The entry of lower-cost competitors, particularly from Asia, fundamentally altered market dynamics:

- European average price (2010): $650 per implant
- Osstem competitive price: $180 per implant
- Market response: 35% price reduction from established players
- Result: 67% total market growth (2010-2015)

3.5 Crisis Response and Adaptation

The industry's response to the COVID-19 pandemic demonstrates organizational agility and innovation capacity developed over decades of crisis navigation.

COVID-19 Pandemic Response:

- Initial impact: 87-91% decrease in procedures (April-May 2020)
- Digital transformation acceleration: Complete digital consultation systems developed in 6 weeks
- Recovery timeline: Return to 95% of 2019 sales levels by Q4 2020
- Growth acceleration: 23% growth above 2019 levels in 2021

Same-Day Treatment Innovation:

- Technology adoption: 2% (2015) to 31% (2023) of procedures performed same-day
- Economic impact: 67% increase in clinic profit margins
- Patient satisfaction improvement: 94% vs. 78% for traditional treatment

3.6 Framework for Medical Technology Commercialization

Analysis reveals a four-stage commercialization model that characterizes successful healthcare technology development:

Stage 1: Scientific Legitimacy Establishment (Years 1-10) Foundation through rigorous clinical research, peer-reviewed publication, and professional validation creates sustainable competitive advantages persisting beyond patent expiration.

Stage 2: Professional Ecosystem Development (Years 5-15) Building comprehensive professional ecosystems encompassing education, training, support services, and relationship management creates switching costs and network effects.

Stage 3: Market Infrastructure Creation (Years 10-20) Development of supporting infrastructure including financing systems, insurance coverage, regulatory frameworks, and patient education programs accelerates market expansion.

Stage 4: Platform Evolution and Democratization (Years 15-25) Evolution toward platform business models integrating multiple stakeholders and value streams while enabling market democratization through cost reduction and accessibility improvement.

This framework demonstrates how healthcare technology companies can build sustainable competitive advantages while navigating multiple forms of economic disruption, supporting broader theories about innovation patterns in regulated industries (Javanmardi et al., 2024).

4. Discussion

4.1 Theoretical Contributions to Healthcare Innovation Economics

The dental implant industry's 45-year evolution provides compelling evidence for several key theoretical propositions about healthcare technology commercialization. The industry's success in building sustainable competitive advantages while navigating multiple economic crises demonstrates that healthcare markets exhibit unique characteristics that differentiate them from other technology sectors.

The concept of "scientific legitimacy leveraging" emerges as a distinctive healthcare innovation strategy. Unlike traditional technology markets where rapid market entry often provides first-mover advantages, healthcare technology success requires extensive clinical validation periods that create intellectual property foundations extending far beyond basic patents. This finding supports Arrow's (1963) observations about uncertainty in healthcare markets while extending understanding of how companies can transform uncertainty into competitive advantage.

The four-stage commercialization model identified in this study provides a framework for understanding how healthcare technologies evolve from scientific discoveries to global markets. This model addresses gaps in existing innovation literature that often assume linear relationships between R&D investment and commercial success (Gelijns & Rosenberg, 1994). The extended timeframes and complex stakeholder relationships characteristic of healthcare technology commercialization require fundamentally different strategic approaches than those successful in other technology sectors.

4.2 Business Model Innovation in Healthcare Technology

The study reveals sophisticated business model adaptation strategies that enabled sustained performance across multiple economic cycles. The identification of three core adaptation strategies - scientific legitimacy leveraging, ecosystem orchestration, and market democratization - provides evidence for dynamic capability development in healthcare technology companies.

The ecosystem orchestration strategy demonstrates how healthcare technology companies must navigate complex stakeholder relationships involving clinicians, patients, regulators, and payment systems. This finding aligns with recent research on business model innovation in healthcare that emphasizes the importance of stakeholder integration and value network development (Javanmardi, et al., 2024). The dental implant industry's success in building comprehensive professional ecosystems created switching costs and network effects that provided sustainable competitive protection.

Market democratization through technology represents a particularly significant finding. The industry's ability to simultaneously reduce costs and expand accessibility while maintaining premium positioning challenges traditional assumptions about healthcare technology pricing strategies. This pattern suggests that digital transformation can enable new forms of value creation that benefit both companies and patients, supporting theories about technology-enabled healthcare delivery innovation (Saebi et al., 2017).

4.3 Crisis Management and Organizational Resilience

The industry's performance during multiple economic crises provides insights into organizational resilience mechanisms in healthcare technology sectors. The COVID-19 pandemic response, in particular, demonstrates how companies with strong scientific foundations and professional ecosystems can rapidly adapt to external shocks while maintaining service delivery.

The acceleration of digital transformation during the pandemic illustrates how crisis conditions can catalyze innovation processes that might otherwise require years to implement. The development of complete digital consultation systems in six weeks, compared to planned five-year timelines, supports literature on crisis-driven innovation and organizational adaptability (Lyng et al., 2021).

The industry's ability to achieve record growth levels (23% above 2019) within one year of the pandemic's onset demonstrates the resilience value of diversified business models and strong professional relationships. This finding contributes to understanding of how healthcare organizations balance adaptation and innovation during periods of extreme uncertainty (Biswas et al., 2021).

4.4 Policy Implications and Market Development

The study's findings have significant implications for healthcare policy and market development strategies. The demonstration that extended scientific validation periods can create sustainable competitive advantages suggests that regulatory frameworks requiring rigorous clinical evidence may actually benefit long-term industry development rather than hindering innovation.

The success of market democratization strategies provides evidence that healthcare technology accessibility can be improved through business innovation rather than only regulatory intervention. The industry's expansion from 1% to 35% population accessibility demonstrates how market forces can drive healthcare improvement when appropriate incentive structures are in place.

The role of professional ecosystem development in market creation suggests that healthcare policy should consider education and training infrastructure as components of innovation policy. The industry's investment in professional education created network effects that accelerated adoption while ensuring appropriate clinical implementation.

4.5 Limitations and Future Research Directions

While this study provides comprehensive analysis of one healthcare technology sector, several limitations should be acknowledged. The dental implant industry's characteristics - elective procedures, direct payment models, and relatively straightforward technology - may limit generalizability to other healthcare technology sectors with different stakeholder structures and payment mechanisms.

Future Research Priorities

- **Cross-sectoral analysis:** Comparative studies examining whether the four-stage commercialization model applies to other healthcare technology sectors such as diagnostics, therapeutics, or digital health platforms.
- **Geographic variation:** Investigation of how cultural and regulatory differences across international markets affect healthcare technology adoption patterns and business model effectiveness.
- **Digital transformation impact:** Longitudinal analysis of how digital technologies continue to reshape healthcare technology business models and competitive dynamics.
- **Stakeholder ecosystem evolution:** Research on how changing healthcare delivery models (value-based care, direct-pay medicine, telehealth) affect healthcare technology commercialization strategies.

4.6 Practical Implications for Healthcare Innovation

The findings offer actionable insights for healthcare technology entrepreneurs, established companies, and investors. The importance of scientific legitimacy establishment suggests that companies should invest in rigorous clinical validation even when market pressures favor rapid commercialization. The long-term competitive advantages created through clinical evidence development justify extended development timelines and higher initial costs.

The ecosystem orchestration strategy provides guidance for companies seeking to build sustainable market positions. Investment in professional education, training programs, and support services creates switching costs and network effects that provide protection against competitive entry. These investments should be viewed as essential infrastructure rather than optional marketing activities.

The market democratization findings suggest that digital transformation can enable new forms of value creation that simultaneously reduce costs and expand accessibility. Companies should consider how digital technologies can be leveraged not only for operational efficiency but also for fundamental business model innovation that creates shared value for multiple stakeholders.

4.7 Contribution to Healthcare Economics Literature

This study contributes to healthcare economics literature by providing evidence for how healthcare technology industries can achieve sustainable commercial success while advancing clinical outcomes and expanding accessibility. The demonstration that market forces can drive both innovation and accessibility challenges perspectives that view these objectives as inherently conflicting.

The identification of specific strategic patterns that enable resilience during economic crises provides frameworks that may be applicable to other healthcare sectors facing similar challenges. The evidence that scientific legitimacy, ecosystem development, and market democratization can create sustainable competitive advantages offers strategic guidance for healthcare technology companies navigating uncertain market conditions.

The research demonstrates that healthcare technology commercialization follows distinctive patterns that differ from other technology sectors, contributing to understanding of how regulatory environments, professional stakeholder relationships, and clinical evidence requirements shape innovation trajectories in healthcare markets.

Conclusions

This comprehensive analysis of the dental implant industry's evolution from 1980-2025 provides evidence-based insights into how healthcare technology industries can achieve sustained commercial success while advancing clinical outcomes and expanding market accessibility. The transformation from a niche scientific discovery to a $6.2 billion global market demonstrates strategic patterns that offer valuable guidance for healthcare innovation policy and practice.

Key Strategic Contributions:

The identification of three core adaptation strategies - scientific legitimacy leveraging, ecosystem orchestration, and market democratization - provides a framework for understanding competitive advantage development in healthcare technology markets. These strategies enabled consistent industry growth despite multiple economic crises, achieving a 17,600% ROI over 40 years while expanding accessibility from 1% to 35% of the population.

The four-stage commercialization model revealed through this analysis offers practical guidance for healthcare technology development timelines and investment priorities. The model demonstrates how extended scientific validation periods (10+ years) can create sustainable competitive advantages that persist long after patent expiration, challenging conventional assumptions about first-mover advantages in technology markets.

Business Model Innovation Insights:

The study provides evidence that healthcare technology companies can simultaneously reduce costs and expand accessibility while maintaining premium positioning through digital transformation and strategic ecosystem development. The industry's response to multiple crises demonstrates how established professional relationships and scientific credibility create resilience mechanisms that enable rapid adaptation to external shocks.

The COVID-19 pandemic response illustrates how crisis conditions can accelerate innovation processes, with companies achieving digital transformations in weeks that were originally planned for years. This finding supports theories about crisis-driven innovation while providing practical examples of organizational agility in healthcare technology contexts.

Policy and Market Development Implications:

The research demonstrates that rigorous regulatory requirements for clinical evidence may actually benefit long-term industry development by creating differentiation opportunities and

sustainable competitive advantages. This finding has implications for healthcare policy debates about balancing innovation incentives with patient safety requirements.

The success of market democratization strategies provides evidence that healthcare technology accessibility can be improved through business innovation rather than only regulatory intervention. The industry's expansion demonstrates how market forces can drive healthcare improvement when appropriate incentive structures are in place.

Theoretical Contributions:

The study extends existing healthcare innovation theory by demonstrating how uncertainty in healthcare markets can be transformed into competitive advantage through strategic scientific validation and ecosystem development. The findings support Arrow's (1963) observations about healthcare market characteristics while providing evidence for specific strategic responses to market uncertainty.

The research contributes to business model innovation literature by identifying healthcare-specific adaptation patterns that differ from other technology sectors. The importance of professional stakeholder relationships and clinical evidence in healthcare technology adoption creates distinctive commercialization challenges that require specialized strategic approaches.

Practical Applications:

For healthcare technology entrepreneurs and companies, the research provides evidence that investment in scientific legitimacy and professional ecosystem development creates sustainable competitive advantages that justify extended development timelines and higher initial costs. The strategic frameworks identified offer guidance for navigating complex regulatory environments and professional stakeholder relationships.

For policymakers, the findings suggest that healthcare innovation policy should consider education and training infrastructure as components of innovation ecosystem development. The industry's success in building professional ecosystems created network effects that accelerated appropriate clinical adoption while maintaining patient safety standards.

Future Research Directions:

The study opens several avenues for future research, including cross-sectoral analysis of healthcare technology commercialization patterns, investigation of geographic and cultural variations in adoption patterns, and longitudinal analysis of digital transformation impacts on healthcare technology business models.

Final Implications:

Most significantly, the research demonstrates that healthcare technology industries can create shared value for multiple stakeholders - achieving commercial success while advancing clinical outcomes and expanding accessibility. This finding challenges perspectives that view these objectives as inherently conflicting and provides evidence for how market-based approaches can contribute to healthcare system improvement.

The dental implant industry's 45-year journey from scientific discovery to global market leadership illustrates the potential for healthcare innovation to create sustainable competitive advantages while serving broader social objectives. The strategic frameworks and lessons identified provide actionable guidance for navigating similar challenges in contemporary healthcare innovation contexts, contributing to both academic understanding and practical application of healthcare technology commercialization principles.

Factors Influencing the Internationalization of Businesses in the Construction Industry in Slovakia

Mariana **Dubravská**[1,*]

[1] University of Prešov in Prešov, Department of Economic and Economy, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Internationalization is a key process for companies, enabling them to expand their field of activity beyond the domestic market. This process is influenced by a number of factors, such as economic and political conditions, technological progress, availability of capital, and the ability of a company to adapt to foreign markets. Slovakia is a small, open economy with a high degree of involvement in international trade.
Purpose of the article: Proponed paper offers analysis of the factors influencing the internationalization of business in the construction industry in Slovakia.
Methods: The research part focuses on analyzing the current state of internationalization in a selected industry. It also includes an assessment of development trends in selected areas of internationalization of these companies. Based on the information obtained about the forms and reasons for foreign trade activities interdependencies within this ongoing process have been identified.
Findings & Value added: Based on the processing of available data and a survey conducted among construction companies operating in Slovakia, it can be concluded that the purpose of the article has been fulfilled. The paper identified and analyzed key factors influencing the internationalization activities of companies operating in the construction sector in Slovakia.

Keywords: Internationalization, Construction sector, Slovakia

JEL classification: F02, F06

1. Introduction

The tendency to build international relations and trade is as old as humanity itself. Therefore, it would not make sense to analyze the entire history of trade and economic relations in detail. In this chapter, we will focus on modern history and the development of international relations.

According to Jones (2005), the beginnings of modern internationalization date back to the 19th century, when we see the first formation of modern international trade relations, mainly in the context of colonization and industrialization. The colonial campaigns of European powers led to the creation of new trade routes and relations, mainly with Africa and Asia. The spread of industrial technologies also laid the foundation for the later development of international relations.

In the ever-changing conditions of the current century, globalization and the expansion of international business have become determining factors for companies seeking growth and success. Expansion into international markets requires a systematic and well-planned approach. Internationalization is not a one-time event, but a complex process consisting of several phases, from initial market research to full integration into foreign markets. Each phase has its own specifics, demands, and challenges that companies must face. Most companies go through various stages of internationalization (Buck, 2004).

1.1 Internationalization

Internationalization is the oldest trend in the global economy. It is defined as the process of removing barriers between countries and creating mutual relationships, one of its current manifestations being the increased mobility of production factors and manufacturing output in the global economy (Hečková, Chapčáková ,2021).

Internationalization is part of many theories of business and greatly influences the decision-making process regarding business activities. Thanks to internationalization, companies become international or even global, as they conduct business in different business environments and outside their home country.

Thompson (2021) views internationalization as the process of adapting a product, service, or operational offering for entry and growth in international markets. He sees globalization as a possible end goal, but internationalization is the process through which a company can get there. Internationalization requires a thorough understanding of cultural differences, traditions, and different market preferences.

This concept was also addressed by authors in the last century. Among the classic and recognized definitions is this one from the well-known British economist J. Dunning (1988): Internationalization refers to the process by which companies increase their involvement in international markets.

Internationalization offers companies the opportunity to strengthen their position, achieve organic growth, and better utilize their corporate capital. It is clear that internationalization can bring many benefits to companies, but here too, there are two sides to every coin: positive and negative. The positive and negative aspects of business internationalization according to Mura (2010) can be summarized in a comprehensive form, as shown in Table 1.

Table 1. Positives and negatives of business internationalization

Positives of business internationalization	Negatives of business internationalization
Deepening the international division of labor	Increased intensity of competition
Blurring of national borders	Higher losses in the event of business failure in foreign markets than in the domestic business environment
Removing barriers to trade	The demise of entities that failed to adapt
Better utilization of corporate resources	Higher investment requirements for internationalization compared to domestic business
Growth and profit potential of the company	
An opportunity to gain experience in international business	
The opportunity to diversify business risk	
An opportunity to gain know-how	
The chance to get new customers, new markets	

Source: Mura (2010)

1.2 Factors influencing the internationalization of business

The process of business internationalization is very fragile, unstable, and dynamic. It can be influenced by a number of factors, which can be divided into several criteria. Whether internal, external, push, pull, technological, or other factors, they all contribute to companies' decision-making and their internationalization strategy.

Internal factors can be defined as those directly related to the capabilities and characteristics of a given company. There are many internal variables that influence the international activities of companies. Wach (2014) states that internal internationalization factors are rooted in the view of resources and points to three basic groups of factors, such as internal resources, capabilities and competencies, and business knowledge and experience.

Zahra and George (2002) conducted research into the internal determinants of international business and presented a set of three factors with the greatest impact on internationalization at the company level based on a view of resources, namely:

- top management team, especially experience working abroad, the origin of the founders, foreign education, and their vision of the global development of the organization,
- internal resources, especially unique ones such as expenditure on research and development activities and the company's reputation
- company specifics such as size and age, location, legal form, testing business environment, financial strength, and pro-development orientation.

External business factors are those that a company cannot influence and that arise from external conditions. Taking into account the research of several authors, we can divide external factors into the following groups:

- Economic – economic factors that influence the internationalization of companies include two groups of variables – demand (exchange rate, external demand) and cost variables (prices, salaries or wages, interest rates).
- Demographic – these include, for example, the size or structure of the population, urbanization, education, and lifestyle. These factors influence the behavior and needs of end consumers, which is why they are also important for companies when considering entering a given foreign market.
- Political and legal – in particular, the stability of political and legal conditions is considered an important stimulus for internationalization. Great emphasis is also placed on the extent to which governments can control or restrict the actions of foreign investors, as well as attract or even discourage foreign-owned companies from entering a given market (Belniak, 2015).

The second division is the division of internationalization factors according to their motivational influence. Here we distinguish between push and pull factors that influence the internationalization process of companies and their corporate strategy. There are several driving forces that motivate companies to enter foreign markets. These forces can be divided into pull (attractive) and push (pressing) forces.

Pull forces are proactive forces that attract companies to foreign markets and international expansion. They are usually associated with the attractiveness or better conditions of foreign markets. Pull factors are generally perceived as positive or opportunistic drivers of internationalization. For example, a new international market may have an emerging middle class with increased purchasing power, which represents a potential opportunity for a company. Attractive factors generally include market size, economic and social conditions, and characteristics of the foreign market (Francis, 2024).

On the other hand, push factors are reactive forces that "push" a company towards foreign markets. These are often internal or domestic unfavorable conditions that motivate or force the company to expand. Push factors are often considered negative, but this may not always be the case. In general, they can include resources, management expertise, corporate culture, and environmental factors (Evans et al., 2008).

2. Methods

The material used in the preparation of the Paper and the fulfilment of its objectives consists of primary and secondary sources. The primary sources of information are information obtained through own research activities—questionnaire survey. The survey focused on owners, their representatives, or managers who have knowledge about how the company works. We summarize the research sample as:

a construction company based in Slovakia that has the scope, interconnectedness, or experience with the foreign market.

The aim of the questionnaire was to gain deeper insights into the factors influencing the internationalization of business in the construction industry, to identify barriers and motivations for companies entering foreign markets, and to verify the hypotheses formulated in the theoretical part of the thesis. Given the nature of our data and the need to identify possible monotonic relationships without having to meet strict assumptions about data distribution, Spearman's coefficient was the most appropriate choice. Spearman's correlation coefficient is a non-parametric statistical method used to measure the strength and direction of a monotonic relationship between two variables.

3. Results

The construction industry is characterized by its stable presence in the Slovak economy, has high potential for expansion into foreign markets, and is very sensitive to global economic factors. This makes it an interesting candidate for analysis of internationalization development and potential.

According to the SITA agency (2023), construction is a strong and irreplaceable segment of the economy, as well as a barometer of the functioning of the economy. The reputation of the Slovak construction industry has been very good for decades. Construction is irreplaceable for the state in fulfilling social, economic, and political tasks, i.e., when it comes to housing, civil, and engineering infrastructure. As reported by TASR (2018), construction is important for Slovakia because it is low in import demand and independent of the economic cycle, meaning that if a crisis or other financial problems arise in other parts of the economy, construction can significantly stabilize it. It further states that the construction industry brings the largest volume of subsidies from European Union (EU) funds and other funds to Slovakia.

The Slovak construction industry is primarily focused on the domestic market. Domestic production remains stable at around 90%. However, on a positive note, 2023 saw a higher increase in foreign construction contracts, up by 1.88%. This trend may indicate the expansion of Slovak construction companies abroad, which may be a response to economic conditions or new opportunities outside Slovakia (see Figure 2).

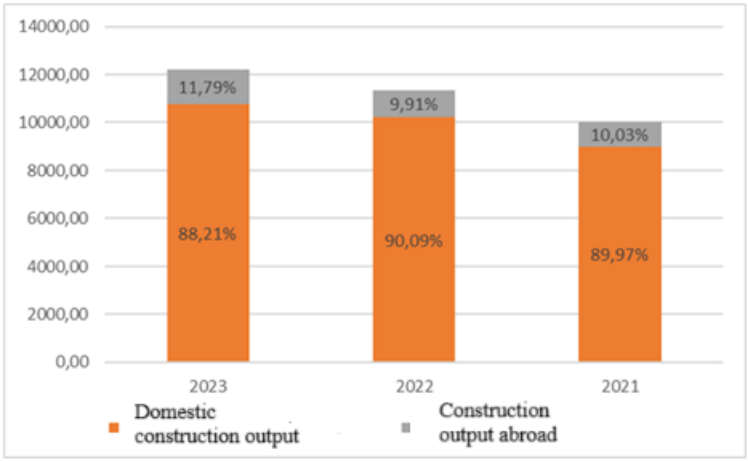

Figure 2. Share of domestic and foreign construction output for 2021–2023 (%)
Source: own processing according the Slovak Statistical Office (2025)

Figure 3 shows the volume of construction services exports in thousands of euros for the years 2019 to 2022. The blue curve shows the total volume of exports from Slovakia. The data is then supplemented by the five largest export partners for this period, which are the Czech Republic, Poland, Italy, Germany, and Austria, in that order. The years 2019 to 2021 are characterized by a significant decline in exports. The year 2021 is the most critical due to the pandemic. We see a similar trend in the Czech Republic (orange curve), which has long been the most important partner in the export of construction services. After a sharp decline in 2019–2021, exports recovered slightly in 2022.

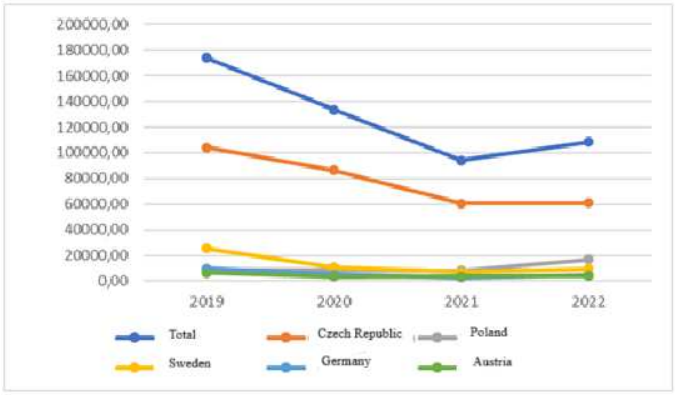

Figure 3. Exports of construction services for 2019–2022 (thousands of euros)
Source: own processing according the Slovak Statistical Office (2025)

The most significant growth was recorded in Poland (gray curve), where we see an increase in the volume of construction services exports. Other countries, such as Austria, Italy, and Germany, show relatively stable values, but at a lower level.

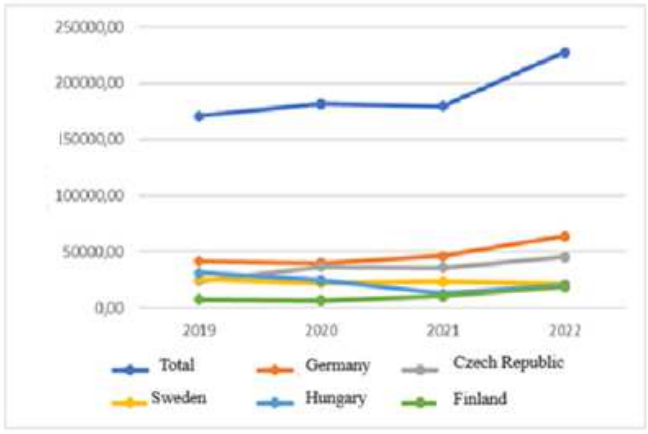

Figure 4. Imports of construction services for 2019–2022 (thousands of euros)
Source: own processing according the Slovak Statistical Office (2025)

Figure 4 shows the volume of imports of construction services in thousands of euros for the years 2019 to 2022. Here we see a slightly different trend than for exports. The total import volume was relatively stable for the first three years under review. The year 2021 saw only a slight decline. We also see a post-pandemic increase in this case, with a significant increase in 2022. The largest import partner is Germany. The Czech Republic is again close behind. Sweden (yellow curve) and Hungary (blue curve) show slight fluctuations in values without a significant trend. Finland (green curve) recorded growth in 2022, which may indicate new cooperation with the Slovak construction sector.

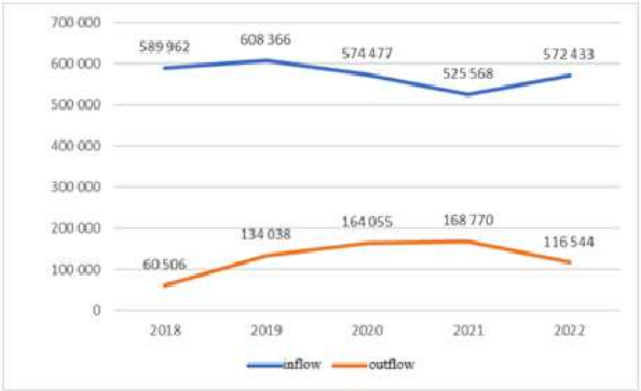

Figure 5. Inflow and outflow of FDI in construction for 2018–2022 (thousands of euros)
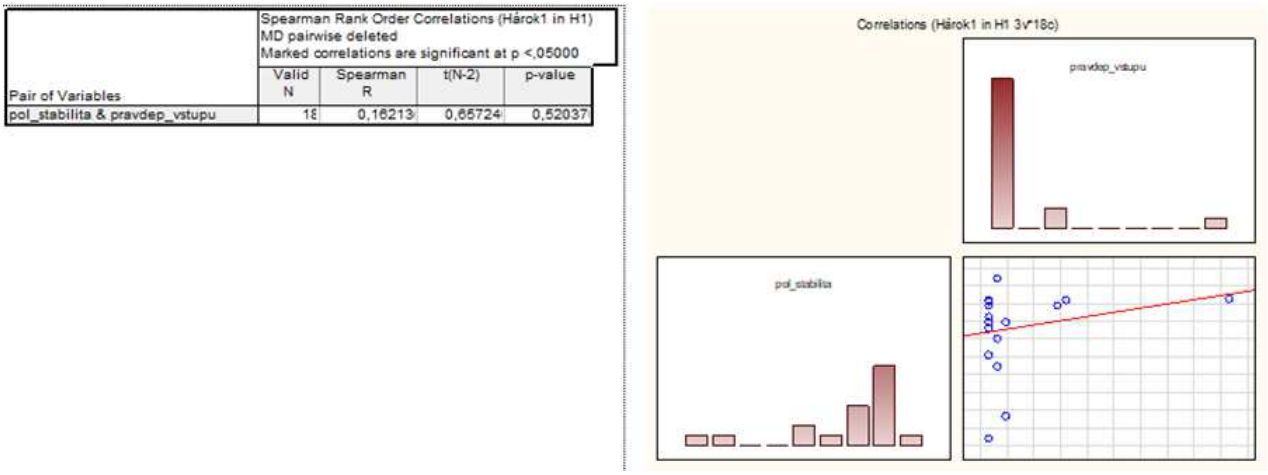
Source: own processing according the National Bank of Slovakia (2023)

Another way to analyze the internationalization of construction in Slovakia is through foreign direct investment. Figire 5 shows the inflow and outflow of FDI in the Slovak construction industry from 2018 to 2022 in thousands of euros. If we look at incoming FDI, we see a peak in 2019 of EUR 608,366 thousand. Conversely, the lowest value is understandably in 2021, at EUR 525,568 thousand. We can also see the post-pandemic economic recovery in this indicator, where in 2022 the volume rose to approximately the pre-pandemic level of EUR 572,433 thousand. FDI outflows showed a different trend during the years under review. For the period 2018–2021, we see an increase in outflows to other countries. The peak is reached in 2021, at EUR 168,770 thousand. After the pandemic in 2022, there was a significant decline in outflows of up to EUR 52,226 thousand. As far as FDI flows are concerned, the amount coming into Slovakia is much greater than the amount Slovakia sends out.

Another factor influencing the internationalization of the Slovak construction industry is definitely the movement of labor to and from the country. This indicator is important given the dependence of the construction industry on labor, its impact on the international competitiveness of Slovak companies, and it also serves as an indicator of market attractiveness. The largest number of Slovak construction workers leave to work in the Czech Republic, with as many as 5,711 doing so in 2019. 5,569 Slovaks left to work for foreign construction companies other than Czech ones. 160 people from abroad worked in Slovakia in the construction sector, of which 10 were migrant workers and 150 were refugees. We can see that a large number of Slovaks are leaving to work abroad, which significantly weakens the sector. On the contrary, there are far fewer foreign workers coming to Slovakia. As a result of these phenomena, the Slovak construction industry is struggling with a labor shortage.

As part of the statistical analysis, the questionnaire has been elaborated and sent to 208 companies operating in the construction industry in Slovakia, hypotheses were set and then subsequently verified. The aim of the questionnaire was to gain deeper insight into the factors influencing the internationalization of business in the construction industry, identify obstacles and motivations for companies entering foreign markets, and verify the hypotheses formulated in the theoretical part of the thesis. The set hypotheses discussed the statistically significant correlation between:

- political stability of countries and the likelihood of market entry



Spearman Rank Order Correlations (Hárok1 in H1)
MD pairwise deleted
Marked correlations are significant at p <,05000

Pair of Variables	Valid N	Spearman R	t(N-2)	p-value
pol_stabilita & pravdep_vstupu	18	0,16213	0,65724	0,52037

Figure 6. Evaluation of statistically significant relationship between political stability and market entry
Source: own processing

The study examined 18 countries identified on the basis of a questionnaire and their calculated probability of business entry. The resulting p-value is 0.52, which means that we cannot reject the null hypothesis and therefore there is no statistically significant correlation between the variables (Figure 6).

- financial strength of companies and their ability to expand

Pair of Variables	Valid N	Spearman R	t(N-2)	p-value
fin_sila_trzby & schopn_expandovat	50	0,952185	11,79129	0,000000

Spearman Rank Order Correlations (Hárok1 in H2)
MD pairwise deleted
Marked correlations are significant at p <,05000

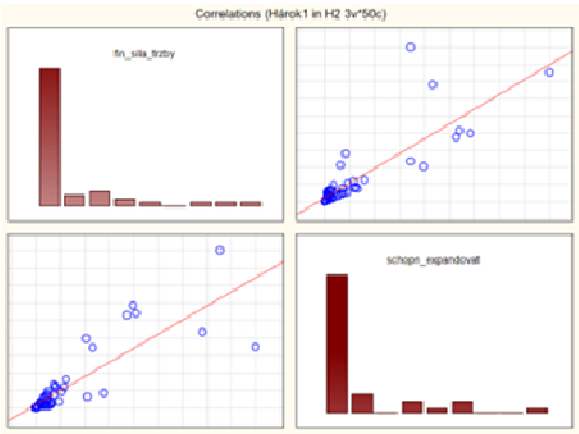


Figure 7. Evaluation of statistically significant relationship between financial strength and ability to expand
Source: own processing

The p-value is 0.00. We can therefore say that there is a significant correlation between the variables – the financial strength of the company and its ability to expand into international markets (Figure 7).

- development of construction material prices and willingness to expand abroad

Pair of Variables	Valid N	Spearman R	t(N-2)	p-value
zmena_trzieb_zahranicie & zmena_materialy	5	0,200000	0,288675	0,8000

Spearman Rank Order Correlations (Hárok1 in H
MD pairwise deleted
Marked correlations are significant at p <,05000

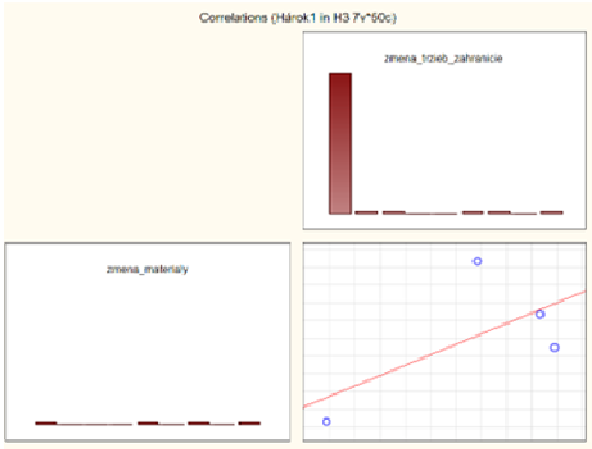

Figure 8. Evaluation of statistically significant relationship between material prices and expanding
Source: own processing

The resulting p-value is 0.8. Based on the test result with a p-value of 0.8, we do not reject the null hypothesis. No statistically significant correlation was found between the development of construction material prices and the willingness of construction companies to expand abroad (Figure 8).

4. Discussion

The development of the Slovak construction sector over the last two decades indicates its sensitivity to economic and political factors, with significant declines caused by the global financial crisis, shortfalls in EU funds, the COVID-19 pandemic, and geopolitical uncertainty resulting from the war in Ukraine. Despite these challenges, the sector is showing signs of recovery and expansion abroad. An analysis of the construction industry in the context of internationalization has shown that it is a stable and important sector of the Slovak economy with high potential for future expansion into foreign markets.

Conclusion

Internationalization currently affects an increasing number of companies from all sectors, including construction. Due to competitive pressure, domestic market saturation, or the need to expand their customer base, the number of companies with links to foreign markets is slowly increasing. Companies in the construction industry are seeking to expand beyond their borders through trade in construction materials, the implementation of projects abroad, investments, and various forms of cooperation with foreign partners. Even though the trend curve for the number of construction companies connected to foreign markets is slowly rising, there is still huge room for improvement in this sector.

Foreign Investment, Legal Barriers, and Housing Policy: Transforming the Slovak Real Estate Market

Julius **Golej**[1,*] **and** ***Daniela*** **Špirkova**[1]

[1] Slovak University of Technology in Bratislava, Institute of Management, Vazovova 5, 812 43 Bratislava, Slovakia

Abstract

Research background: Since the political and economic transition of the early 1990s, the Slovak real estate market has undergone significant transformation. Key drivers include foreign direct investment (FDI), changes in property-legal relations, and housing policy reforms. However, persistent issues such as an undersized rental housing sector and unresolved property rights continue to constrain market development.
Purpose of the article: This paper explores the evolution of the Slovak real estate market, focusing on the structural impacts of economic reforms, foreign investment, and policy decisions. Special attention is given to the consequences of housing privatization and the limited development of rental housing.
Methods: A longitudinal, mixed-methods approach was employed, combining macroeconomic and sectoral analyses. Data were drawn from Eurostat, the World Bank, and national sources. Key methods included trend analysis, regional comparisons within the Visegrad Four (V4), and assessments of policy impact and institutional change.
Findings & Value added: The research highlights how FDI, particularly in the automotive sector, has spurred housing demand in industrial regions while contributing to regional disparities. The rapid privatization of housing stock significantly reduced rental availability, constraining housing mobility and affordability. Unresolved property ownership, especially in state-owned assets, continues to impede investment and development. The study offers a comprehensive assessment of the Slovak real estate market's transformation, emphasizing the need for policy reform to enhance rental housing provision, legal clarity, and equitable market development. These findings provide valuable insights for policymakers, urban planners, and investors in post-transition economies.

Keywords: Slovakia, Housing market, Real estate market, Housing development, FDI

JEL classification: F23, R31, R38,

1. Introduction

Slovakia is one of the Visegrad Four (V4) countries (Table 1), whose other countries are the Czech Republic, Hungary and Poland. Over the last 30 years, they have significantly transformed their economies (Fig. 1), which has had significant implications for the real estate market.

Table 1. Geographic information on Visegrad countries (2022)

Country	Surface in kilometers square	Population
Czechia	88,891	10,670,000
Hungary	93,050	9,643,000
Poland	314,400	36,820,000
Slovakia	49,039	5,432,000
Total	**565,630**	**62,565,000**

* Corresponding author: julius.golej@stuba.sk

Figure 1. Gross domestic product (GDP) per capita (current million US$) - Slovak Republic, Czechia, Poland, Hungary
Source: World Bank (2025)

During the transition period, the Visegrad Four (V4) governments implemented key legislative reforms across several domains, including the Commercial Code, tax regulations, property registration, and territorial and municipal governance. These reforms significantly stimulated business activity in the real estate sector and enhanced the attractiveness of the V4 economies to foreign direct investment (FDI) (Fig. 2).

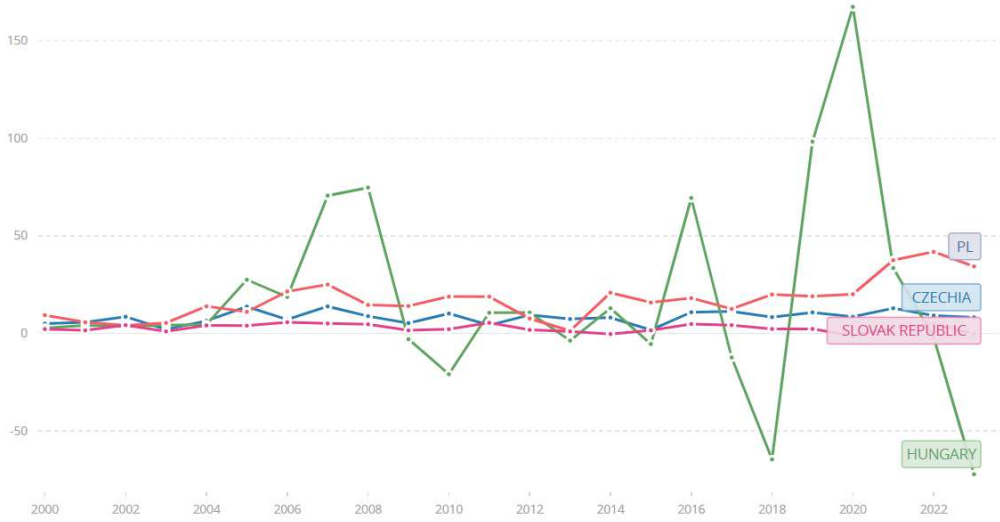

Figure 2. Foreign direct investment, net inflows (% of GDP) - Slovak Republic, Czechia, Poland, Hungary
Source: World Bank (2025)

A pivotal moment in Slovakia's investment landscape occurred in the year 2000, marking a breakthrough in its privatization strategy and its openness to foreign capital. By the end of that year, the stock of foreign direct investment had surged to approximately USD 6.49 billion (EUR 5.9 billion)—nearly double the amount recorded in 1999. This sharp increase underscores how institutional and legislative modernization catalyzed investor confidence, especially among international financial institutions and the banking sector. Slovakia's strategic geographic location, low labor costs, and highly skilled workforce were also decisive factors in attracting foreign capital.

FDI inflows carry considerable macroeconomic significance for host countries. In the short term, they provide essential external financing to offset current account deficits, contributing to currency stability or even appreciation (Altomonte & Resmini, 2001). Over the long term, FDI serves as a vital conduit for the diffusion of new technologies and managerial practices. The early post-transition years

saw the V4 countries enjoy heightened investor interest due to their comparatively higher levels of economic and political stability, accelerated reform efforts, superior economic performance, and advanced development relative to other post-socialist economies.

Scholarly interest in this transformation has coalesced around two principal research streams. One group of experts has concentrated on the role of FDI in economic development (e.g., Pavlínek, 2021; Kosztowniak, 2016; Táncošová, 2019; and Lizińska et al., 2022), while another has focused on the evolution of the real estate market and property price dynamics (Kishor, 2022; Yakubovsky & Zhuk, 2024; Jakimowicz & Kulesza, 2018; and Belej, M and Kulesza, 2020).

2. FDI as a driver of Housing Market development in Slovakia

One of the primary drivers of Slovakia's real estate market—both historically and today—has been substantial foreign investment in the automotive industry (Fig. 3), which remains one of the country's most vital economic sectors. As of 2023, the automotive industry contributes approximately 10.4% to Slovakia's GDP and directly employs around 255,000 individuals (Statistical Office of the Slovak Republic, 2024), underscoring its pivotal role in the national economy.

Slovakia has earned global recognition as one of the leading per capita producers of automobiles, with 198 vehicles manufactured per 1,000 inhabitants, making it the world leader in this metric. Current major foreign investors include Jaguar Land Rover and Volvo, each employing between 4,000 and 5,000 people as of 2023 (Statistical Office of the Slovak Republic, 2024). Moreover, the expansion of the automotive supply chain is expected to generate an additional 22,000 indirect jobs across subcontracting and service sectors.

Since 2000, Slovakia has attracted significant automotive investments from a range of global car manufacturers. These investments have not only advanced industrial development but also exerted a transformative influence on the real estate market, particularly through increased demand for housing in regions hosting automotive plants.

Figure 3. Selected foreign direct investment in Slovakia from 2000 to the present
Source: authors (2025)

The following summary outlines key foreign investments in Slovakia's automotive sector from 2000 to 2024. These data are based on public investment reports, corporate disclosures, and national statistical sources. Where precise figures were unavailable, estimates were derived using incremental trends and reported investment plans.

1. Volkswagen Slovakia

Since the 1990s, Volkswagen has served as a cornerstone of Slovakia's automotive industry. By 2023, its cumulative investments—including expansions, modernization, research and development, logistics, and infrastructure—had exceeded USD 6.05 billion (EUR 5.5 billion) (Statistical Office of the Slovak Republic, 2024).

2. PSA Peugeot Citroën (now Stellantis)

In 2003, PSA began construction of its plant in Trnava with an initial investment of approximately USD 770 million (EUR 700 million). Subsequent expansions and modernizations have raised the total investment to USD 1.32 billion (EUR 1.2 billion).

3. Kia Motors Slovakia

Kia launched its operations in Žilina in 2004, committing an initial USD 1.1 billion (EUR 1.0 billion). Over the years, further investments—particularly in production line expansions—have brought the cumulative total to approximately USD 2.2 billion (EUR 2.0 billion).

4. Jaguar Land Rover

In 2015, Jaguar Land Rover announced a major investment to establish a new manufacturing plant in Nitra. The initial commitment was around USD 1.54 billion (EUR 1.4 billion), with ongoing plans for further capital inflows.

5. Volvo

In 2022, Volvo declared its intention to build a new production facility near Košice, with an estimated initial investment of USD 1.32 billion (EUR 1.2 billion). The plant is expected to be fully operational by 2026.

Table 2 presents a summary of these cumulative investments. According to the authors' consolidated estimates, the total value of automotive industry investments in Slovakia from 2000 to 2024 is approximately USD 12.43 billion (EUR 11.3 billion). This figure encompasses not only factory construction and expansions but also modernization initiatives and research and development activities.

These substantial capital inflows have profoundly influenced Slovakia's economic landscape—driving employment, improving infrastructure, and accelerating growth in both industrial and real estate markets. As a result, Slovakia has emerged as one of Europe's leading automotive hubs.

Table 2. Total investment in the automotive industry from 2000 to the present

Automotive company	Amount of investment (in billions of USD)
Volkswagen Slovakia	6.05
PSA Peugeot Citroën (Stellantis)	1.32
Kia Motors Slovakia	2.2
Jaguar Land Rover	1.54
Volvo	1.32
Total	**12.43**

Source: authors, 2025

The automotive industry significantly influences Slovakia's real estate market through its substantial contributions to GDP, employment, and regional development. As illustrated in Table 2, major investments from companies such as Volkswagen, Kia, and Jaguar Land Rover have generated tens of thousands of direct and indirect jobs. These developments have, in turn, created considerable demand for both residential and commercial real estate—particularly in regions hosting automotive production facilities.

Regional Housing Demand

Cities like Bratislava, Trnava, Žilina, and Nitra have experienced a marked increase in housing demand, especially for rental properties. This surge is largely driven by the need to accommodate factory workers, subcontractors, and professional staff affiliated with automotive plants.

Corporate Housing Requirements

High-profile employers such as Jaguar Land Rover have also spurred demand for premium housing tailored to expatriate managers and specialized personnel. These professionals typically seek centrally located apartments equipped with parking, high-end amenities, and modern furnishings.

Infrastructure and Urban Development

The scale of automotive investments has necessitated substantial upgrades to infrastructure, including roads, public utilities, and transportation networks. These improvements not only support

industrial operations but also enhance the attractiveness of surrounding areas for further residential and commercial development.

In sum, the automotive industry's capital inflows serve as a powerful catalyst for real estate expansion in Slovakia, particularly in municipalities adjacent to major industrial zones. This sectoral synergy continues to play a pivotal role in shaping the spatial and economic landscape of the country (Statistical Office of the Slovak Republic, 2024).

3. Role of the Property Market

In advanced market economies, the real estate market plays a critical role in the allocation and redistribution of land resources, contributing significantly to overall economic prosperity. It serves as a mechanism for accessing real estate assets and offers a wide range of opportunities and choices regarding location, property type, lease conditions, and terms of occupancy across different economic sectors. Consequently, the real estate market is closely interconnected with manufacturing, construction, labor mobility, and broader national economic performance.

Given its deep integration with the functioning of the economy, any imbalance in the development of the real estate sector poses substantial risks to the financial system and economic stability. In mature economies, this systemic importance encourages institutional investors to commit capital to development projects. However, such a conducive economic and institutional environment is still underdeveloped in many post-transition countries, including Slovakia.

Following the political and economic transformation in Slovakia after 1990, significant reforms in property rights legislation were introduced to rectify injustices rooted in the 1948–1989 period. According to Machajdikova (2011), the process required legal mechanisms not only to address historical grievances but also to resolve inconsistencies between de jure and de facto ownership. To this end, the Act on the Regulation of Property Relations concerning Land and Other Agricultural Property was enacted. The Land Act of 1991 defined the categories of persons entitled to property restitution and established a timeframe for submitting supporting documentation. It also introduced the concept of land consolidation—encompassing the merging, subdivision, and legal regularization of land holdings—to reestablish coherent ownership rights.

Among the various components of the real estate market, housing is particularly significant, both economically and socially. It reflects broader patterns of social change and deprivation, and is inherently spatial in nature (Ivanicka, 2004). When making housing investment decisions, households consider multiple factors, including employment opportunities, household income, interest rates on housing loans, labor market status, and existing debt levels (Spirkova, 2018).

Since the early 2000s, the development of Slovakia’s housing market has been strongly influenced by sustained GDP growth, particularly in the industrial, construction, and agricultural sectors. In these areas, economic performance outpaced overall national output. Rising real wages, combined with low interest rates, also contributed to increased household consumption and greater accessibility to credit. These conditions supported both housing demand and broader patterns of consumption through debt-financed living standards.The transformation of Slovakia’s social and political system after 1990, coupled with housing policy reforms, facilitated the introduction of new housing finance mechanisms and significantly improved access to owner-occupied housing—primarily through property purchases and new construction. However, the extensive and often poorly managed privatization of the housing stock between 1992 and 2006 had profound consequences for the structure of the housing market, particularly the rental sector.

During this period, Slovakia experienced a sharp decline in the availability of municipal rental housing. According to historical records from the Ministry of Transport and Construction of the Slovak Republic (2024) and the Statistical Office of the Slovak Republic (2024), the share of municipally owned rental dwellings plummeted from 26.75% in 1991 to just 2.66% in 2006. In contrast, private homeownership surged from 51.13% to 92.21% over the same timeframe, highlighting the dramatic shift toward privatized housing. This data was compiled and analyzed by the authors using reported housing figures and cross-referenced with official annual reports on construction and privatization. Their calculations reflect the structural transformation of housing tenure in Slovakia resulting directly from privatization policies.

In total, approximately 340,000 flats were privatized between 1992 and 2006, leading to a marked reduction in the rental housing stock and reshaping the national housing market (Spirkova et al.,

2017). The long-term effects of this process continue to influence housing accessibility and mobility, particularly for lower-income and younger population groups.

The rental housing sector in the Slovak Republic is significantly undersized compared to the developed countries of Europe (as illustrated in Fig. 4). The shortage of rental housing was and is a consequence of

- the implementation of the inappropriate concept of privatisation of housing,
- problems of economic transformation (slow transformation of the housing sector) - rent deregulation was slow to avoid disturbing social peace,
- inappropriate incentive system for the development of rental housing (no incentives for private rental housing and an unsustainable subsidy system for social housing),
- the lack of tax breaks and favourable credit conditions, especially from commercial banks,
- the absence of non-profit developers on a larger scale, although the legislative preconditions for this are in place.

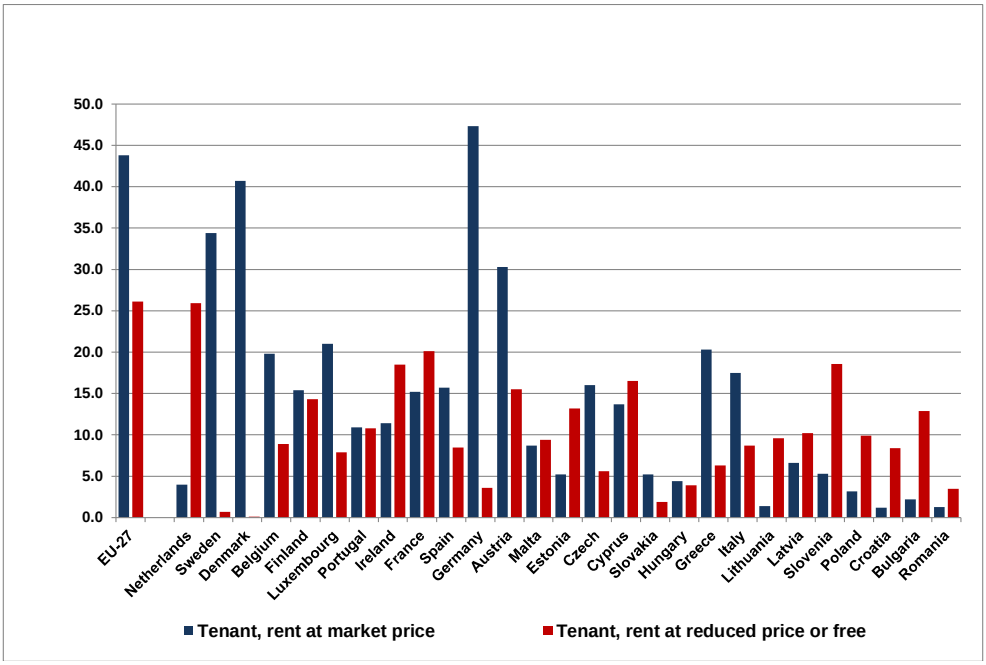

Figure 4. Population share by tenure status in %
Source: Eurostat (2023)

According to Eurostat (2023), rental housing accounts for only 5.2% of Slovakia's total housing stock, with reduced-price or subsidized rentals representing just 1.9%. These figures are markedly below the European Union average, underscoring a significant disparity in housing accessibility across the region. The acute shortage and increasing unaffordability of rental housing have made this issue a growing concern in public discourse and policy debates. Notably, the situation has shown little to no improvement in recent years, despite rising demand.

In addition to supply-side constraints, unresolved property relations pose a substantial barrier to real estate market development in Slovakia. There is currently no unified, comprehensive database covering property ownership across the entire country—only fragmented regional records exist. This lack of transparency primarily affects state-owned properties. In cases where buildings are state-owned but the underlying land has unresolved legal status, complications arise during restitution proceedings. Such legal ambiguities not only delay the settlement of property rights but also hinder investment and create barriers to financial compensation and further development.

4. Methodology and methods

This study employs a comprehensive research design grounded in extensive longitudinal analysis of the real estate market in Slovakia and the broader Visegrad Four (V4) region—comprising the Czech Republic, Poland, Hungary, and Slovakia. The scope spans the political and economic

transformation period from 1989 to the present day (2025). The methodology is structured to investigate both macroeconomic trends and microeconomic specifics that influence Slovakia's housing and real estate sectors, with an emphasis on the country's unique post-transition challenges and structural evolution.

The selected methodological approach is justified by its ability to integrate historical, political, and economic dimensions, thereby providing a holistic understanding of the real estate market's development. The longitudinal aspect enables a deep exploration of systemic transformations such as privatization, legislative reform, and the influx of foreign direct investment (FDI). It captures the critical interplay between policy decisions and market dynamics—an essential factor for contextualizing housing affordability, rental market undersizing, and unresolved property ownership issues.

Additionally, the use of macroeconomic indicators—such as GDP growth and FDI inflows—is complemented by qualitative assessments of legislative and institutional frameworks. The triangulation of multiple credible data sources enhances the robustness and credibility of the study's findings.

Data Sources and Description

This research draws on secondary data collected from reputable national and international institutions to ensure validity and comparability. The key data sources include:

Eurostat – Provides harmonized data on housing tenure, population statistics, and broader economic indicators across EU member states.

World Bank – Supplies longitudinal data on GDP per capita and foreign direct investment inflows.

OECD National Accounts – Offers standardized macroeconomic statistics consistent with international accounting frameworks.

Statistical Office of the Slovak Republic – Delivers region-specific data on housing stock, real estate prices, and demographic trends.

Ministry of Transport and Construction of the Slovak Republic – Contributes data on housing construction, rental housing availability, and legislative reforms.

The compiled dataset includes macro-level variables such as GDP per capita, FDI as a percentage of GDP, and housing construction rates, along with micro-level indicators like housing tenure structure and regional disparities in housing access.

Data Analysis Techniques

The study applies a combination of descriptive and inferential methods to analyze historical patterns, evaluate causal relationships, and forecast potential developments in the Slovak real estate market. The principal analytical techniques are as follows:

Trend Analysis – Examination of long-term data on GDP growth, FDI inflows, and housing construction to identify key inflection points and structural shifts.

Comparative Analysis – Benchmarking Slovakia's housing market against other V4 countries to assess relative performance and distinctive challenges.

Policy Impact Assessment – Evaluation of legislative reforms and their effects on housing access and market stability through case examples and conceptual frameworks.

Sector-Specific Analysis – Focused assessment of how Slovakia's automotive industry, as a major FDI recipient, affects housing demand in regional labor markets.

Quantitative Modeling – Use of basic statistical tools to explore relationships between variables such as household income, credit availability, and housing affordability.

This multi-pronged analytical strategy enables a nuanced interpretation of the real estate market's structural dynamics and policy-driven outcomes.

Discussion on Data and Analysis

The methodological robustness of this study lies in its interdisciplinary approach and reliance on diverse, high-quality data sources. By combining macroeconomic trends with sector-specific insights, the analysis captures the complex interdependencies that characterize Slovakia's real estate market. The study identifies persistent structural issues—including the undersupply of rental housing, fragmented property legislation, and FDI-driven regional disparities—that continue to shape housing

accessibility and affordability. Furthermore, the longitudinal and comparative dimensions of the analysis contextualize these findings within the broader trajectory of post-socialist transformation in the V4 region.

5. Results

Political reforms following the Velvet Revolution in 1989 necessitated wide-ranging adjustments to public administration structures and the implementation of new legislative frameworks. One of the key legal instruments introduced was the **Land Act of 1991**, which aimed to resolve longstanding property rights issues and address historical injustices rooted in the 1948–1989 period (Machajdikova et al., 2011; Ivanicka et al., 2004). Since the establishment of the independent Slovak Republic in 1993, significant changes have been enacted in the housing sector. As in other areas of the economy, housing policy transitioned from a centrally planned rationing system to a market-based framework, emphasizing private ownership and liberalization (Spirkova et al., 2017).

Improvements in the market environment became evident in the mid-2000s through increased housing construction. In 2005, **2.76 apartments per 1,000 inhabitants** were completed—a notable achievement driven by a surge in demand for owner-occupied housing. This high demand was fueled not only by strong economic growth and rising household incomes but also by evolving demographic patterns. The highest number of housing starts—20,592 units—was recorded in 2006, while 14,863 units were completed in 2005, marking the peak of new residential development.

The entry of foreign investors into Slovakia's financial market further catalyzed this growth, fostering innovation in housing finance. Commercial banks began prioritizing investment loans, project financing, and mortgage products aimed at owner-occupied housing construction. While this expanded homeownership, it also contributed to a decline in interest among developers for constructing rental housing, thereby exacerbating supply shortages in the rental sector.

As a result, while the market for luxury housing gradually became saturated, a severe shortage emerged in the segment serving middle-income households, young families, and new employees—particularly in regions experiencing industrial expansion. This imbalance drove subletting prices up by 10–30% in specific localities. For instance, executives from multinational firms like Jaguar Land Rover typically seek high-quality, centrally located, fully furnished apartments with secure parking—further straining supply in urban cores. The demand for two-room apartments is especially intense, often attracting 5 to 20 prospective tenants per unit, highlighting a critical mismatch between supply and demand.

The underdevelopment of the rental housing sector, both public and private, poses a significant barrier to labor mobility and may even contribute to elevated regional unemployment. The availability of rental units, particularly those with regulated rents or affordable market rates, remains acutely limited. According to the 2021 Census of Population, Houses, and Apartments, Slovakia had **2,235,586 dwellings**, of which **1,833,150 were occupied**, representing **82% occupancy**. However, the majority are owner-occupied, with rental options scarce and increasingly unaffordable.

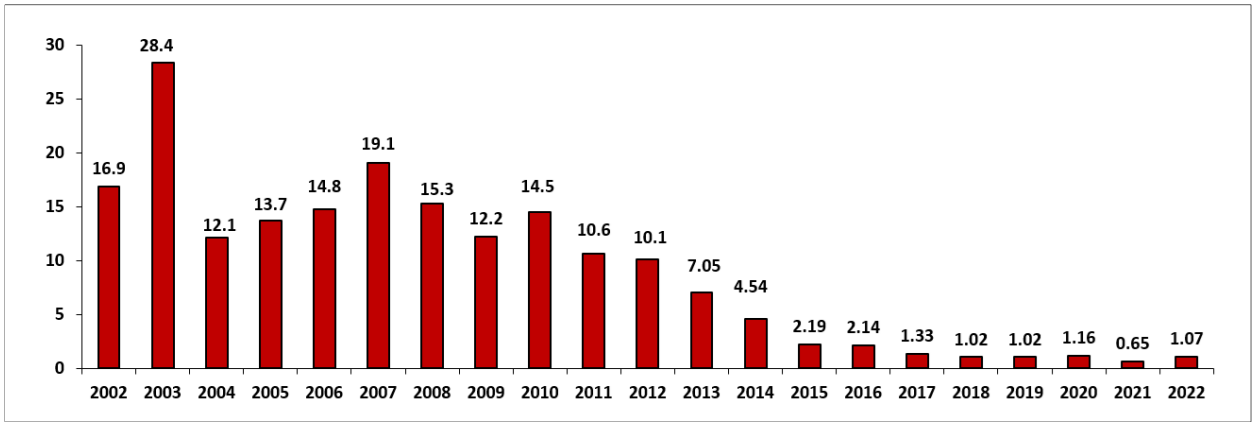

Figure 5. Number of completed dwellings in municipal ownership (rental housing) and their share (%) in the total number of completed dwellings between 2002 and 2022
Source: Ministry of Transport and Construction of the Slovak Republic (2024)

In recent years, rental housing has become a prominent and recurring issue in public discourse, primarily due to the declining affordability of homeownership for a growing segment of the population. One of the primary drivers of this trend is the rapid escalation of housing prices, which continues to outpace income growth and credit accessibility, further limiting options for low- and middle-income groups.

6. Discussion

A key institutional factor influencing the development and effective functioning of the real estate market is the presence of housing organizations. These entities form part of the broader institutional framework and play a crucial role in ensuring housing availability and affordability—particularly in countries where rental housing represents a substantial segment of the housing market. Notable examples include the Netherlands, Sweden, France, and Austria, where rental housing is supported by a robust tradition of non-profit housing organizations (Spirkova et al., 2018). In these countries, non-profit housing providers have historically emerged to address the housing needs of middle- and, more critically, lower-income populations. Their organizational forms are diverse and include limited liability companies, joint-stock corporations, housing cooperatives, foundations, and public benefit institutions. The development of this sector is typically driven by multi-level initiatives—from grassroots movements to external stakeholders and government policies.

Although Slovakia has established the **legal and regulatory framework** necessary for the formation of such organizations, the sector remains underdeveloped. There continues to be a notable **lack of initiative or interest** in founding non-profit housing bodies. This resistance may stem from uncertainty about the viability of these entities or concerns from private developers about potential competition. Nevertheless, such organizations could serve as **innovative development actors** - not only addressing the chronic shortage of rental housing for lower-income groups but also meeting the demand from higher-income demographics, such as expatriate managers employed by multinational firms operating in Slovakia.

Despite Slovakia's well-structured **subsidy mechanisms** to support rental housing construction, through instruments such as the State Housing Development Fund (ŠFRB) and direct grants from the Ministry of Transport and Construction, the emphasis on rental housing has diminished in recent years. Legislation such as **Act No. 443/2010 Coll.** (on subsidies for housing development and social housing) and the Ministry's 2019 decree outlining eligible subsidies and cost limits for rental housing construction remain underutilized.

International experience demonstrates the effectiveness of non-profit housing models in stabilizing rental markets and expanding affordable housing access. In Slovakia, a substantial portion of the population earns regular but insufficient income to meet the costs of high-quality housing. Moreover, **regional disparities in economic development** have led to significant differences in housing affordability across the country. These disparities disproportionately impact lower- and middle-income groups, exacerbating social inequality. The housing market, as currently structured, does not adequately meet the needs of all income groups, and is unlikely to do so in the foreseeable future. In this context, **non-profit housing organizations** could play a transformative role in mitigating housing inequality. They offer a viable solution for various vulnerable groups, including young people, senior citizens, and mobile workers, who require affordable rental options, whether on a temporary or longer-term basis.

Conclusion

This article highlights several critical implications for the real estate market in Slovakia, driven by historical, economic, and policy-related factors:

Impact of Housing Privatization. The large-scale privatization of housing stock (1992–2006) led to a significant reduction in rental housing availability, shifting the market toward owner-occupied properties. This change has restricted mobility and affordability, especially for lower-income and younger populations.

Undersized Rental Market. With only 5.2% of housing stock designated for rental purposes (Eurostat, 2023), Slovakia's rental market is among the smallest in Europe. The lack of rental housing limits workforce mobility, deters foreign investments requiring employee accommodations, and contributes to regional housing disparities.

Unresolved Property Relations. Unclear property ownership, especially in cases involving state-owned properties or land, hampers real estate development. These legal ambiguities often delay projects, discourage private investment, and create inefficiencies in property transactions.

Influence of Economic Growth and FDI. The influx of foreign direct investment, particularly in the automotive sector, has boosted housing demand in industrial hubs like Bratislava, Trnava, and Nitra. While this creates opportunities for real estate development, it has also driven up property prices, exacerbating affordability issues.

Regional Disparities. Economic and infrastructure development concentrated in specific regions has widened the gap between urban and rural areas. Property values and housing accessibility differ significantly, with urban centers experiencing overburdened markets and rural areas facing underutilization.

Need for Policy Reforms. The current housing policies lack adequate incentives for rental housing development and fail to address affordability challenges. Strengthening tax breaks, offering subsidies for non-profit developers, and fostering public-private partnerships could improve market balance.

Workforce Housing Challenges. The mismatch between housing availability and industrial growth has created a gap in mid-tier and rental housing for employees. This shortage risks limiting Slovakia's attractiveness as a destination for further FDI.

The research underscores the interconnectedness of economic policies, housing development, and property market dynamics in Slovakia. Addressing these challenges requires comprehensive reforms, targeted investments in the rental sector, and solutions to unresolved property rights to create a balanced and efficient real estate market.

Employment Preferences of Slovak Economics Students in Domestic and Foreign Labour Markets

***Tamara* Hrušovská**[1], ***Tomáš* Koreň**[2], ***Matúš* Kubák**[1,2,*], **and *Jozef* Nemec**[2]

[1] Technical University of Košice, Faculty of Economics, Department of Regional Sciences and Management, Nemcovej 32, 040 01, Košice, Slovakia
[2] University of Prešov in Prešov, Department of Economics and Economy, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Youth employment remains a key priority on the European Union's political agenda, particularly following the 2008 financial crisis. Despite numerous policy interventions, such as the European Youth Guarantee and vocational training subsidies, young adults continue to face complex challenges during the transition from education to employment. These challenges are formed not only by educational attainment but also by socioeconomic, regional, and cultural factors.
Purpose of the article: Paper map the employment preferences of Slovak university students with economic specialization, focusing on their inclination to work domestically or abroad. The study investigates how individual expectations, social background, and regional context influence decisions regarding employment location.
Methods: The study is based on a quantitative research design using an online questionnaire survey administered to 283 students aged 17–26 from four Slovak universities. The collected data were analyzed using descriptive statistics and binary logistic regression to assess the impact of selected factors on students' preferences for working abroad.
Findings & Value added: The analysis reveals that nearly 40% of respondents prefer employment abroad, driven primarily by perceived lack of career opportunities and professional development in Slovakia. Key predictors of foreign employment preference include skepticism about job availability in one's field, limited career growth, lack of valuable experience domestically, and willingness to relocate. Students from wealthier families are significantly less inclined to seek employment abroad. The study contributes to the understanding of push and pull factors that define employment decisions among young graduates.

Keywords: youth employment, labour migration, school-to-work transition

JEL classification: J61, R23

1. Introduction

The European Union's political agenda has consistently prioritized youth employment, and a focus significantly intensified following the financial crisis of 2008. The European Youth Guarantee stands as a core policy initiative addressing various facets of the "School to Work Transition" for young individuals aged 15–29. While the EU has implemented numerous educational measures and vocational training subsidies to facilitate labour market integration for graduates, these interventions represent only a fraction of the challenges young adults face in their job search (Simões et al., 2022). Education and professional skills are paramount, as increasing educational attainment generally correlates with a reduced likelihood of unemployment. However, an individual's career outlook is also formed by parental, social, and regional factors, often influenced by globalization and persistent structural disparities (Tosun, Arco-Tirado et al., 2019; Štefánik, 2018).

[*] Corresponding author: matus.kubak@unipo.sk, matus.kubak@tuke.sk

Despite policy efforts, youth employment in Europe remains uneven across regions, especially in Central and Eastern European countries, where socio-economic fragmentation continues to influence labour market outcomes (Tosun, Hörisch & Marques, 2019). Slovakia is emblematic of these challenges, facing persistent regional disparities and a notable outflow of young, skilled individuals who seek better prospects abroad (Kahanec & Mýtna Kureková, 2016; Richterová et al., 2014). Furthermore, the prevalence of dual labour markets in several European countries, including Slovakia, limits the availability of stable, high-quality entry-level jobs, discouraging long-term career planning among graduates (Cabrales, Dolado, & Mora, 2017). Such migration reflects not only perceived shortcomings in the domestic labour market, such as limited opportunities for advancement or innovation, but also a wider inconsstency between young people's expectations and the realities they encounter after graduation (Drbohlav & Hárs, 2018).

This study explores the factors influencing Slovak university students' employment preferences, particularly their inclination toward working abroad versus domestically. Building on previous theoretical work, we consider how individual expectations, social origin, and regional affiliation define their decisions. We argue that the School to Work Transition process cannot be fully understood without considering institutional, economic, and cultural factors that operate both nationally and internationally. Through a quantitative analysis of responses from 283 students in economic disciplines at four Slovak universities, this paper adds to the literature on youth labour mobility, perceived career security, and the drivers of cross-border employment intentions.

2. Data and Methods

The analytical component of this study is based on a quantitative research design utilizing an online questionnaire survey. The survey was disseminated to respondents via the Kahoot.it and Docs.google.com platforms. The target population comprised young individuals aged 17 to 26 currently enrolled in higher education institutions with an economic specialization in Slovakia. Specifically, participants were drawn from the Technical University of Košice, Matej Bel University in Banská Bystrica, Comenius University in Bratislava, and the University of Žilina.

A total of 283 relevant responses were collected through the questionnaire, with a relatively balanced gender distribution: 139 male respondents (49.12%) and 144 female respondents (50.88%). The survey instrument was divided into two main sections. The first section gathered socio-demographic information pertinent to the respondents' socioeconomic status, including gender, place of study, place of residence, social status, household income, household security, among others. The second section focused on young people's employment preferences. Data were collected on preferred employment location, desired professional field, perceived obstacles in the Slovak labour market, and perceived benefits of working in Slovakia, among other relevant aspects.

The data analysis proceeds in two main stages. Firstly we use descriptive statistical analysis to summarize general employment preferences. This includes preferences for employment location (city vs. village), preferences for working in Slovakia vs. Abroad. Further we apply binary logistic regression to model the likelihood of preferring employment abroad based on a set of explanatory variables. These include professional factors (perceived availability of jobs in one's field, opportunities for career growth), economic and infrastructural conditions (salary levels, quality of public services, willingness to relocate), and control variables (region of residence, family income).

3. Results

The initial descriptive analysis (3.1 Empirical Summary) focuses on preferred employment location, a key aspect given the globalized labour market. For very question, two hypothetical scenarios concerning employment were presented to respondents. Further, regression analysis (3.2 Regresion Analysis) identify the factors influencing respondents' decisions to work abroad.

3.1 Empirical Summary

First question investigates the job location preferences of students, specifically their willingness to accept higher-paying work in a capital city versus lower-paying work in a smaller village (Table 1).

Table 1. Scenario 1: Employment in Bratislava vs. Employment in a smaller town/village

You have just completed your university studies. You have two options:	Count	Percentage
Accept a job in Bratislava or near Bratislava	175	61.84%
Accept a job in a small town/village where the salary is 25% lower and 30 km from a larger city	100	35.34%
No response	8	2.83%
Total	283	100,00 %

Source: Own processing based on questionnaire data

Secondly, respondents were confronted by two choices, examining respondents' preferences between accepting a job in a regional city/its immediate vicinity and accepting a job in a small village/town with a 25% lower salary and a greater distance from a larger city.

Table 2. Scenario 2: Employment in a regional capital vs. employment in a smaller town/village

You have just completed your university studies. You have two options:	Count	Percentage
Accept a job in a regional city or its immediate surroundings (within 10 km)	254	89,75 %
Accept a job in a small town/village where the salary is 25% lower and 30 km from a larger city	28	9,89 %
No response	1	0,35 %
Total	283	100,00 %

Source: Own processing based on questionnaire data

In the second scenario, a substantial majority (89.75%) preferred employment in a regional capital or its immediate vicinity (within 10 km). Only approximately 10% were willing to accept lower-paid work further from a regional or larger city. This indicates that young people generally seek higher-paying jobs after graduation to secure their future and access a wider range of professional and private opportunities. The shift in percentages compared to the first question suggests a general preference for larger cities due to better career prospects, though a notable segment still prioritized staying in their home region over Bratislava, even at the cost of lower remuneration.

The third question, central to our analysis, explored the preference for working domestically or abroad. Respondents choices are in the Table 3.

Table 3. Scenario 3: Employment in Slovakia vs. employment abroad

You have just completed your university studies. You have two options:	Count	Percentage
Employment in Slovakia	172	60.78%
Employment abroad	111	39.22%
Total	283	100.00%

Source: Own processing based on questionnaire data

Nearly 40% of respondents expressed a preference for working abroad. This finding suggests a potential dissatisfaction with current working conditions or opportunities within Slovakia. It implies that foreign employment is highly attractive to a significant portion of the respondents, likely due to higher salaries or enhanced career advancement opportunities. Conversely, 60.78% preferred working domestically, possibly motivated by closer family ties, absence of language barriers, and a general sense of comfort within their home country.

The fourth question examined whether respondents preferred working in Slovakia or in a neighboring EU country (Austria, Czech Republic, Poland, Hungary). Respondents preferences are in the Table 4.

Table 4. Scenario 4: Employment in Slovakia vs. employment in neighboring country

Work in Slovakia or a neighboring EU country	Count	Percentage
Work at home (SK)	164	57,95%
Work in a neighboring country	119	42,05%
Total	283	100,00%

Source: Own processing based on questionnaire data

The distribution of responses shifted slightly, with the demand for foreign work increasing by almost 3%. Approximately 58% preferred working in Slovakia, while 42% opted for a neighboring EU state. This suggests that when considering international employment, respondents frequently favor countries geographically and culturally close to Slovakia, such as the Czech Republic or Austria, due to linguistic and cultural similarities, as well as proximity to family.

3.2 Regression Analysis

The primary objective of the regression analysis was to identify the factors influencing respondents' decisions to work abroad. We deploy binary logistic regression where each coefficient β indicates the strength and direction of the association between the respective independent variable and the likelihood of preferring employment abroad. Regression model has following specification:

$$\left(\frac{Pr\,(Employement\ abroad\,)}{1-Pr\,(Employement\ abroad)}\right) = \beta_0 + \beta_1 Work\ in\ the\ field_i + \beta_2 Career\ growth_i + \beta_3 Valuable\ work\ experience_i + \beta_4 Cost\ of\ living_i + \beta_5 Public\ services_i + \beta_6 Salaries_i + \beta_7 Relocation\ for\ work_i + \beta_8 Poor\ infrastructure_{\ i} + \beta_9 Region\ of\ residence_i + \beta_{10} Family\ income_i$$

where the log-odds of preferring employment abroad are expressed as a linear function of several explanatory variables. These include professional factors such as the opportunity to work in one's field, prospects for career growth, and gaining valuable work experience, as well as economic and infrastructural considerations like cost of living, quality of public services, salary levels, willingness to relocate for work, and perceptions of poor infrastructure. Additionally, the respondent's region of residence and family income are included as control variables. Regresson analysis results are in Table 5.

Table 5. Regression analysis

Variable	Group	B	S.E.	Wald	Sig.	Exp(B)

	€1501+	-1.825	0.7472	5.971	0.01452	0.162

Source: Own processing based on questionnaire data

Regression analysis reveals thay several factors significantly influence students' preferences for employment abroad. The analysis shows that students who do not believe they will find a job in their field of study in Slovakia are 3.38 times more likely to prefer working abroad compared to those who believe they will. Similarly, respondents who do not see suitable opportunities for career

growth in Slovakia are over four times more likely to choose employment abroad. The perception that valuable work experience cannot be gained in Slovakia also significantly increases the likelihood of seeking work abroad, raising the odds by almost 2.88 times. Another significant factor is willingness to relocate for work, students who do not consider relocation within Slovakia a barrier are 2.29 times more likely to prefer employment abroad. Moreover, those who do not consider poor infrastructure as a major barrier are 1.83 times more likely to seek work abroad. Regional differences were also significant, students from Eastern and Western Slovakia are more likely to prefer employment abroad compared to those from Central Slovakia. Finally, students from families with the highest income bracket (€1501+) are significantly less likely to prefer employment abroad, with odds reduced by 84% compared to those from the lowest income group. Regression analysis findings suggest that perceived limitations in the domestic labor market (lack of professional opportunities, career stagnation, and weak infrastructure) are key push factors in students' decisions to seek employment abroad.

4. Discussion

Study found that a significant portion of Slovak university students specializing in economics are inclined to seek employment abroad, driven largely by structural shortcomings within the domestic labour market. The logistic regression analysis confirms that perceptions of limited job availability, lack of career advancement opportunities, and insufficient prospects for gaining valuable work experience in Slovakia serve as strong push factors. These findings are consistent with existing research on youth employment in Europe, where the misalignment between graduate expectations and national labour market realities remains a recurring issue (Tosun et al., 2019; Simões et al., 2022).

An important contribution of this study is its identification of how regional and socioeconomic differences influence employment decisions. Students from Eastern and Western Slovakia showed a higher tendency to consider foreign employment than those from Central Slovakia, which likely reflects regional disparities in economic development and infrastructure. Additionally, the finding that students from higher-income families are less inclined to work abroad may relate to stronger social capital and better access to domestic opportunities. This supports theories suggesting that mobility is not solely a function of ambition but also of perceived necessity (Cabrales et al., 2017).

Furthermore, students expressed a clear preference for employment in larger urban areas over rural regions, accentuationg the importance of urban infrastructure, professional networks, and quality of life in location preferences. This urban bias mirrors extensive European patterns, where cities act as magnets for young talent but simultaneously contribute to regional imbalances.

Conclusion

The results of the study identify the urgency of addressing structural and regional inequalities within the Slovak labour market to improve graduate retention. Policies aimed at increasing the attractiveness of domestic employment opportunities should focus on expanding career development programs, enhancing regional infrastructure, and supporting innovation outside of major urban centers. In particular, targeted support for economically weaker regions may reduce the need for young talent to seek better conditions abroad.

If unaddressed, the current dynamics may reinforce existing trends of brain drain, especially among highly educated youth with strong foreign language skills and international aspirations. Given the cultural and geographic proximity of many EU labour markets, Slovakia remains vulnerable to continued outmigration unless systemic improvements are made. Strengthening links between higher education, regional development, and the labour market should be a core element of future policy strategies to retain qualified graduates and promote inclusive economic growth.

Abstract

Research background: Mergers and acquisitions are a common designation of transactions related to the purchase and sale of companies, parts of companies, assets, shares and business units. Creation of national or international companies linked to the capital brings benefits not only to the stakeholders but also, to a certain extent, to the whole organization and its further sustainability.
Purpose of the article: Since 1990s, the popularity of mergers and acquisitions (M&As) and cross-border M&As has greatly increased thanks to globalization and technological development. The purpose of the paper is to analyze the volume of the realized cross-border M&As within EEA in the monitored period.
Methods: Correspondence analysis was used to acquire the results and define the volume of the implemented cross-border M&As within EEA divided into five intervals.
Findings & Value added: The results of the analysis show that, among the purchasing companies, the lowest implemented M&A volumes were recorded in Malta, Cyprus, Poland and Greece, while the largest volumes in Germany and France. In the group of the purchased companies, the lowest volume of mergers and acquisitions was recorded in Malta and Slovenia, the highest in Luxembourg. These results indicate the necessity to examine and analyze the reasons for these outcomes in further, country-specific detail.

Keywords: Cross-border merger, Cross-border acquisition, EEA, Correspondence analysis

JEL classification: F15, F21, F23

1. Introduction

Cross-border mergers and acquisitions have become the dominant form of foreign direct investment in the world economy over the past three decades (Erel et al., 2022). Progressive globalization is an important factor in the growing importance of cross-border mergers and acquisitions, which can be perceived as one of the main forms of integration that enables companies to create synergies, gain economies of scale, reduce costs, increase market power, and create an overall competitive advantage (Bhagat et al., 2011; Hečková et al., 2016).

Various studies describe M&As transactions to describe the theoretical motives of cross-border M&As as follows: acquisition of production capacity, specific market experience of target enterprises, strategic motives of cross-border trading companies within the oligopoly, and the ability of some multinationals to better control or manage specific countries (Hyun and Kim, 2010). The following section will examine the theoretical framework of the issue at hand, which will serve as a base for the subsequent analysis of the cross-border M&A activity in European Economic Area, particularly during the period of 1998-2022, when M&As had undergone a turbulent, active era.

Raff et al. (2007) and Neary (2007) classify merger and acquisition motives into the following groups:

* Corresponding author: alexandra.chapcakova@unipo.sk

- companies with a high Tobin Q-index are those which have the best technology and seek opportunities to expand their share capital;
- efficiency gains increase as takeovers increase economies of scale or bring other synergies in the form of tax incentives;
- strategic increments increase when cross-border mergers and acquisitions change the structure of the market, the competitive position, and the level of profit by creating monopolies or oligopolies;
- building "empires" allows to diversify and hedge against shocks in the particular sector;
- managers may be motivated by managerial compensations or their own decisions.

Mergers and acquisitions are a common designation of transactions related to the purchase and sale of companies, parts of companies, assets, shares and business units. Creation of national or international companies linked to the capital brings benefits not only to the stakeholders but also, to a certain extent, to the whole organization and its further sustainability (Trąpczyński et al., 2018; Frankovský et al., 2019).

The four most commonly used indicators of acquisition performance are: (1) cumulative abnormal returns, (2) divestment data, (3) managers' assessments, and (4) expert informants' assessments (Schoenberg 2006).

The acquisition of companies by means of mergers and acquisitions is considered to be a dynamic process (Georgopoulos et al. 2008) and, at the same time, one of the most risky capital interconnection processes undertaken by companies (Boubakri et al., 2012; Alexandrou et al., 2014).

According to Sharma and Raat (2016), the motivation for mergers and acquisitions varies considerably, depending on the particular business, the industry, the current economic environment and other influencing factors. De Pamphilis (2015) states that the main advantage of cross-border mergers and acquisitions is the provision of foreign market access, while domestic mergers and acquisitions reduce the competitive pressure on the domestic market.

A favorable regulatory environment, a more stable political background in the host country, low foreign tax rates, cultural differences, geographical and country-level governance differences are considered important motives for cross-border M&As (Šoltés and Gavurová, 2014). Zhu et al. (2014) consider strategic market entry as the main motivation for cross-border mergers and acquisitions. Mergers and acquisitions are seen as a fast way to enter a new market in a new country and the authors state that the acquirer enters the market across borders by acquiring an already established trading company. In this way, the acquirer can use distribution channels, a proven brand name, a qualified workforce, management experience and local knowledge. Cross-border mergers and acquisitions give companies access to resources that may not be available in their domestic economy, thus enhancing their ability to be competitive (Rani et al., 2016).

Mergers and acquisitions can reduce operating and transaction costs, improve efficiency and improve resource dependency management. They are primarily driven by the interest of the trading company management itself (Guadalupe et al., 2012). The Central and Eastern European markets are becoming increasingly attractive to merger or acquisition connections as they offer high profit margins, low wages and cheap labor costs Eurostat (2016). In addition, there are specific and very favorable conditions for investment in the last countries to have joined the Union. Recent research by Chapčáková et al. (2022) demonstrates that the deepening of European integration, the expansion of the European Union, and the creation of the European Monetary Union (EMU) have significantly contributed to the increase in cross-border M&A activity within the European area. The introduction of the euro, liberalization of trade and investment regimes, and regulatory harmonization have created a more homogeneous business environment, facilitating capital reallocation through cross-border mergers and acquisitions.

2. Methodology and Structure of Used Data

The main aim of the paper is to analyze the volume of implemented cross-border mergers and acquisitions divided according to the European Union countries in the monitored period of 1998-2022. The analysis is divided into two parts. In the first part we monitor those Member States of the European Union, which initiated implementation of cross-border mergers and acquisitions most frequently, and the volume of their implementation. In the second part we analyze those Member

States of the European Union which were most often targeted by cross-border mergers and acquisitions, and in what volume they were carried out. We conducted the analysis for the aforementioned period of 1998-2022.

In both parts of the analysis, we focused on an identification of the countries where M&As were similar in their volumes. Correspondence analysis was used to acquire the results and define the volume of the implemented cross-border mergers and acquisitions in the individual Member States of the European Union divided into five intervals.

For the purposes of the analysis, a database containing records of cross-border mergers and acquisitions carried out in the European Economic Area (EEA) and in Turkey, the data of which were taken from the Zephyr database Bureau van Dijk (2023), was used. Our database includes data on mergers and acquisitions carried out from 16 source countries[1] to 25 target countries[2] in the selected production[3] and service[4]sectors. MS Excel and SPSS statistical software were used to process the analysis results.

3. Data Analysis and Results

The analysis focuses on the determination of the volume of cross-border mergers and acquisitions (hereinafter as M&A) by countries within EU during the period of 1998-2022. Figure 1 depicts the evolution of total volume of M&As during this period.

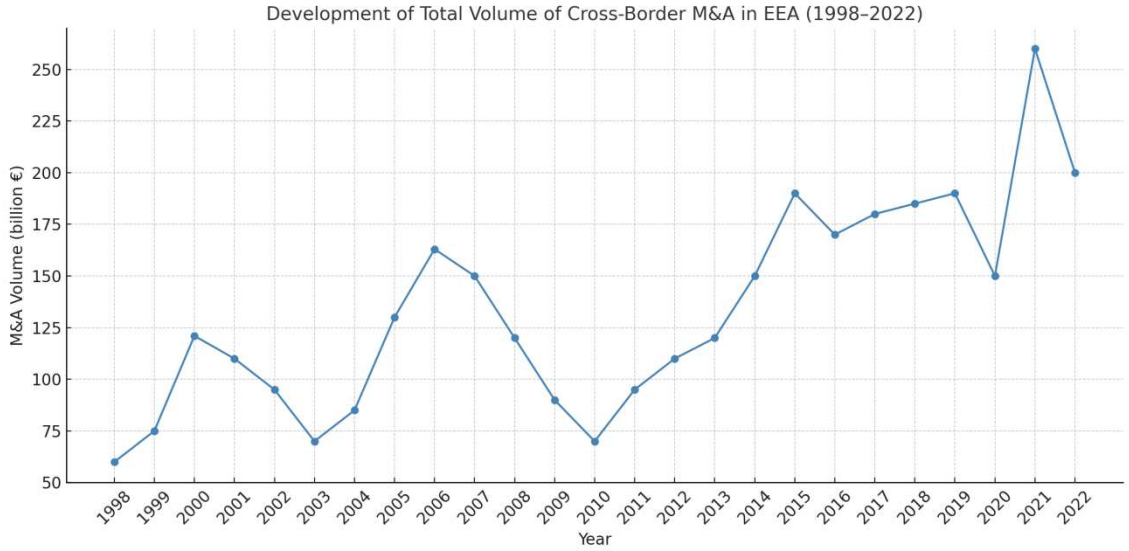

Figure 1. Development of Total Volume of Cross-Border M&A in EEA (1998–2022)
Source: own processing based on Zephyr and Orbit databases (Bureau van Dijk, 2023)

Our analysis is divided into two parts. Firstly, we are interested in the amount of cross-border M&As in the source countries, where the enterprises purchasing other enterprises are based. Secondly, we are interested in the countries, where the purchased enterprises are based. In both cases, we try to identify the countries in which cross-border M&As are similar in their volumes. We use correspondence analysis to reveal the relationship between the countries and the total summary of cross-border mergers and acquisitions during the mentioned period. Correspondence analysis is a

[1] Belgium, Republic of Cyprus, Denmark, Finland, France, Greece, Netherlands, Luxembourg, Republic of Malta, Federal Republic of Germany, Republic of Poland, Portuguese Republic, Republic of Austria, Spain, Italy, United Kingdom

[2] Belgium, Republic of Bulgaria, Republic of Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Greece, Netherlands, Republic of Lithuania, Republic of Latvia, Luxembourg, Hungary, Republic of Malta, Federal Republic of Germany, Portuguese Republic, Republic of Austria, Romania, Slovak Republic, Republic of Slovenia, Spain, Italy, Turkey, United Kingdom

[3] Food, Beverages, Tobacco, Textiles, Clothing, Leather, Chemicals, Rubber, Plastics, Non-Metallic Products, Metals and Metal Products, Machinery, Equipment, Furniture, Recycling, Gas, Water, Electricity, Construction

[4] Transportation, Hotels and Restaurants, Post and Telecommunications, Insurance, Banking

statistical technique that provides a graphical representation of cross-tabulations. It is an exploratory technique designed to analyze data in the pivot tables, while its aim is to reduce dimensionality. It provides a measure of correspondence between rows and columns of a pivot table, and allows studying the relationships between two categorical variables. Correspondence analysis is also useful in cases when the graphical output is clearer than the numeric outputs. Outputs of correspondence analysis are similar in its nature to results of a factor analysis. A correspondence analysis output is represented by a two-dimensional graph, a so-called correspondence map.

We note that evolution of the total volume of cross-border M&As hit its peaks and bottoms. Peaks were reached in the years of 2000, 2006, 2015 and 2021. This development was due to the results of the analyses reported in Bureau van Dijk's annual reports (2000, 2006) from 2000 to 2006 by a gradual deregulation of the market and a simultaneous increase in internet penetration within the area in question, causing the cross-border mergers and acquisitions between 2000 and 2006 record their highest value of the implemented volume in the sectors of Telecommunications, Media and IT. The $2.95 trillion M&A record of 2000 was surpassed in 2006, when 29,000 M&A amounting to $3.8 trillion were carried out worldwide, with an emphasis on EEA, representing a 10% increase over 2000. In the examined European area in 2000, 1,987 mergers and acquisitions worth $121 billion were carried out, and in 2006, 2,527 mergers and acquisitions worth $163 billion were implemented. In addition, in the period of 2000-2006, the stock market trend was increasing, thus significantly improving the financing of investments and, at the same time, achieving a relatively high profitability of trading companies. This was reflected in the increase in capital reallocation through mergers and acquisitions both worldwide and in the European area, with their peak in 2006. Contrarily, minimal values of the cross-border M&A amounts were attained in 2003 and 2010. At the beginning of 2003, the cross-border M&A activity decrease was linked to the “dot-com bubble” (internet stock bubble). The internet stock bubble is a term for a period during which the value of the so-called dot-com internet businesses (using the .com domain) rose sharply. After cooling, the value dropped sharply and many companies went bankrupt.

The latent sources of the financial crisis (Mikušová and Horváthová, 2012) had not yet been made explicit by 2007. The fall in share prices led to a decrease in the value of cross-border M&As transactions. Serious economic instability in 2009 (not only in the Eurozone countries) dampened the acquisition appetite of strategic investors. The global M&A activity fell by 22% to $2.3 trillion in 2009, compared to $2.94 trillion in 2008. The decline in cross-border M&As transactions was significantly affected by a reduction in national GDP of the individual countries, global financial instability, a decline in oil prices, and deterioration in export prospects. After 2015, the EEA M&A market experienced a period of stabilization and moderate growth, with annual volumes ranging from €160–190 billion. The covid-19 pandemic in 2020 led to a temporary decline of 15–20% in transaction value. However, 2021 saw a record surge in M&A activity, driven by low interest rates, accumulated investment capital, and increased activity in private equity and technology sectors. In 2022, the volume dropped by approximately 20–25% due to the impact of the war in Ukraine, inflation, and tightening financial conditions. The findings of Chapčáková et al. (2022) also provide detailed evidence on the direction and volume of cross-border M&A flows. For example, the United Kingdom, France, the Netherlands, and Germany were the most important source countries, with France recording the largest financial volume of outbound M&As (€80.7 billion). On the target side, France, Germany, and Spain attracted the highest volumes of inbound M&As, with France as a target country receiving €56.3 billion in cross-border transactions. These patterns underline the dominant role of large and developed economies in European M&A activity

3.1 Purchasing enterprises – M&As volumes

For purposes of this analysis, we scale the summary of cross-border M&A volumes into 5 intervals. Using binning, we define 5 intervals of cross-border M&A volumes with similar frequencies, which are:

1. (≤ €2,619,000),
2. (€2,620,000 – €8,975,000),
3. (€8,976,000 – €28,000,000),
4. (€28,001,000 – €130,000,000),
5. (€130,001,000 ≤).

Every interval contains about 1,160 observations.

An interesting fact about purchasing enterprises is that only the enterprises from the 16 EU countries are performing cross-border M&A. Table 1 contains details of correspondence analysis. A Chi-square test is designed to analyze categorical data. That means that the data has been counted and divided into categories. Pearson's chi-squared test is a statistical test applied to sets of categorical data to evaluate how likely it is that any observed difference between the sets arose by chance. Categorical data is statistical data consisting of categorical variables (a variable that can take on one of the limited possible values). Pearson's chi-square test p-value is 0.000 (column Sig.), thus we reject the null hypothesis of non-dependence of data and we suppose that there exists the dependence between the data – country of origin and cross-border M&A volume. The first dimension of the analysis captures 67.7% of inertia, and the second dimension captures 19.2% of inertia. Total inertia captured by correspondence analysis is 86.9% (column Proportion of Inertia/Cumulative), thus our model is satisfactory.

Table 1. Correspondence analysis – Purchasing enterprises

Dimension	Singular Value	Inertia	Chi Square	Sig.	Proportion of Inertia		Confidence Singular Value	
					Accounted for	Cumulative	SD	Correlation 2
1	.199	.040			.677	.677	.013	.113
2	.106	.011			.192	.869	.013	
3	.072	.005			.089	.958		
4	.050	.002			.042	1.000

a. 60 degrees of freedom

Source: own processing

Figure 2 illustrates correspondence analysis of volume of purchasing cross-border M&A in the respective countries. We note that the lowest volumes of cross-border M&A s(≤ €2,619,000) weakly correspond with the enterprises from Malta, Cyprus, Poland and Greece. Volumes of the cross-border M&A from the second interval (€2,620,000 – €8,975,000) can be found most often in the United Kingdom. Cross-border M&A volumes from the next interval (€8,976,000 – €28,000,000) correspond with the companies from Finland and Denmark. Enterprises from Austria, Italy and Spain implement cross-border M&A most frequently in the volumes from the fourth interval (€28,001,000 – €130,000,000). Enterprises from Germany and France correspond with the cross-border M&As volumes which are higher than €130,001,000.

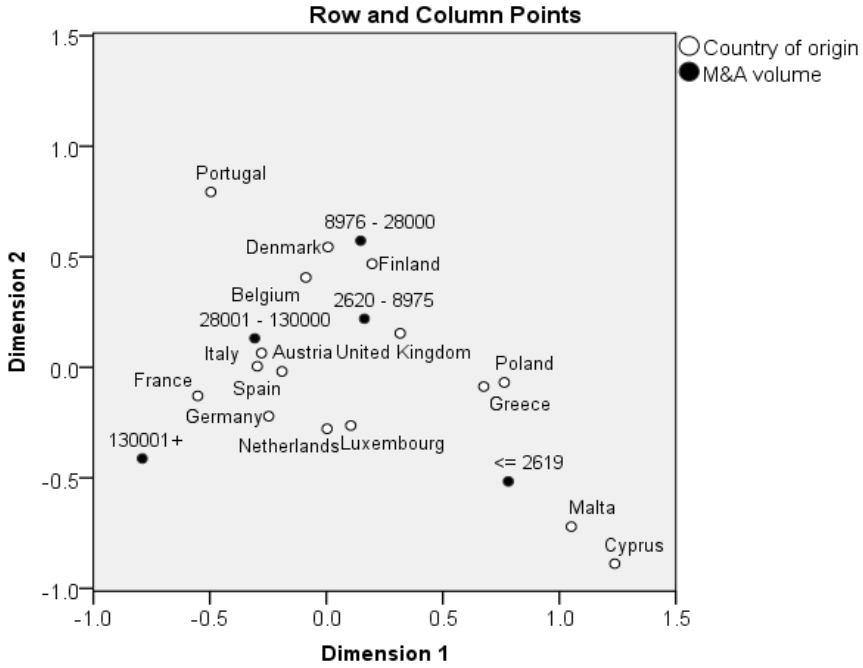

Figure 2. Correspondence analysis – Purchasing enterprises

Source: own processing

3.2 Purchased enterprises – M&A volumes

In terms of the purchased enterprises, we observe cross-border M&A in all counties of EU + Turkey. Table 2 contains properties of correspondence analysis. Pearson's chi-square test p-value is 0.000 (column Sig.), what leads us to rejection of the null hypothesis of non-dependence of data, and we suppose that there exists the dependence between the variables – target country and cross-border M&A volume. Total inertia captured by correspondence analysis is 86.6% (column Proportion of Inertia/Cumulative), thus our model can be seen as satisfactory.

Table 2. Correspondence analysis – Purchased enterprises

Dimension	Singular Value	Inertia	Chi Square	Sig.	Proportion of Inertia		Confidence Singular Value	
					Accounted for	Cumulative	SD	Correlation
								2
1	.258	.066			.729	.729	.015	.093

Figure 3 contains correspondence analysis of the volume of cross-border M&A in the target countries.

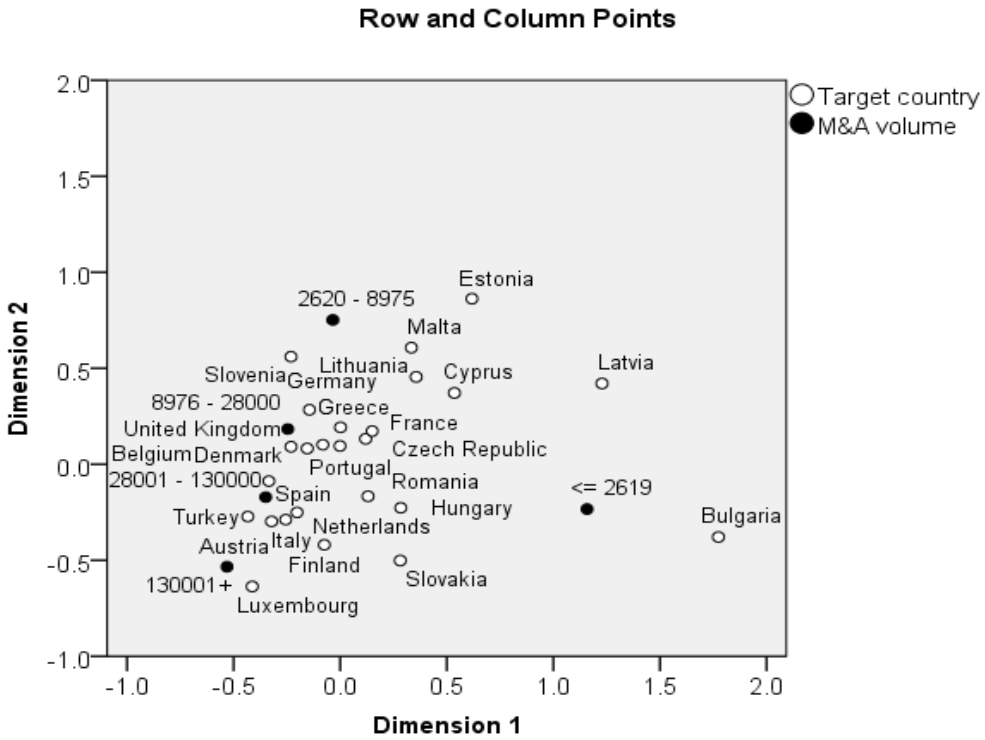

Figure 3. Correspondence analysis – Purchased enterprises

Source: own processing

We observe some clusters formed by the target countries of cross-border M&A and the volumes of M&A. No specific country is strongly associated with cross-border M&A volumes from the first interval (≤ €2,619,000). Cross-border M&A volumes from the next interval (€2,620,000 – €8,975,000) are mostly present in Malta and Slovenia. Cross-border M&A volumes from the third interval (€8,976,000 – €28,000,000) were carried out most frequently in Greece, France, Czech Republic, Portugal, Denmark, Belgium and United Kingdom. Cross-border M&A with the volumes from the

fourth interval (€28,001,000 – €130,000,000) were seen during 1998-2022 in Spain, Turkey, Italy and Netherlands. Cross-border M&A with the volume bigger than €130,001,000 relatively closely corresponds with Luxembourgian enterprises.

4. Discussion and Conclusions

Ease of access, more information, or the unity of standards, norms and rules of the European market have contributed to increased tendencies of M&A investment among EU Member States. The most important reasons for M&As in the period under review were the restructuring of entities, the improvement of the balance of payments, and the acquisition of a larger market share. Mergers and acquisitions are complex and demanding processes, both legally and economically. A merger is preceded by an evaluation of the value of the participating companies, their liabilities, indebtedness, and other determinants that will reveal whether or not the planned merger or acquisition is beneficial. The main objective of the paper, based on correspondence analysis, was to analyze the volume of cross-border mergers in the Member States of the European Area in the period of 1998-2022, which was monitored in the target and the source countries of the European Area. Using correspondence analysis, we have divided the volume of the implemented cross-border mergers and acquisitions into five intervals for which the following values apply: (≤ €2,619,000), (€2,620,000 – €8,975,000), (€8,976,000 – €28,000,000), (€28,001,000 – €130,000,000), and (€130,001,000 ≤).

Based on the results of the analysis, the lowest implemented M&As volumes were recorded in Malta, Cyprus, Poland and Greece among the purchasing companies. Their value was less than or equal to €2,619,000. The largest volumes of mergers and acquisitions were recorded in Germany and France. Their value was over €130,001,000. This stems from the basic assumption that in an economy that is in a growth phase, individual entities are able to accumulate a larger volume of capital resulting from its higher evaluation, which may be the result of an increased consumption of entities on the domestic market, or by increasing the demand on foreign markets (competitiveness increase). Mergers and acquisitions in Germany and France within the countries of the European area were the best option for companies in the reporting period of 1998-2022 to gain a significant market position. In the case of the purchased companies, the highest volume of mergers and acquisitions was in Luxembourg with a value equal to or greater than €130,001,000.

In the period of 1998-2022, the purchased companies were affected by the transformation of economies into a market economy, which led to more intensive redemptions of companies, which could pose a competitive risk in the future (they had not yet been restructured and the production processes had not been streamlined) and a relatively low market valuation at the time, particularly from the perspective of the acquiring country. The lowest volume of mergers and acquisitions was in Malta and Slovenia in the reporting period, amounting to €2,620,000 – €8,975,000. From the results of the analysis we can conclude that neither country achieved the same volume of mergers and acquisitions, which applies both to the target and the source countries. The incentive for businesses to carry out mergers and acquisitions within the European Union is consistent with efforts to strengthen their position in one of the largest common markets. This is mainly related to the uniform compliance with standards and the compatibility of permits between the Member States of the Union, or better awareness of all essential requirements.

Analysis of Performance Indicators of Small and Medium-sized Enterprises in the European Union

***Jaroslav* Korečko**[1,*] **and *Ján* Vravec**[1]

[1] University of Prešov, Department of Finance, Accounting and Mathematical Methods, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Small and medium-sized enterprises are key employers in all Member States of the European Union. In Slovakia, they are also crucial for economic performance, job creation, and value-added. For the European industrial strategy of progress and advancement, SMEs represent a key tool for innovation in many sectors across the economy.
Purpose of the article: SMEs were the largest employers in the European Union in 2023. The sectors with the largest number of employees also produced the largest share of value added. The article aims to examine the status and development of selected indicators on small and medium-sized enterprises in the European Union and Slovakia. It will bring new insights, reveal problem areas, and propose solutions in the subject area.
Methods: Secondary data obtained from databases, reports, and studies dealing with the issue of small and medium-sized enterprises will serve as a basis for the analysis of selected indicators for recent years. The result´s comparison in space and time will provide the opportunity to monitor the status and development of SME indicators.
Findings & Value added: SME´s support and financing is a matter of survival for each individual economy and the economy of the entire integration group. It is necessary to focus economic and political efforts on the part of government authorities on their constant encouragement so that they can survive even in times of crisis and ensure stability in economic development and employment.

Keywords: Small and Medium-sized enterprises, European union, Net turnover

JEL classification: E24, E32

1. Introduction

The COVID-19 pandemic profoundly impacted every European country and its economy. While measures to save lives and protect health were essential, they inevitably led to significant economic repercussions. The longer these restrictive measures persisted, the more challenging it became for businesses across various sectors to endure their effects. Interestingly, large businesses and micro-enterprises appeared to demonstrate the greatest resilience during this period, relatively quickly returning to their original levels of production, sales, or service provision once the pandemic subsided.

This paper aims to examine and evaluate the status and development of small and medium-sized enterprises (SMEs) within the European Union over the past three years. Despite traditional significant regional disparities in economic performance and indicators, SMEs remain indispensable entities across all Member States. They are vital employers, generate substantial added value, and fulfil demand for a wide array of specific goods and services.

The existence and prosperity of SMEs are influenced by numerous factors, both anticipated and unpredictable. Supporting and financing small and medium-sized enterprises, though often less publicized than efforts for large corporations and investors, is a crucial responsibility for authorities. Such support drives innovation, fosters progress, creates jobs, and delivers considerable added value to regional, national, and the broader European economy.

2. Theoretical background

In 2023, SMEs accounted for 99.8% of all companies and 53.3% of added value. SMEs are the backbone of the EU labour market, employing a large share of the workforce. In 2023, 26 million SMEs employed around 89 million workers in the European Union. (Shultze et al., 2025) This fact evidences how these companies are crucial to the global economy. SMEs are characterized by close relationships with customers, employees, and suppliers (Mayr et al., 2017), and this proximity allied to entrepreneurship favours the long-term competitiveness of these companies. (Pérez-Luño et al., 2016)

SMEs are at the heart of innovation and entrepreneurship. The ideas and solutions of 26 million entrepreneurs, women and men, contribute to a sustainable and digital economy, central to Europe's competitiveness. The European Commission is committed to supporting enterprises from the moment they start, throughout their lifetime. (Dachs et al., 2022)

European Commission Recommendation 2003/361 defines small and medium-sized enterprises as companies whose number of employees and economic weight do not exceed certain thresholds.

A medium-sized enterprise has no more than 250 employees, a turnover of no more than EUR 50 million, and a balance sheet not exceeding EUR 43 million. A small enterprise has no more than 50 employees and a turnover or balance sheet of no more than EUR 10 million. A micro-enterprise has no more than 10 employees and a turnover or balance sheet of no more than EUR 2 million. (European Commission, 2025)

Over 26 million SMEs operate in the European Union, representing 99% of all enterprises and providing two-thirds of private sector jobs. They are a key driver of the economy.

The EU encourages the use of this definition of SMEs as a reference, including by EU Member States. Furthermore, the definition is only binding for particular areas, such as State aid and the implementation of Structural Funds or other EU programs. (Ploeger & Prutch, 2025)

There are various EU programs to support work on SME-related issues, notably the Single Market Programme.

Small and midsize enterprises can exist in almost any industry but are more likely to operate within industries with fewer employees and smaller up-front capital investments. The most common types of SMEs include legal firms, dental offices, restaurants, and bars.

SMEs are segregated from large, multinational corporations because they fundamentally operate differently. Large, complex firms may require advanced enterprise resource planning (ERP) systems—for accounting, supply chain management and financial reporting, and interconnectivity across offices around the world—or deeper organizational processes. SMEs, on the other hand, may require fewer systems given their narrower scope of operations.

Small businesses also have distinct advantages over larger companies (Liberto, 2025):

- SMEs can often operate more flexibly. Large companies with broader processes touching more employees may find it more difficult to act as nimbly.
- SMEs often garner a stronger sense of community. Slogans such as "shop local" are geared toward supporting SMEs that don't have branches across the nation.
- SMEs are more likely to financially support their community. Instead of collecting revenue and investing it in a new store across the country, SMEs are more likely to remain local, sustain local businesses, contribute local tax dollars, and buy from nearby suppliers.
- SMEs may be engrained with a rich history. Larger, complex companies may have a long history as well (especially if they've been financially successful). However, SMEs are more likely to carry family traditions, preserve how generations have done things, and pass down the family business.
- SMEs may have a narrower, more direct focus than larger businesses. Think of Apple (AAPL). Developing iPhones, iPads, Macs, Apple Watches, accessories, and streaming services requires the staff to support each of these departments. However, an SME with limited staff must limit the scope of what it offers. Instead of attempting to have a broad market presence, successful SMEs often deeply integrate themselves into a smaller target market.

Forecasting key financial indicators of enterprises such as revenues, costs, and profitability is critical for setting the right corporate strategies, achieving long-term stability, and ensuring the competitiveness of businesses. Profit forecasting is essential for managing cash flow, ensuring

liquidity, and evaluating business strategy. (Jenčová et al., 2025) If the business achieves a negative Economic Value Added, it is inefficient and may have competitiveness problems due to problems with its performance. (Horváthová & Mokrišová, 2020)

The competitiveness of companies is determined by institutions, policies and other factors, determining their continued presence in the market, profitability and ability to adapt production to demand. (Chao et al., 2015) In Small and Medium Sized Enterprises focused on high technology launching new products is an important way to maintain their competitive advantage (Pan et al., 2018). It can be noticed that several factors influence in the competitiveness of companies and it is important to determine these factors and the areas in which they can gain competitive advantage. The strength of organizations is determined by their competitiveness and the strategies they adopt to gain competitive advantage and strengthen their positions in the market (Nara et al., 2015)

3. Methods

The European Statistical Office database contains data on small and medium-sized enterprises by number of persons employed. The data in the tables have been aggregated, analysed over time and space, and converted into relative units for relevant comparison. To calculate the average trend indicator, we used the *Average Annual Growth Rate (AAGR)*. It is determined by taking the numerical mean of specified or calculated year-on-year growth rates. The formula is following:

$$\mathrm{AAGR} = \frac{[(Growth\ Rate)y + (Growth\ Rate)y + 1 + \cdots (Growth\ Rate)y + n]}{N(1)}$$

Where:
Growth Rate (y) – Growth rate in year 1
Growth Rate (y + 1) – Growth rate in the next year
Growth Rate (y + n) – Growth rate in the year "n"
N – Total number of periods

Since practical data mining problems high-dimensional data are clustered, the resulting clusters are high-dimensional geometrical objects which are difficult to analyse and interpret. A low-dimensional graphical representation of the clusters could be much more informative than such a single value of the cluster validity one can cluster by eye and qualitatively validate conclusions drawn from clustering algorithms. (Abonyi and Balázs, 2007, Ward, 1963)

We have used the non-hierarchical K-means clustering method to cluster countries. A significant part of these degrees of similarity is based on the calculation of the distance between objects. (Meloun et al.,2012) The Euclidean distance we used is defined by the formula:

$$\mathrm{d}_{ij} = \sqrt{\sum_{k=1}^{K} \left(x_{ik} - x_{jk}\right)^2}$$

Where x_{ik} is the value of k variable for *i-th* object and x_{jk} is the value of k variable for *j-th* object. For calculated distance is than determined the rule of linking statistical units into clusters.

4. Results and Discussion

The EU-27 gross domestic product increased by 0.5% in 2023 compared to the previous year. Growth was moderate, especially compared to 2021 (6%) and 2022 (3.4%) when the economic recovery after the pandemic was still relatively strong. The period between 2021 and 2023 presented a challenging economic environment, characterized by significant uncertainties. This naturally influenced SME access to financing and overall performance. Rising inflation emerged as a primary challenge. Although nominal value added increased in 2023, all SME size classes experienced a real-term decline. Micro-enterprises demonstrated the most resilience, likely due to their enhanced flexibility in adapting to macroeconomic shifts and quicker recovery from shocks compared to larger firms. Small enterprises recorded the most significant decrease in value added (-2.4%), with SMEs collectively experiencing a more pronounced decline (-1.6%) than large enterprises (-1.1%).

Conversely, employment maintained a positive growth rate, with micro-enterprises again showing the highest growth among SMEs. The number of enterprises also increased across all monitored categories, extending the trend observed in 2022.

Source: authors according Eurostat data (2025)

Table 1 shows the development of the number of SMEs in the period 2021-2023. The largest number of small and medium-sized enterprises is naturally in the most powerful European economies, France, Italy, Spain, and Germany. However, the trend in the number of enterprises differs in individual Member States. Compared to 2022, the number of SMEs decreased in Belgium, Ireland, and Hungary.

The highest AAGR within the Union was recorded in Estonia (an average increase of approximately 9.2%). Comparing the number of enterprises decreased the most on average in Luxembourg (a decrease of roughly 3.8%). The other columns of the table show the enormous predominance of enterprises with 0 to 9 employees within all SMEs. Only Luxembourg is below the 90% threshold.

There are currently approximately 30 million enterprises and companies operating in the European Union. The vast majority of these enterprises are micro-enterprises, but large enterprises produce up to half of the turnover. The highest turnover-achieving companies are focused on industry, followed by trade and construction.

Table 2. Number of employed persons by SMEs in the EU-27 (industry, construction and market services)

Source: authors according Eurostat data (2025)

Table 2 provides information on the number of people employed in SMEs in recent years. According to the EU-27 median, enterprises with 0 to 9 employees employ approximately 47.94% of all workers.

The highest value of the indicator in 2023 was achieved in Slovakia, the lowest in Luxembourg, followed by Denmark. The development trend was increasing in almost all economies. A decrease occurred only in Latvia, Hungary, and Poland.

According to AAGR, the number of people employed grew most significantly in Cyprus (+21%). In terms of the number of enterprises in the country, Germany dominates SME employment with approximately 6.92 people per enterprise.

Compared to 2021, employment has fully recovered from the pandemic and has maintained a relatively stable pace of improvement in 2023. Similarly, the number of micro, small, and medium-sized enterprises has also grown, which is naturally linked to employment growth.

For European industrial progress and the presentation of SMEs, they are key tools for innovation in many sectors and the entire Union economy. Regular monitoring of the development of SMEs across 14 sectors on an annual basis has become unique in terms of their significant contribution to all key indicators (in particular employment, turnover and public value).

Source: authors according Eurostat data (2025)

Table 3 illustrates the turnover of SMEs across individual years. The overall trend in turnover development among Member States is largely consistent, with decreases compared to 2023 observed only in Denmark, Italy, Luxembourg, Austria, and Sweden.

Nevertheless, the Average Annual Growth Rate of net turnover across all economies is close to 1, signifying average annual growth for this indicator. The highest values were achieved by Cyprus and Portugal. Romania and Bulgaria also recording significantly higher average growth compared to other nations.

In 2023, the median net turnover for SMEs with 0-9 employees was 32.88%. The final column of the table presents net turnover normalized by the number of enterprises. Luxembourg clearly dominates this ranking, with over 4 million euros per SME.

Cluster analysis aims to reveal mutual similarities between 27 Member States based on further analysis of previous research data. Preceding quantitative and graphical analyses indicate differences in the development of three selected indicators. Therefore, we decided to use that statistical tool to analyse multidimensional data.

Three imputed variables for the Member States were AAGR of SMEs number, employed persons per enterprise, and the net turnover per unit. The objective of cluster analysis was to achieve such groups of states, which would be characterized by certain homogeneity in case of selected indicators.

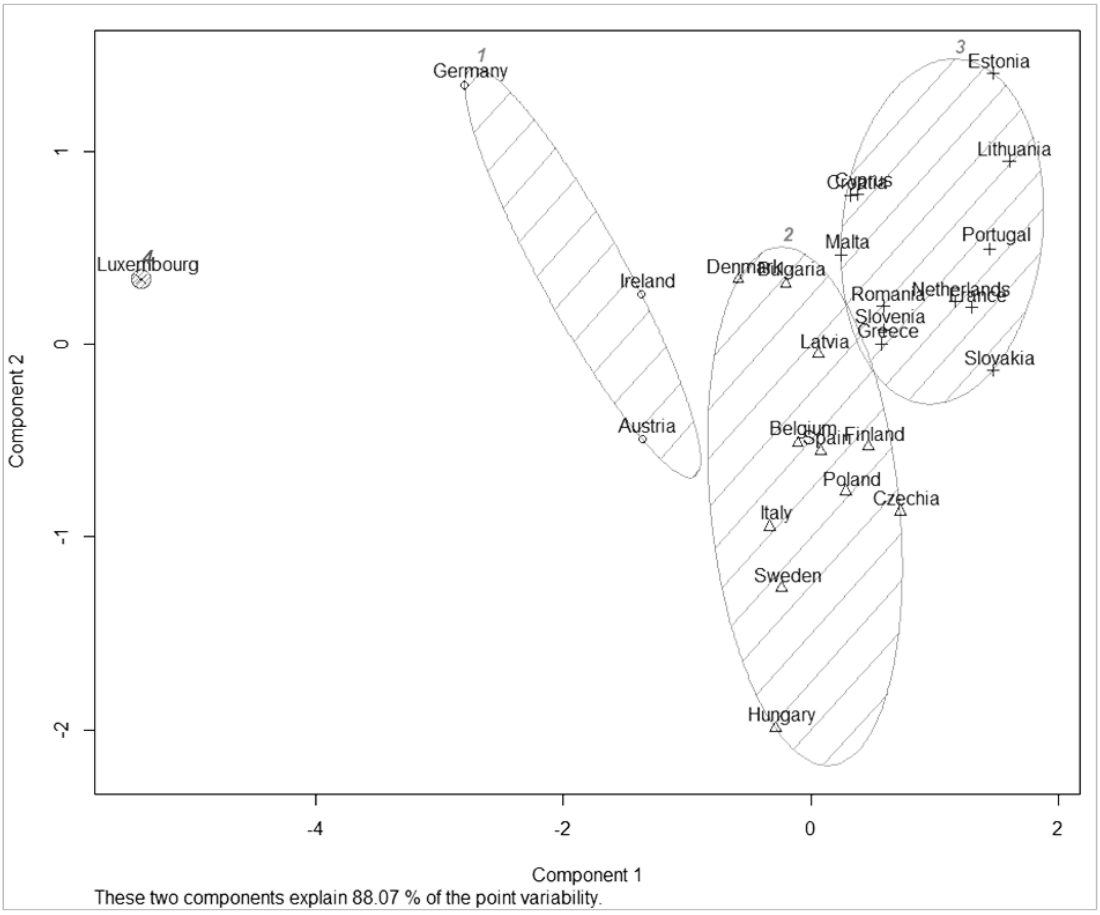

Figure 1. Scatterplot according to K-means method
Source: authors (2025)

To draw conclusions that consider the exact distances, we have also used a non-hierarchical clustering K-means method, which involves two main clustering components (variables). The output of that kind of clustering is a scatterplot. (Figure 1.)

If we consider two variables, clusters are visualized by using the non-hierarchical method. K-means clustering is the most popular partitioning method. It requires the analyst to specify the number of groups to extract. There are two components, which explain 88,07 % of the point variability. Due to testing, we have chosen 4 clusters as an imputed command for a new clustering. We consider the data set, which contains n=27 objects. The essence of ellipses is the average and the covariance matrix of each cluster. Their size is such that they include all the points of their group. The ellipses sizes of all clusters are different. Group of countries no. 1 displays greater variability for Component 2 because of an object on the boundaries of the ellipse (Germany). The denser shading intensity indicates the greater density of divided countries in ellipses. The most tightly arranged countries are in cluster no. 3.

Conclusion

Micro, small, and medium-sized enterprises are the driving force of the European economy. They significantly contribute to job creation, economic growth, and social stability. Furthermore, SMEs stimulate entrepreneurial spirit and innovation across the EU, making them essential for fostering competitiveness and employment.

Given their profound importance to the European economy, SMEs are central to EU policy. The European Commission is committed to supporting entrepreneurship and enhancing the business environment for SMEs, thereby enabling them to fully realize their potential in today's global economy.

Micro, small, and medium-sized enterprises have consistently served as principal employers across all European Union Member States. In Slovakia, their significance extends to economic

performance, job creation, and value added. Microenterprises, in particular, represent the dominant size group within Slovakia. Throughout the EU, microenterprises are most prevalent in sectors such as retail, information technology and services, and culture. Among all sectors, retail and construction clearly generate the highest added value.

The period following the COVID-19 pandemic proved to be a favourable phase for the emergence and development of SMEs in both Slovakia and other Member States. Naturally, microenterprises, being the most susceptible to economic, legislative, and political changes among SME categories, exhibited the largest fluctuations in entity numbers in recent years.

Given that SMEs constitute over 99% of all enterprises in the European Union, they are fundamental to its economy. Therefore, their support and financing are crucial for the survival of individual national economies and the entire integration group. It is thus imperative for governmental authorities to direct economic and political efforts towards continuously fostering SMEs, enabling them to withstand crises and ensure stability in economic development and employment.

Subsidies as a Tool for Increasing the Competitiveness of Slovak Farms

Ivana Kravčáková Vozárová[1,*], _Rastislav_ Kotulič[1], and _Omar_ Mohamad Abdulhafiz Mhemed[1]

[1] University of Prešov in Prešov, Department of Economics and Economy, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Supporting the competitiveness of agricultural enterprises is one of the main priorities of the European Union's Common Agricultural Policy. Therefore, analyzing the effectiveness of its implementation is a crucial element in evaluating this policy. However, the issue of providing subsidies in agriculture is highly debatable both in Slovakia and the EU, raising various conflicting opinions in the long term.
Purpose of the article: The aim of this partial contribution is to analyze that subsidies contribute to enhancing the competitiveness of Slovak agricultural enterprises. The paper also evaluates how subsidies affect the financial stability of agricultural entities and their ability to respond to changing market conditions.
Methods: In examining competitiveness, we applied Porter's generic cost minimization strategy, measured using the Recourse Cost Ratio as a ratio indicator. This contribution focuses on entities operating on agricultural land in Slovakia during the period from 2004 to 2019, encompassing 16 years.
Findings & Value added: Based on available data from Slovak farms, key factors for the successful use of support are identified, along with potential risks associated with the improper or inefficient use of subsidies. The results of the analysis provide recommendations for improving subsidy policies and strengthening the competitiveness of the Slovak agri-sector.

Keywords: subsidies, competitiveness, farms, Slovak Republic

JEL classification: Q14, Q18, H20

1. Introduction

The agri-food sector holds significant cultural and social importance in Europe due to its strong tradition and contribution to maintaining rural economies and preserving rural areas across the EU. The topic of agriculture is extensive and undoubtedly current, intersecting with themes such as rural development, industrial innovations, sustainability, circular economy, and consumerism (Schmerber et al., 2022). Agriculture in the European Union is highly diverse, and one of the objectives of the EU's Common Agricultural Policy is to enhance its competitiveness. Therefore, research concerning the competitiveness of agriculture is highly valuable and aids in making strategic decisions related to the agricultural sector at both national and European levels (Nowak & Rózanska-Boczula, 2022).

The concept of competitiveness and its associated term, competitive advantage, represent a multifaceted notion that can be studied and analyzed at various levels, including the enterprise, sectoral, and national levels. Among these levels, measuring competitiveness at the enterprise level in the agricultural sector has received significant attention from researchers and experts. Notable recent studies in this area include those by Kargi and Bachev (2024), Dabkiene (2025), Fuksová et al. (2024), Gazzarin et al. (2024), Georgieva et al. (2025), Kravčáková Vozárová and Kotulič (2025), and

[*] Corresponding author: ivana.kravcakova.vozarova@unipo.sk

Palenychak et al. (2024). It's entirely unsurprising to understand how, in this fast-paced business environment, every company is required to be increasingly competitive and efficient. From a microeconomic perspective, competitive advantage represents a company's ability to offer products and services that meet or exceed customer needs, surpassing what competitors offer at a given time. Therefore, a company's competitiveness encompasses its ability to create, innovate, produce, and sell goods and services in national or international markets, thereby maintaining and enhancing its market position (Sachitra & Chong, 2016; Martinez et al., 2014).

Unlike most other sectors, agriculture is subject to certain unique characteristics that influence its competitiveness (Martinescu, 2019):

- despite the importance of food production, the average income of farmers is approximately 40% lower compared to the average income of other EU citizens;
- agriculture is more dependent on natural and climatic conditions and weather than many other sectors;
- there is an inherent time gap between consumer demand and farmers' ability to supply. For instance, cultivating a larger quantity of wheat or producing more milk necessarily requires time, during which farmers should operate sustainably and ecologically to be cost-effective, maintain soil fertility, and preserve biodiversity.

According to Boháčiková et al. (2021), agricultural enterprises are influenced by specific risks that are not common in other sectors of the economy. The typology of agricultural risks is a key tool for identifying and effectively managing the various threats faced by the agricultural sector, which can be divided into several main categories (see Table 1).

Table 1. Typology of Agricultural Risks

	Micro-level risks	**Meso-level risks**	**Macro-level risks**
Production	Hailstorms, frosts, animal and plant diseases, human risks (illness, death), property risks	Landslides, pollution, rainfall amounts	Drought, pest infestations, floods, transmissible diseases, technology
Market/Price		New regulations in the agricultural sector, land price changes	Input and output price changes, market condition changes, supply shocks, changes in competition, etc.
Financial	Liabilities, indebtedness, income changes, receivables		Interest rate changes, exchange rates, asset values, credit provision
Institutional		Changes in local laws and regulations	Changes in economy-wide legislation, environmental regulations, subsidies

Source: own processing according to OECD (2009) and Boháčiková et al. (2021)

Agriculture is an economically weak sector often influenced by natural and economic factors. Due to the generally higher elasticity of supply compared to demand, agricultural production is subject to significant fluctuations. Subsidy policy is one of the state intervention tools that can stabilize agricultural production and markets (Tan et al., 2013). The primary goal of subsidies is to support farmers in increasing productivity, especially when subsidies are tied to inputs.

Determinants of agricultural competitiveness within the European Union have been extensively studied at both the enterprise and sectoral levels. In Slovakia, the competitiveness of farms is influenced by internal factors such as productivity, innovation, and farm management, as well as external factors including political and economic decisions at the EU level. EU financial

support plays a crucial role in enhancing the competitiveness of Slovak farms. Therefore, it is important to analyze the impact of this financial support on the competitive position of farms in Slovakia within a broader context.

2. Methods

The presented partial contribution, within the framework of a comprehensive research project, focuses on a set of entities operating on agricultural land in Slovakia during the period from 2004 to 2019, encompassing 16 years. The aim is to analyze how subsidies contribute to enhancing the competitiveness of Slovak agricultural enterprises. In line with the established objective of the study, the following hypothesis was tested: *"We assume that there are statistically significant differences in the competitiveness of agricultural enterprises, measured by the RCR index, between those receiving subsidies and those not receiving subsidies."*

In examining competitiveness, we applied Porter's generic cost minimization strategy, measured using the Recourse Cost Ratio (RCR) as a ratio indicator in the following form (Rumanovská, 2010):

$$RCR_i = C_i/R_i$$

where:

- C_i represents the costs in year *i,* including procurement costs, production consumption, personnel expenses, depreciation, taxes, and fees.
- R*i,* represents the revenues in year *i,* encompassing sales revenues, production, and subsidies.

This ratio is particularly useful in evaluating the impact of subsidies on the financial performance of agricultural enterprises. The data for this analysis were obtained from agricultural enterprises and provided by the Ministry of Agriculture and Rural Development of the Slovak Republic in the form of anonymized Information Sheets. The research sample (Table 2) included only those enterprises that maintained consistent financial records throughout the study period and ensured accurate and balanced reporting in their financial statements. This approach ensured a comprehensive and standardized dataset, facilitating a robust analysis of the financial performance and competitiveness of Slovak agricultural enterprises during the specified period.

3. Results

Agriculture and the agricultural sector are often undervalued and may seem unattractive or uninteresting from the perspective of ordinary consumers. However, this sector represents a complex system that plays a key role in meeting people's needs, protecting the environment, supporting economic development, and preserving cultural identity. It influences the daily lives of individuals and the functioning of the country in terms of food security. It constitutes a complex system that is essential for sustainable development and the well-being of society.

Upon examining Figure 1, a significant difference in competitiveness levels is evident between agricultural enterprises that receive EU subsidies (RCR SUB) and those that do not (RCR nSUB). The figure clearly shows that subsidies substantially contribute to the revenue side of the Recourse Cost Ratio (RCR) coefficient, thereby reducing its value.

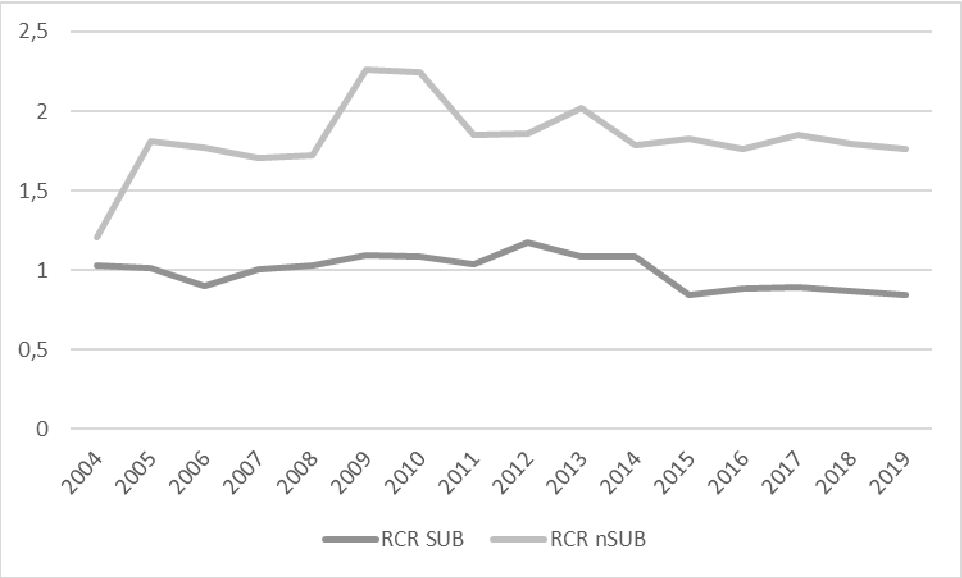

Figure 1. Wilcoxon signed-rank test
Source: authors (2025)

To test the established hypothesis, we used the Wilcoxon signed-rank test, the results of which are presented in Table 3. This test confirmed the existence of statistically significant differences in the competitiveness of agricultural enterprises between those receiving and not receiving subsidies. Based on the research conducted, it can be concluded that EU subsidies have a significant impact on the competitiveness of agricultural enterprises in Slovakia. The results indicate that subsidies support the income side of farms and improve the overall cost-to-revenue ratio, reflecting better cost-effectiveness. These subsidies contribute to increasing the competitiveness of agricultural enterprises by enabling farms to better cover their costs, which can positively impact their ability to compete in the market both in the short and long term.

4. Discussion

The question of the impact of subsidies on the competitiveness of agriculture is a very broad topic. Gozora (2021) argues that competitiveness is influenced by both external and internal determinants of the economic environment, which shape the conditions for business activity, form the entrepreneurial structure, and are decisive factors for economic growth and the economic differentiation of business entities. Last but not least, decisive factors for economic development are imbalances in production, sales, and monetization of products and services, which are sources of security risks and crisis phenomena in the business of agricultural entities. Therefore, protecting enterprises from adverse influences of the external and internal environment is an integral part of agricultural management.

The financial management of agricultural enterprises is influenced by a range of factors that are not present in other sectors. Kravčáková Vozárová et al. (2019) examined the impact of the legal or organizational structure on the performance of agricultural enterprises in Slovakia. Their study revealed that the legal form of a farm significantly influences its economic outcomes. By analyzing two types of agricultural entities—agricultural cooperatives and business companies—over the period from 2005 to 2014, the authors found that these entities exhibited distinct financial performances across various indicators. This analysis, employing mathematical and statistical methods, confirmed that the legal structure is a determining factor in the economic performance of agricultural enterprises in Slovakia.

Natural and climatic conditions and agriculture are inextricably linked and mutually influence each other. Undoubtedly, agriculture is one of the sectors most at risk from climate change, and these conditions have multiple impacts on the agricultural sector—primarily through changes in productivity and yields, as well as changes in the agri-food market.

According to Kotulič et al. (2018), the relationships between climate change and agriculture are complex and diverse. The factors influencing the climate are constantly changing, and this phenomenon has a multidimensional impact on human livelihoods. As these conditions evolve, indicators related to agricultural sustainability—such as production volume, yields, areas, and production values—also change.

When agricultural sustainability becomes vulnerable, it leads to fluctuations in economic indicators such as total production volume, crop and final product profit margins, and wage rates (Alam et al., 2013). In addition, climatic factors influence the social and economic sustainability of farmers, both directly and indirectly. They cause crop damage, which results in low productivity and high production costs, leading to loss of income for farmers, increased poverty levels, and higher rates of seasonal unemployment Agriculture is a fundamental pillar of the national economy, ensuring not only the nutrition of the population but also job creation and economic stability. Although it may seem unattractive at first glance, its significance is invaluable. This sector influences the daily lives of individuals. Farm management is the operational aspect of agricultural activity. It encompasses strategic planning and the implementation of decisions regarding resource utilization within the agricultural entity. Financial planning serves as the foundation of the entire farm management process. Subsidies can play a significant role in enhancing farm efficiency; however, their impact depends on their design and the broader agricultural context. To maximize positive effects, it is essential to tailor subsidy programs to the specific needs of farmers, support decoupled payments, and ensure that subsidies promote sustainable and effective agricultural practices.

Conclusion

The Common Agricultural Policy (CAP) is one of the European Union's oldest policies, established in 1962, and has been instrumental in shaping the agricultural sector for over 50 years. A distinctive feature of agriculture is its regional differentiation, encompassing both agrarian structures and natural and non-natural conditions. Issues related to the study of agrarian structures have consistently been a focal point, becoming particularly significant in the context of adapting farms in EU countries to compete in the EU's single market.

From this perspective, it is evident that numerous factors contribute to transforming comparative advantages to enhance business competitiveness. One avenue for enterprises is the broader adoption of new technologies, which, however, requires effort from both economic and knowledge management standpoints. Managing and leading an agricultural enterprise necessitates recognizing that a farm is

primarily a business entity aiming to maximize profit. Therefore, it is essential to build upon rational management concepts, with a fundamental aspect being a proper understanding and setting of the enterprise's production costs.

The most general characteristic of any economic activity is decision-making. Proper management and implementation of the decision-making process at the farm level should involve organization and operation aimed at higher productivity and maximum profit. Effective farm management is a key idea for increasing competitiveness, productivity, and profitability of any agricultural enterprise.

Underexplored Factors of Fiscal Outcomes in the Slovak Local Public Sector: Gender Standpoint

***Lenka* Maličká**[1,*] **and *Dominika* Jusková**[1]

[1] Technical University of Košice, Department of Finance, Faculty of Economics, Němcovej 32, 040 01 Košice, Slovakia

Abstract

Research background: The literature underexplores gender determinants of local fiscal outcomes in Slovak conditions, even though the increase of female local elected authorities in Slovakia in the last decades is evidenced. Furthermore, the differences in gendered leadership are well-known and examined in the gender literature worldwide.
Purpose of the article: The paper examines the relationship between the women mayor variable and municipal tax revenues, the main fiscal outcome of local budgets. The paper aims to decrease the gap in the literature that focuses on gender topics in Slovak conditions.
Methods: The main research method is regression analysis of panel data. Fixed-effect and Random-effect models are employed to estimate the relationship between the women mayor variable and municipal tax revenue in the sample of all 2,296 Slovak municipalities from 2005 to 2024.
Findings & Value added: The paper´s results show a positive relationship between the representation of women mayors and local tax revenues. The paper contributes to the gender literature by examining local tax revenue determinants regarding the determinants of non-economic character - the gender standpoint of the mayors ' personal characteristics.

Keywords: Local government, Mayor, Gender, Local revenue, Tax revenue

1. Introduction

Although increasingly popular in recent years, the gender of local elected authorities is still underestimated and insufficiently analyzed as a determinant of local fiscal outcomes. This exogenous factor has, in recent years, become an increasingly discussed topic of scientific interest, as confirmed by research by foreign authors (e.g., Geys and Revelli, 2011; Cabaleiro & Gómez, 2017; Slegten et al., 2019; Cabaleiro-Casal & Buch-Gómez, 2020; Jung, 2022; Cuadrado-Ballesteros, Guillamón, and Ríos, 2021; Balaguer-Coll & Ivanova-Toneva, 2021; Avellaneda et al., 2022).

Among the local fiscal outcomes, a significant part of the local public finance and fiscal decentralization literature is dedicated to local tax revenues. This branch of literature gradually introduces variables focusing on the gender of local authorities. For instance, Geys and Revelli (2011) demonstrated that the gender of Flemish (Belgian) elected representatives in local politics influences property tax levels. Slegten et al. (2019) confirmed that female elected representatives in Belgium, in an effort to reduce fiscal deficits, tend to prioritize increasing public revenues (raising local taxes and, subsequently, municipal tax revenues), while their male counterparts prefer expenditure reductions. Jung (2022), who analyzed whether the gender of elected political authorities at the local level affects budgets in Korean cities, including the level of decentralization in the country, found evidence of such a relationship. However, according to him, there is little proof that the gender of local elected authorities truly affects local governments' budgets and revenue levels (including tax revenues). His results suggest that the level of local tax revenues depends not only on the gender of elected authorities but also on various socio-economic factors (such as crises and reforms), which he considers to be more significant than gender. Cabaleiro and Gómez (2017) acknowledged the possible relationship between the gender of

* Corresponding author: lenka.malicka@tuke.sk

elected political authorities and municipal tax revenues. However, they argued that female elected representatives in Spanish local governments are associated with lower levels of tax revenues, thereby deepening fiscal imbalances in local budgets. Conversely, Cuadrado-Ballesteros, Guillamón, and Ríos (2021), also analyzing Spain, found that municipalities with female elected authorities tend to underestimate revenues and overestimate expenditures. This holds not only for mayors but especially when there is sufficient representation of women in local councils. According to the authors, women in local governments can thus contribute to the financial health of municipalities. In contrast, Cabaleiro-Casal and Buch-Gómez (2020) identified that female elected representatives worsen Spanish local governments' fiscal performance, which contradicts most empirical studies' hypotheses.

In Slovak conditions, only limited resources on the nexus of gender and local fiscal outcomes could be found (Maličká & Mourao, 2024). However, the examination of women's representation in local politics has wider roots (e.g., Maškarinec and Klimovský, 2017; Lukáčová & Maličká, 2023), and the increase of women mayors is observed.

In this paper, we analyze whether the mayor's gender impacts the development of individual local tax revenues and their individual categories in the Slovak Republic. We employ standard estimation techniques, such as fixed-effect and random effect models, to examine the relationship mentioned above in the sample of all 2,926 Slovak municipalities, as the Ministry of Finance of the Slovak Republic reported.

The paper´s motivation is that the gender determinants of local fiscal outcomes in Slovak conditions are underexplored in the literature, even though the increase of female local elected authorities in Slovakia in the last decades is evidenced, and the differences in gendered leadership are well known and examined in the gender literature worldwide. The paper contributes to the gender literature by examining local tax revenue determinants regarding the determinants of non-economic character - the gender standpoint of the mayors ' personal characteristics.

2. Methods

The paper sample consists of 2,926 municipalities with elected local representatives and creating their own local budgets as reported by the Ministry of Finance of the Slovak Republic (abbreviated as MF SR). The time span is 2005-2024, thus working with all available data. The final data set is an unbalanced panel.

In this paper, the main research method is panel regression analysis. The paper examines the relationship between the women mayor variable and municipal tax revenues using standard estimation techniques for panel data, the fixed-effect model (FEM), and the random-effect model (REM). According to Baltagi (2021), panel regression is an extended version of time series regression, with the addition of a cross-sectional dimension that allows us to observe the individual effects of variables on the dependent variable. The FEM is applied in cases where individual characteristics exist that are constant over time and may influence the dependent variable:

$$y_{it} = \beta^T x_{it} + \mu_{it} + \varepsilon_{it} \quad (1)$$

where μ_{it} represents the fixed effects for the *i*-th observations, and ε_{it} denotes the fixed effects for non-significant variables for the *i*-th observations at time *t*. It is assumed that the error term ε_{it} is not correlated with the explanatory variables x_{it} for the respective *i* and *t*, with the following condition holding:

$$\mu i \sim (0, \sigma_{\mu}^{2}), \varepsilon_{it} \sim (0, \sigma_{\mu}^{2} I), E(\mu_i \varepsilon_{it}) = 0 \quad (2)$$

The REM is used in cases where individual characteristics can be considered random and are not directly included in the model:

$$y_{it} = \alpha + \beta^T x_{it} + u \quad (3)$$

$$u_{it} = \mu_i + \varepsilon_{it} \quad (4)$$

To decide whether FEM or REM is adequate, we conduct a Hausman test with a null hypothesis that GLS estimates are consistent and an alternative hypothesis for the FEM.

The local tax revenue represents the dependent variable in this research. Beside the total local tax revenue, we altern the main dependent variable by employing also tax revenues categories as they appear in local budgets and we follow the economic classification of revenues adopted by the MF SR – e.g., local tax revenues (revenue group 100) contains shared tax (group 110), immovable property tax (group 120) and other local taxes (group 130) (see Table 1). They present particular parts of local total tax revenues. As immovable property tax and other local taxes create own tax revenues of municipalities, we consider their sum as one of the dependent variables, too.

The independent variable, the local tax revenue determinant examined in this analysis, is the gender of the elected political authority, with the assumption that the presence of female mayors in Slovak local governments increases local tax revenues (Slegten et al., 2019; Casarico et al., 2022; Avellaneda et al., 2022). This assumption originates in empirical analyses confirming the positive aspects of women's presence in local politics. Recent research shows that female leaders are more community-oriented (with higher expenditures on healthcare, education, and social policies (Funk & Phillips, 2019) and less prone to corruption (Brollo & Troiano, 2016), which contributes to local development, increased employment, and greater transparency, ultimately leading to higher tax revenues. On the other hand, there are also studies confirming the insignificance of the gender of elected political authorities (Jung, 2022), or even an adverse effect of female mayors on the tax revenues of local governments (Cabaleiro & Gómez, 2017; Cabaleiro-Casal & Buch-Gómez, 2020). We created a binary variable to capture the gender dimension of local government leadership in econometric calculations. This variable takes the value of 1 if the mayor is a woman and 0 if the mayor is a man. This approach allows for precise quantification and subsequent analysis of the impact of gender representation on the observed outcomes within the context of this determinant. Data on the local contest winners are derived from the Statistical Office of the Slovak Republic (abbreviated as SOSR, SOSR 2025).

Based on empirical evidence, we constructed the following equation for the determinant "gender of elected political authority":

$$Tax\ revenues_{i,t} \quad = \alpha + \beta_1 * gender + + \beta_{i,t} \sum_{j=1}^{m} X_{i,t} + u_{i,t} \qquad (5)$$

Table 1. Variable characteristics

Variable	Characteristics	Source
Dependent variables		
Local Tax Revenue 100 pc	Total local tax revenue (revenue group 100) per capita in EUR (logs used).	MF SR SO SR
Local Tax Revenue 110pc	Local tax revenue (revenue group 110 containing portion oi personal income tax that is shared tax) per capita in EUR (logs used).	MF SR SO SR
Local Tax Revenue 120pc	Total local tax revenue (revenue group 120 containing immovable property taxes) per capita in EUR (logs used).	MF SR SO SR
Local Tax Revenue 130pc	Own local tax revenue (revenue group 130 containing other local taxes) per capita in EUR (logs used).	MF SR SO SR
Local Tax Revenue 120 and 130 pc	Total own local tax revenue (revenue group 120+130) per capita in EUR (logs used).	MF SR SO SR
Independent variables		
Woman Mayor	Dummy variable, 1 if a woman is elected as the mayor, otherwise 0	Own based on SO SR
Control variables		
Ageing Index	Number of persons in the post-productive age (65 years and older) to the number of people in the pre-productive age (0-14 years) in %.	SO SR
Population	Total municipal population on January 1st.	SO SR
Moving in	Number of persons moving in the municipality (logs used).	SO SR
Unemployed Persons	Number of registered unemployed persons in the municipality (logs used).	SO SR
Debt Service	Sum of principal and interest payments in EUR (logs used).	MF SR
Current Expenditure	Share of current local expenditure on total local expenditure, in %.	MF SR

Notes: Variables in per capita terms are computed using the total municipal population on January 1st derived from the SO SR.
Source: own processing

Control variables involved in the estimations include socio-economic, demographic, and fiscal variables available at the municipality´s level. The available literature on local tax revenue determinants inspires their choice. Population size is one of the most frequently considered tax revenue determinants (e.g., Allers et al., 2001; Cuadrado-Ballesteros et al., 2014; Hanum & Permata Sari, 2022). The economic conditions of municipalities are evaluated using the unemployment indicator (unemployed people), ageing index, and moving in population (see, e.g., Choi et al., 2010; Cuadrado-Ballesteros et al., 2014). From fiscal variables, it is a debt service related to fiscal stress (Buettner & Wildasin, 2006). Local current expenditure as a fiscal variable is interlinked with local tax revenues when municipalities can cover current local expenditures only with current local revenues (Act no. 583/2004 Coll. on Local government budgetary rules). Socio-economic variables are collected from SOSR (2025), and fiscal variables are collected from MFSR (2025).

Table 1 lists the variables, their characteristics, and data sources. Table 2 displays the descriptive statistics using observations 1:01 - 2926:20.

3. Results

3.1 Stylized facts

Among the EU countries, when considering women´s representation in local politics, Slovakia exhibits values above the EU average (see Figure 1) in both cases: women mayors and women councillors. The highest values of women´s representation in local politics in 2024 are evidenced in Finland, Sweden, and the Netherlands in the case of women mayors. In the case of women councillors, the highest representation is in Sweden and Finland, accompanied by Spain and France (see Figure 1).

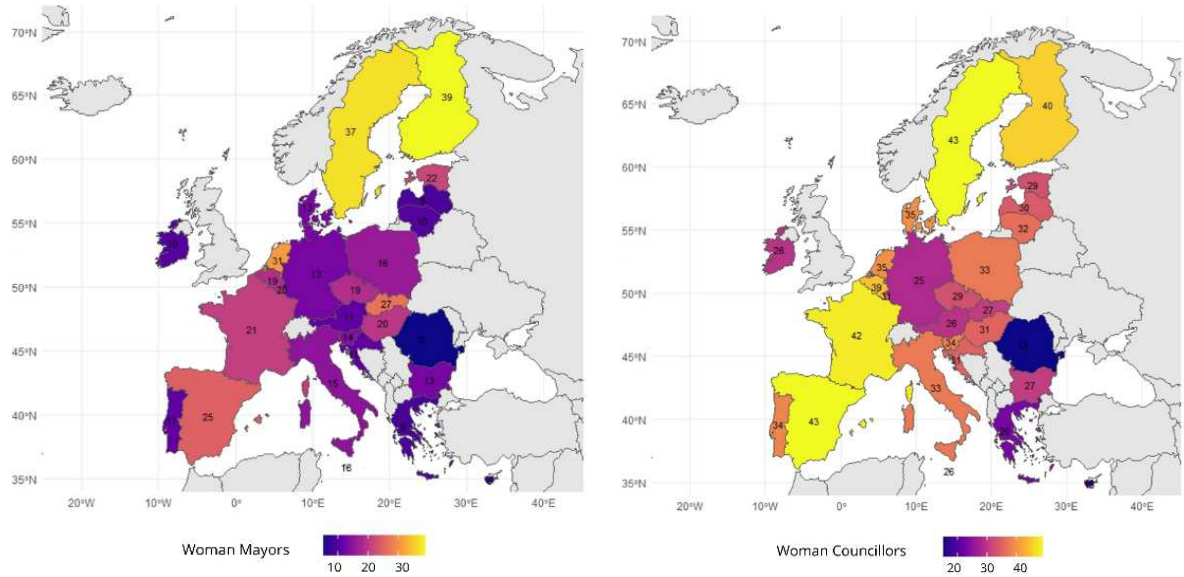

Figure 1. Women mayors and councillors in the European Union (year 2024 displayed, in %)
Source: own processing based on European Institute for Gender Equality (EIGE, 2025)

After the 2022 elections, women mayors represent 26.01% of all mayors (our database is unbalanced, considering only the results of the first election round, this might cause the difference between the EIGE´s statistics and ours). Compared to the year 2002, the increase of 7% is evidenced in the Slovak local public sector. This increase seems to be stable, as it exhibits 19.31% in 2002, 20.23% in 2006, 21.29% in 2010, 22.83% in 2014, 24.78% in 2018, and 26.01% in 2022 (Lukáčová & Maličká, 2023). However, the growth rate of the share of women mayors decreased between 2018 and 2022. Moreover, the most numerous size categories with elected female political authorities in the Slovak Republic are still those with a low number of inhabitants, i.e., size category 1 (up to 199 inhabitants), size category 2 (200–499 inhabitants), size category 3 (500–999 inhabitants), and size category 4 (1,000–1,999 inhabitants). This analysis once again confirms the presence of a fragmented settlement structure in the Slovak Republic, characterized by many small local governments with a low population (Lukáčová & Maličká, 2023). Figure 2 compares the years 2002 and 2022. The increase of 7% is evidenced in the share of elected local political authorities of the female gender in the past 20 years.

3.2 Regression analysis results

The regression analysis is conducted for five models, where the dependent variable is alternated according to the category of local tax revenues, comprising the local total tax revenues and its specific parts. The explanatory, independent variable in each model is a dummy variable for the mayor's gender. In all cases, the FEM and REM were estimated. Based on the Hausman test, Table 3 shows the final estimation results. All models are adjusted by the HAC (Heteroskedasticity and Autocorrelation Consistent Standard Errors).

Table 3. Estimation results

Dependent variable	Local Tax Revenue 100 pc (log)		Local Tax Revenue 110 pc (log)		Local Tax Revenue 120 pc (log)		Local Tax Revenue 130 pc (log)		Local Tax Revenue 120+130 pc (log)

The estimation results show a positive relationship between the women mayor variable and local tax revenue in all estimations (see Table 3). This confirms our expectations, and our findings are in line with those of Slegten et al. (2019), Casarico et al. (2022), and Avellaneda et al. (2022).

When considering the effects of control variables, the variable on population predominantly exhibits a positive, statistically significant beta estimate that corresponds to findings of Allers et al. (2001), and Hanum and Permata (2022), when a larger population presents more taxpayers. The relationship between local current expenditure and local tax revenues in all models is positive and statistically significant. In line with the legal requirements of the Act no. 583 on Local governments budgetary rules, the increase in current expenditure must be covered by the increase in current revenue, thus creating pressure on local tax revenues, which create a dominant part of local budgets. In a similar vein, the relation between the debt service and local tax revenues is positive and statistically significant. The municipality's financial health could be achieved when current local revenues cover interest and principal payments, and indebtedness is solved by capital budget operations only exceptionally, best ever. The positive relationship between the Ageing index and local tax revenues is observed, which points to tailored public policies to address the problem of an ageing population by several financial supports and inter-governmental fiscal equalization performed using the shared taxes in line with findings of Valkana and Oulasvirta (2021). The variable on local unemployment is in a negative, statistically significant relationship with local tax revenues. It points to the decrease in personal income taxes in times of higher unemployment rates, which are via several vertical fiscal equalization schemes shifted to local budgets. Another point of view is the limited possibility of long-term unemployed people to fulfill their obligations, and tax rates in underdeveloped areas are usually lower. The relationship between the moving-in persons and tax revenues is negative, opposite to the findings of Choi et al. (2010) and Cuadrado-Ballesteros et al. (2014). In this case, the structure of immigrants might play a role when collecting the local taxes, as discussed in Hansen, Schultz, and Tranaes (2017).

4. Discussion

The results of our models, as well as those of several international authors (Slegten et al., 2019; Casarico et al., 2022; Avellaneda et al., 2022), confirmed an increase in municipal revenues in periods

when female elected representatives manage local governments. The percentage of women in local politics in Spain also influences variations in municipal expenditures and revenues (Cuadrado-Ballesteros et al., 2021). Similarly, Balaguer-Coll and Ivanova-Toneva (2021) confirmed that female leadership in local governments contributes to improving their financial sustainability and budgetary stability, which is directly related to the revenue performance of municipalities.

The positive impact of female political representatives in leadership positions of local governments in the Slovak Republic was also confirmed by the results of the econometric estimations. We examined the effect of the gender of elected political authorities on the individual categories of tax revenues of Slovak local governments. The model results clearly demonstrated a positive and significant impact of women on the tax revenues of Slovak local governments across all analysed categories of tax revenues (Table 3). The results regarding the control variables are consistent with empirical findings. Despite the insufficient analysis of this determinant in the context of the Slovak Republic, Maškarinec and Klimovský (2017) confirmed the contribution of female mayors in several areas of public life within Slovak local governments.

The results of this determinant within our analysis also confirm the broader empirical evidence pointing to the positive impact of women in local politics. Some studies have shown that women in public office tend to prioritise more transparent and prompt governance, not only during times of crisis (Funk, 2020). This increases citizens' trust in public administration, leading to greater willingness to pay taxes, ultimately resulting in higher tax revenues (Funk, 2020). Female elected representatives also demonstrate different political priorities than their male counterparts, including a stronger emphasis on social expenditures, education, and healthcare.

The financing of these areas of public services may require a more efficient use of existing tax revenues or the introduction of new tax measures, which can increase overall tax revenues while also raising the share of specific categories of tax revenues within total tax income (Alberti et al., 2021; Barnes et al., 2020; Funk & Philips, 2019).

In addition, some studies also confirm that the presence of women in public office may be associated with lower levels of corruption. Brollo and Troiano (2016) demonstrated that, at the Brazilian local level, the likelihood of corruption is 29 to 35 percent lower in municipalities with female mayors compared to those with male mayors. Since corruption often reduces the efficiency of tax collection, its reduction can lead to higher tax revenues. However, in the context of the Slovak Republic, this area is difficult to quantify, as it involves conduct in which an individual abuses their position or function in public administration, and political representatives face potential penalties such as long-term imprisonment, disqualification from office, financial sanctions, or confiscation of assets obtained through criminal activity.

Conclusion

The world gender literature evidences several contributions of females in local and national politics, when there is a plethora of studies on the effect of women political leaders on local fiscal outcomes such as indebtedness, fiscal discipline, social expenditures, corruption, public procurement outcomes, or saving, including the field of taxation, too. In the Slovak conditions, the literature underexplores gender determinants of local fiscal outcomes, even though the increase of female local elected authorities in Slovakia in the last decades is evidenced, and the differences in gendered leadership are well-known and examined in the gender literature worldwide.

In this analysis, we examine the relationship between the gender of the elected political authority and the level of tax revenues of local governments in the Slovak Republic. The results of regression analyses on the sample of all 2,926 Slovak municipalities from 2005 to 2024 showed a positive effect of women mayors on local tax revenues and their categories, in line with the expectations based on the literature review.

However, the gap in this kind of scientific literature in Slovak conditions is also evident when considering other fiscal outcomes, except for a limited number of studies focusing on indebtedness. Thus, further research might focus on several aspects of gendered local budgeting and decision-making. Besides, the research limitations are present because of the different types of Slovak municipalities when classifying them from the point of size measured by their population. The fragmented residential structure of the Slovak local sector, meaning a lot of small-sized municipalities, is widely discussed. The related research, combined with gender literature, stresses women´s

representation in a mayoral position in small municipalities with limited possibilities to drive local development through tailored local tax policies.

The Analysis of Key Indicators of Europe's Digital Transformation

***Mária* Matijová**[1,*] **and *Beáta* Šofranková**[1]

[1] University of Prešov in Prešov, Department of Finance, Accounting and Mathematical Methods, Faculty of Management and Business, Konstantinova 16, 080 01 Prešov, Slovakia

Abstract

Research background: Digital transformation is one of the strategic priorities of the European Union, as it significantly affects economic growth, innovation, competitiveness, and societal resilience. To assess progress in this domain, global composite indices such as the Network Readiness Index (NRI) have been increasingly used to evaluate countries' technological capabilities, governance quality, and digital impact.
Purpose of the article: The aim of this article is to identify the key indicators of digital transformation in selected European Union countries, reveal their impact on GDP per capita, and provide recommendations for improving digital transformation, readiness, and competitiveness of the analyzed countries.
Methods: The study applies quantitative correlation analysis (Kendall's tau) to examine the statistical relationships between the NRI score, its pillars and sub-pillars, and GDP per capita. The analysis is based on secondary data from the Network Readiness Index (2022–2024) and macroeconomic data provided by the World Bank.
Findings & Value added: The results confirm strong and statistically significant correlations between the overall NRI score and its main pillars and sub-pillars particularly in the areas of technological infrastructure, governance, and economic impact. Furthermore, GDP per capita shows a positive relationship with the overall NRI score and selected digital performance indicators, underlining the role of economic strength in supporting digital development. The contribution identifies notable disparities among countries and emphasizes the importance of strategic investment in digital infrastructure, digital skills, and institutional capacity to foster inclusive and sustainable digital transformation in Europe.

Keywords: Network Readines Index, GDP per capita, European countries, Correlation analysis

JEL classification: O11, O33, O52, O57

1. Introduction

Digital transformation contributes to company performance through the implementation of digital technologies, innovations in business models, and changes in value creation. Supporting the development of digital infrastructure and promoting markets with a skilled workforce is essential; therefore, countries and governments that adopt resilience and antifragility measures aim to enhance digital readiness. Digital transformation can be supported by strengthening digital literacy programs, providing financial incentives for digital upgrades, and establishing digital hubs to facilitate the digital transition and digital preparedness of countries (Mátyus et al., 2025).

Digital readiness is defined by Dutta et al. (2023) as the ability to effectively utilize modern technologies to achieve goals and enhance performance, which is becoming a key factor in the innovation process. This complex process includes not only technological infrastructure but also organizational changes, and the ability and skills of employees to adapt to dynamic global markets. An increasing number of researchers and institutions emphasize the importance of digital infrastructure, innovation ecosystems, and AI readiness as determining factors in supporting economic and social performance (IMD, 2023).

[*] Corresponding author: maria.matijova@unipo.sk

The digital economy has become a widely studied topic as the world transitions to digital technologies (Skvarciany et al., 2023). Digital technologies present challenges for entities operating in both global and national markets, transforming how businesses and institutions strategically plan and organize, reduce costs, and develop new types of products and business models on an international scale.

The contribution focuses on assessing the digital readiness of selected EU countries and examining how the Network Readiness Index (NRI) influences the economic performance of these countries.

1.1 Digital transformation

Digital transformation represents a vital component of the digital revolution and a prerequisite for ensuring the competitiveness of economies. The literature offers a wide range of definitions of digital transformation. Papathomas and Konteos (2023) and Teng et al. (2022) define digital transformation as the process of using (emerging) digital technologies to meet customer needs and enhance business empowerment. Fuentes et al. (2024), Ubiparipović et al. (2023), and Korachi and Bounabat (2020) perceive digital transformation as a process involving a comprehensive reconsideration of organizational strategies and structures. Another group of authors describes digital transformation as a process that initiates fundamental changes in a company's organizational characteristics and reconstructs its organizational structure, behavior, and operating systems through the combined use of information technology (IT), computing, communication, and connectivity technologies (Nazari & Musilek, 2023; Teng et al., 2022). According to Czakon et al. (2024), Li & Fei (2023), and Dąbrowska et al. (2022), effective digital transformation requires profound socio-economic change that affects multiple levels including individuals, organizations, ecosystems, and ultimately entire societies.

Traditional firms with established organizational structures and processes face the challenge of digital transformation to a significant extent. A large number of companies consider digital transformation to be the use of new digital technologies to enable significant business improvements, enhance customer experience, streamline operations, or create new business models (Furr et al., 2022). Some economic entities perceive digital transformation as a set of new strategies and business models facilitated by a multitude of emerging information technologies. Views on digital transformation vary, with some institutions and firms regarding it as a straightforward process that improves performance, while many others see it as complex and fraught with challenges (Kane et al., 2021).

Digital transformation involves not only the implementation of digital technologies but primarily changes in established business practices and processes that help companies compete in the digital world (Kane et al., 2021). Its implementation requires new sets of capabilities that enable not only organizational changes but also new processes to leverage digital technologies in order to maximize firm value (Matarazzo et al., 2021). Existing research highlights that although technology is a vital part of digital transformation, it is not the sole area of focus (Hanelt et al., 2021). Talent management, corporate culture, strategy, leadership, and organizational structure play key roles in the digitalization of companies (Elia et al., 2024).

Grimpe et al. (2023) emphasize the importance of providing opportunities in the field of digital knowledge to maintain digital human resources. Digital transformation and innovation (Dong & Verhoef, 2024) have fundamentally changed consumer expectations and behavior, placed pressure on established companies, and disrupted various markets. The main exogenous drivers of digital transformation and business model innovation are considered to be: digital technologies, digital competition, and the behavior of digital consumers. According to Proksch et al. (2021), digital technologies are the main driving force behind digital transformation, yet they require a skilled workforce. The implementation of digital technologies influences most socio-economic and economic processes and activities, from agriculture to public services (Volkova et al., 2021). According to Vasyltsiv et al. (2022), the digital economy requires effective government regulation and support, with mechanisms and tools that evolve in accordance with the current conditions of the digitalization environment through the identification of appropriate incentives.

The necessity of implementing digital technologies depends on a nation's technological infrastructure, such as access to mobile phones, wireless networks, and broadband connectivity—

collectively known as digital infrastructure (Andrews et al., 2018). This infrastructure varies significantly both across and within countries. Weaknesses in traditional infrastructure create opportunities for digital service providers to bridge existing digital divides and support economic development (Kumar et al., 2021; Pelletier et al., 2024).

As a result of these disparities, the ways in which companies use digital technologies to deliver digital products and services differ across countries, influencing their digital readiness in terms of infrastructure, innovation, and technological availability.

1.2 Digital readiness

ICT is often regarded as the most remarkable advancement of the 20th century and is considered one of the key drivers of development, particularly economic growth, in human societies. The use of ICT requires a reliable infrastructure capable of handling the rapidly increasing number of users transitioning to the online environment.

In efforts to enhance digital readiness and competitiveness, the following factors play a crucial role: innovative support for socio-economic indicators in the field of human capital through digital education at all levels, the use of digital skills in the digital labor market and workforce, the development of digital infrastructure across various sectors of the economy, and the promotion of investment in digital technologies and digital innovation in research and development (R&D) for e-business and e-society (Kiseľáková et al., 2024). Digital infrastructure, AI readiness, and digital quality represent key determinants that significantly influence the level of competitiveness (Košiková & Maťovčíková, 2024).

According to Vasyltsiv et al. (2022), digital readiness refers to the widespread adoption of digital technologies in economic and public structures, which determines GDP growth. The authors also confirm that digital readiness is becoming one of the key drivers of national competitiveness. Otola & Knop (2023) emphasize the significant impact of the Network Readiness Index (NRI) on the development of e-Government, transparency, and the formulation of public administration strategies.

Digital readiness and transformation are strategic in nature; however, there is a growing need to strike a balance between technological advancement and the digital literacy of the population (Sulistyanto et al., 2025). Access to and the use of ICT supports sustainable development in all countries, but it is essential for nations to bridge the digital divide in order to fully benefit from sustainable development (Alhassan & Adam, 2024).

1.3 Network Readiness Index (NRI)

The Network Readiness Index (NRI) is used to measure countries' capacities to leverage opportunities offered by ICT and to assess their level of digital readiness. The NRI is one of the most significant indicators reflecting the digital development of nations, providing a much broader view of global digital preparedness (Bánhidi & Dobos, 2024). It is a composite index designed to capture the multifaceted impact of ICT on society and development.

Within the framework of the Network Readiness Index, countries are assessed in terms of infrastructure, innovation, and technology availability. It is a holistic framework that measures the impact of ICT across four key dimensions of society: technology, people, governance, and impact. Its aim is to integrate people with technology in a way that enhances the effectiveness of government strategies for the economy, society, and the environment, making it a reliable tool for measuring a country's e-readiness (Dutta & Lanvin, 2023).

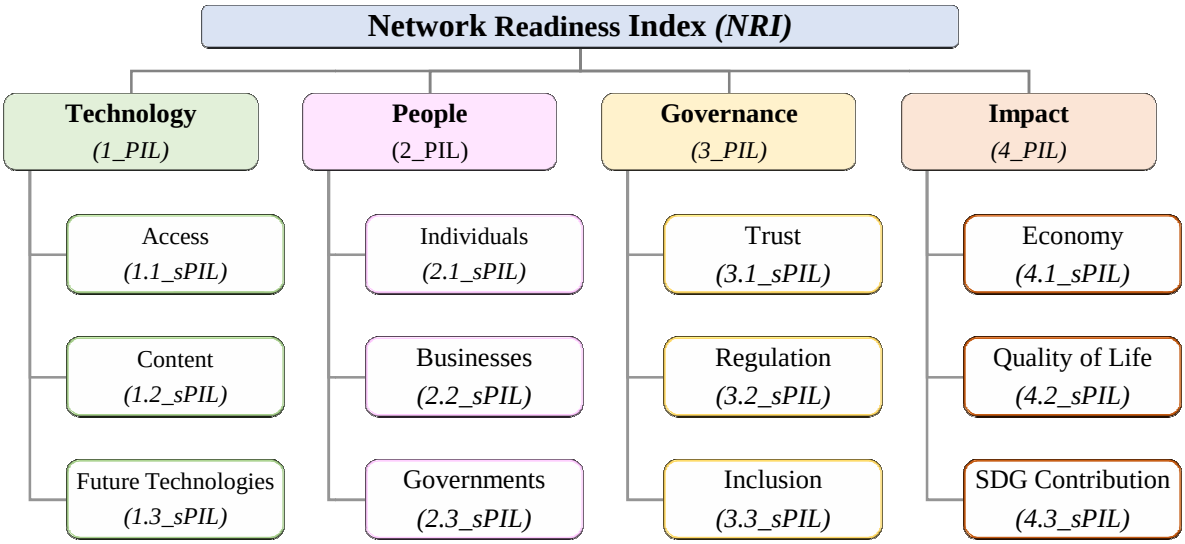

Figure 1. NRI Model of 2024
Source: own processing by Dutta & Lanvin (2024)

As noted by Tokmargenova & Dobos (2024), the NRI index determines a country's readiness for the digital economy. The aim of this index is to evaluate the progress of a country's economy in terms of adopting digital technologies that enhance competitiveness and the well-being of its citizens. The NRI also highlights specific factors that influence the development of the digital economy within a country.

From a structural perspective, the NRI index consists of four pillars, each comprising three sub-pillars. A total of 58 indicators are included in the assessment, although this number was reduced to 54 in 2024.

2. Methods

The aim of this article is to identify the key indicators of digital transformation in selected European Union countries, reveal their impact on GDP per capita, and provide recommendations for improving digital transformation, readiness, and competitiveness of the analyzed countries.

To assess digital transformation, we selected the Network Readiness Index (NRI) for the period 2022 to 2024, and the research analysis includes 40 European countries.

The NRI index evaluates more than 130 countries, with the number continuously changing over time. In 2022, a total of 131 countries were assessed; this number increased to 134 in the following year and slightly decreased to 133 economies worldwide in 2024. From this global set, we focused on European countries and selected 40 of them for our analysis.

The main objective was achieved through the following partial goals:

- *Partial objective 1* → To evaluate the development of digital transformation in the EU-40 countries using the overall score the Network Readiness Index (NRI) for the period 2022–2024,
- *Partial objective 2* → To identify the existence of mutual influences between the overall NRI score and its pillars, sub-pillars, and input indicators,
- *Partial objective 3* → To identify the existence of mutual influences between GDP per capita and selected indicators of the NRI index (overall score, pillar scores, sub-pillar scores, and input indicators).

In accordance with the defined partial research objectives (2 and 3), the following research hypotheses were formulated. Their purpose is to verify the existence of statistically significant relationships between selected variables. The hypotheses will be tested using correlation analysis.

- *Research Hypothesis H1*: There is a statistically significant relationship between the overall NRI index score and its pillars, sub-pillars, and input indicators;

- *Research Hypothesis H2*: There is a statistically significant relationship between GDP per capita and selected indicators of the NRI index.

Interpretation of the correlation coefficient is a frequent problem because there are no generally valid limits. Based on the achieved absolute value of the correlation coefficient, Chajdiak (2013) defined the following 3 degrees of strength of mutual dependence: low dependence (0.10-0.39), medium dependence (0.40-0.79) and higher dependence (0.80-1.00). This scale was used to interpret the results of the correlation analysis.

To test the research hypotheses, the non-parametric Kendall Tau correlation test was employed. The selection of this coefficient was based on the results of normality tests (Kolmogorov–Smirnov test, Lilliefors test, and Shapiro–Wilk test), which indicated a violation of the normality assumption for certain variables within the secondary dataset of the NRI index.

3. Results

In the following section of our contribution, we focus on assessing the development of digital transformation in the EU-40 countries using the Network Readiness Index (NRI) for the years 2022 to 2024, with an emphasis on the evolution of the overall score.

The 2024 edition of the Network Readiness Index (NRI) ranking is dominated by countries characterized by a high level of digitalization, economic advancement, and effective public administration. For the third consecutive year, the United States remains at the top of the ranking, followed by Singapore and Finland, both of which consistently hold positions within the top three. Notable improvements were observed in Sweden and the Republic of Korea, which advanced to fourth and fifth place, respectively. The remaining top 10 positions are primarily occupied by European countries, including the Netherlands, Switzerland, the United Kingdom, Germany, and Denmark. The regional composition of the top ten highlights Europe's dominance, with seven countries represented in the elite group. The Asian region is represented by only two countries (Singapore and the Republic of Korea) while the Americas are solely represented by the United States. This distribution underscores the persistent disparities in digital readiness across global regions and emphasizes the importance of systematically developing digital capacities as a key component of national competitiveness.

3.1 Development of the NRI in the analyzed European countries from 2022 to 2024

The following Table 1 provides an overview of the overall NRI scores of the analyzed countries for the years 2022 to 2024, along with their rankings among the 40 European countries included in the analysis.

Table 1. Evolution of NRI Scores in EU-40 Countries from 2022 to 2024

Country	NRI_2022	RANK	NRI_2023	RANK	NRI_2024	RANK
Albania	46.50	39.	44.98	39.	44.67	39.
Austria	71.31	11.	69.13	10.	66.05	12.
Bosnia and Herzegovina	42.67	40.	40.06	40.	43.20	40.
Belgium	70.04	13.	67.02	13.	65.88	13.

Source: own processing

The average NRI score for the 40 analyzed European countries showed a declining trend during the observed period. In 2022, the average reached 63.50. In 2023, it decreased to 60.98, representing a drop of approximately 4%, and in 2024, the average slightly declined further to 60.60.

In 2022, Sweden ranked first in the European index with a score of 78.91, followed by the Netherlands (78.82) and Switzerland (78.45). The top ten also included Denmark, Finland, Germany, Norway, the United Kingdom, France, and Luxembourg, reflecting their high level of digital readiness. On the other hand, countries at the bottom of the ranking included Bosnia and Herzegovina (42.67), Albania (46.5), and Georgia (47.14), all located in the Western Balkans.

In 2023, a change occurred at the top of the European ranking. Finland became the new leader with a score of 76.19, ahead of the Netherlands (76.04) and Sweden (75.68). Switzerland, Denmark, Germany, the United Kingdom, France, and the Netherlands remained in the top 10, and Austria joined them for the first time. Most countries experienced a slight decline in their scores. The largest year-on-year decrease was recorded by the Netherlands (−5.98), while Luxembourg, Denmark, and Croatia also dropped by more than four points. The smallest decline was observed in Ukraine (−0.55). Bosnia and Herzegovina (40.06), Albania (44.98), and Georgia (45.25) remained at the bottom.

The year 2024 brought several notable changes. Finland maintained its leading position with a score of 75.76, followed by Sweden (74.99) and the Netherlands (73.94). Estonia significantly improved its score, rising from 66.11 to 67.85, which moved it up to 10th place. Bosnia and Herzegovina, although still in 40th place, recorded the largest year-on-year improvement, gaining +3.14 points. In total, 13 countries experienced an increase in their scores, with the highest recorded in Georgia (+4.05 points). On the contrary, 26 countries saw a decline, with the largest drop in Slovenia (−3.19 points). An interesting observation is that Norway achieved the same score of 69.70 in both 2023 and 2024.

Leaders such as Finland, Sweden, the Netherlands, Switzerland, and Denmark continue to hold strong positions and consistently improve their performance. In contrast, Western Balkan countries, despite slight progress, remain at the bottom of the European ranking.

3.2 Evaluation of correlation analysis results

In the following section of our contribution, we focused on conducting a correlation analysis in order to identify the mutual relationships between the NRI index and its pillars and sub-pillars, as well as with the selected macroeconomic indicator, GDP per capita.

Based on the results of the correlation analysis between the NRI index and its individual pillars and sub-pillars (see Table 2), it can be concluded that most relationships are moderately strong and statistically significant.

Table 2. Results of the correlation analysis at the significance level $p \leq 0.05$ (N=120)

Pair of Variables	Kendall Tau	Z	p-value	Pair of Variables	Kendall Tau	Z	p-value
NRI & 1_PIL	0.8297	13.4371	0.0000	*GDPc & 1_PIL*	0.5947	9.6309	0.0000

Note:
0.1 - 0.39 → low dependence
0.4 - 0.79 → medium dependence
0.8 - 1.00 → higher dependence

Source: own processing

The main pillars (1 to 4) demonstrate moderately strong and statistically significant correlations with the overall NRI score, all exceeding Kendall's Tau values of 0.7. The highest associations were recorded for Pillar 1 – *Technology* ($\tau = 0.8297$) and Pillar 4 – *Impact* ($\tau = 0.8255$), confirming that a country's technological advancement and the tangible effects of digital transformation are closely linked to its digital readiness.

Among the sub-pillars, the strongest relationships with the NRI were found in:

- 1.3_sPIL (*Future Technologies*) → $\tau = 0.7350$,
- 2.3_sPIL (*Governments*) → $\tau = 0.7381$,
- 3.3_sPIL (*Inclusion*) → $\tau = 0.7437$,
- 4.3_sPIL (*SDG Contribution*) → $\tau = 0.7014$.

These results suggest that key drivers of digital readiness include innovation capacity, effective public governance, social inclusion, and the contribution of digital transformation to sustainable development goals.

In contrast, sub-pillar 2.1 (*Individuals*) showed no statistically significant relationship with the NRI ($\tau = 0.0616$; $p = 0.3183$), indicating that the level of digital access and engagement among individuals as currently measured may not directly influence the overall readiness score.

In conclusion, a country's digital performance is most influenced by its future-oriented technological infrastructure, institutional quality, and digital impact. Meanwhile, certain aspects of individual-level inclusion appear less connected to national-level digital readiness, highlighting the need to balance structural advancements with inclusive digital policies. These findings support the importance of a multidimensional framework for assessing digital transformation across countries.

In the following correlation analysis, we focused on identifying the mutual relationships between the NRI (overall score, pillar scores, and sub-pillar scores) and GDP per capita of the selected 40 European countries.

Correlation analysis indicates a statistically significant moderate positive relationship between GDP per capita and the NRI (Kendall's Tau = 0.5908; $p < 0.001$), indicating that a higher level of economic development is moderately associated with higher digital readiness in the analyzed European countries. This correlation suggests that countries with higher GDP per capita tend to score

higher on the NRI, indicating that economic prosperity is closely linked to digital readiness. This may be due to better infrastructure, higher investments in technology, and more effective digital governance.

The results of the correlation analysis confirm that there is a positive and statistically significant relationship ($p \leq 0.05$) between GDP per capita (GDPc) and most of the pillars and sub-pillars of the NRI index. The strongest correlation was observed between GDP and Pillar 3 – *Governance* ($\tau = 0.6275$), followed by Pillar 1 – *Technology* ($\tau = 0.5947$) and Pillar 4 – *Impact* ($\tau = 0.5782$). These findings suggest that countries with higher economic performance tend to score better in areas such as regulatory effectiveness, technological innovation, and the measurable impacts of digital transformation.

Among the sub-pillars, the most significant associations were found in:

- 1.3_sPIL (*Futures technologies*) → $\tau = 0.6266$,
- 3.2_sPIL (*Regulation*) → $\tau = 0.6193$,
- 4.3_sPIL (*SDG Contribution*) → $\tau = 0.6014$.

These dimensions exhibit the strongest direct links to a country's level of economic development. In addition, robust correlations were also observed for other indicators such as digital skills, ethical use of technology, and trust in the digital environment, reinforcing the assumption that advanced digital infrastructure and effective governance mechanisms contribute positively to national economic performance.

The only exception was sub-pillar 2.1 (*Individuals*), which showed statistically insignificant correlation ($\tau = -0.0793$; $p = 0.1992$). This implies that the degree of individual digital inclusion is not directly associated with GDP per capita, and in some cases, a slight inverse relationship may exist. Such a result could be attributed to internal digital divides within more economically advanced countries.

3.3 Evaluation of Research Hypotheses

Based on the results of Kendall's correlation analysis, *hypothesis H1* was confirmed at the significance level of $p \leq 0.05$. All four main pillars of the index showed a moderate and statistically significant positive correlation with the overall NRI score ($\tau > 0.70$; $p < 0.05$). Most sub-pillars also demonstrated significant correlations. The only exception was sub-pillar 2.1 (*Individuals*), where no statistically significant relationship was found ($\tau = 0.0616$; $p = 0.3183 > 0.05$).

Hypothesis H2 was also confirmed at the significance level of $p \leq 0.05$. The overall NRI score was significantly correlated with GDP per capita ($\tau = 0.5908$; $p < 0,05$). Statistically significant relationships were also confirmed between GDP per capita and several NRI sub-pillars, particularly *Future technologies* (1.3), *Regulation* (3.2), and the *SDG contribution* (4.3). Again, no significant relationship was found for sub-pillar 2.1 (*Individuals*) ($\tau = –0.0793$; $p = 0.1992 > 0.05$).

4. Discussion

The results of the correlation analysis provide valuable insight into the structural interconnectedness ofkey indicators of digital transformation in Europe. The relationships identified between the Network Readiness Index, its main pillars and sub-pillars, and the macroeconomic indicator GDP per capita, reflect the degree to which digital advancement is embedded in the broader socio-economic context of European countries.

A positive and statistically significant correlation between GDPc and the overall NRI ($\tau = 0.5908$; $p < 0.05$) suggests that a country's digital readiness is closely linked to its level of economic development. In other words, economically stronger countries are generally better equipped to leverage the benefits of digital transformation. This supports the hypothesis that digitally advanced countries tend to achieve higher productivity, stronger innovation performance, and more efficient institutions.

At the pillar level, the strongest correlation with GDPc was found for Pillar 3 – *Governance* ($\tau = 0.6275$), followed by Pillar 1 – *Technology* ($\tau = 0.5947$) and Pillar 4 – *Impact* ($\tau = 0.5782$). These results underscore the importance of technological infrastructure and an effective regulatory framework as fundamental elements of digital competitiveness. Among the sub-pillars, the strongest associations were observed for *Future technologies* (1.3), *Regulation* (3.2), and *SDG contribution*

(4.3) – all with correlations exceeding $\tau = 0.60$. These findings confirm that material and institutional foundations of digitalization are strongly related to a country's level of economic development.

From a social perspective, the results for sub-pillar 2.1 (*Individuals*) are particularly noteworthy, as this dimension showed no statistically significant correlation either with GDP per capita ($\tau = -0.0793$; $p = 0.1992$) or with the overall NRI score ($\tau = 0.0616$; $p = 0.3183$). These findings suggest that the level of individual digital inclusion is not directly determined by a country's economic performance or its overall digital readiness. In other words, a higher GDP does not automatically ensure equal access to digital technologies for all citizens, highlighting the persistence of digital inequality even in economically advanced countries.

In conclusion, digital transformation is a multidimensional process, with technological and economic factors at its core. However, its long-term sustainability depends on the quality of human capital and the level of social inclusion. The key indicators identified in this study thus provide a strong foundation for further monitoring, benchmarking, and targeted digital policymaking across Europe.

Conclusion

An analysis of leading countries reveals a common profile characterized by strong performance across all four pillars of the index: technological advancement, human capital, effective governance of public institutions and positive socio-economic impact. These countries consistently rank within the top twenty to twenty-five in all evaluated dimensions, highlighting their comprehensive readiness for digital transformation.

The key factors of digital transformation identified in this study include technological infrastructure, digital skills, the quality of governance and regulatory environment, and the economic impact of digitalization. These dimensions showed the strongest correlations with both the overall Network Readiness Index (NRI) score and the macroeconomic indicator GDP per capita. In contrast, digital inclusion emerged as a dimension with relatively weaker links to economic performance, highlighting persistent inequalities in access to digital services.

The correlation analysis confirmed a strong and statistically significant relationship between the overall NRI score and most of its pillars and sub-pillars ($\tau > 0.7$; $p < 0.05$). The strongest associations were recorded for technological infrastructure, digital skills, trust and ethics in the digital environment, and the economic impact of digitalization. The only exception was sub-pillar 2.1 (*Individuals*), which did not show a statistically significant relationship with either the NRI or GDP per capita. This finding suggests that social aspects of digital transformation, such as individual digital inclusion, are not necessarily determined by the level of economic development or digital readiness.

The results indicate that countries' economic prosperity is closely tied to their level of digital readiness, with infrastructure, regulation, and the ability to translate digital capacity into real impact playing the most critical roles. On the other hand, social dimensions require specific policy attention, as their connection to economic performance is more complex and not always straightforward. These findings highlight the need for balanced policy-making that, alongside technological and institutional development, also addresses the inclusive nature of digital transformation.

Economic and Political Implications of Public Transport Discount Fares in Czechia

Alex **Mican**[1,*]

[1] Prague University of Economics and Business, Faculty of Economics, Department of Economic and Social Policy, nám. W. Churchilla 1938/4, 130 67 Prague, Czech Republic

Abstract

Research background: Public transport fare discounts serve as a prevalent policy tool aimed at assisting specific demographic groups, fostering social equity, and encouraging sustainable transportation practices. Nevertheless, the economic and political ramifications of these subsidies are frequently overlooked or insufficiently assessed. In the Czech Republic, notable modifications in the scope and regulation of public transport fare discounts took place from 2017 to 2023, particularly impacting students, elderly individuals, and those with disabilities. Although these policies are designed to yield social advantages, they can also impose significant financial strains on public budgets, disrupt competitive dynamics, and affect the quality of services provided.
Purpose of the article: Paper offers a critical examination of the economic justifications, political motivations, and wider socio-economic effects of the public transport discounts enacted in the Czech Republic during the specified timeframe. The objective is to discern both the intended benefits and the unintended repercussions, thereby providing a thorough analysis for policymakers.
Methods: The research utilizes a mixed-methods approach, integrating qualitative policy analysis, structured reviews of legislative documents, and quantitative evaluations of data sourced from several Czech ministries, Czech Railways, and Flixbus CZ s.r.o. as a private operator of bus public transportation. A systematic analysis of comparative statistics and economic indicators, including budgetary expenditures, and market share distributions, was conducted.
Findings & Value added: Findings reveal that fare discounts have led to a significant increase in fiscal expenditures and contributed to market distortions that favor state-owned operators over private competitors. This study contributes to the discourse by identifying policy inefficiencies and proposing alternative strategies for more economically viable and socially equitable transport subsidies.

Keywords: Fare discounts, Third-degree price discrimination, Czech Republic, České dráhy, a.s., FlixBus CZ s.r.o.

1. Introduction

In contemporary society, various forms of discounts can be observed as both social and commercial constructs across a wide range of economic sectors. These discounts are prevalent in specialized retail outlets, subsidized public transportation fares, and online retailers operating on both national and international levels. The rationale behind these financial incentives is rooted in the classification of the economically inactive demographic, which includes pensioners and students, and their associated productivity levels. Despite their potential contribution to the economy as future labor market participants or active contributors to the silver economy, their current status represents a financial burden rather than a source of revenue for the state. Alongside younger minors and individuals with health challenges, they comprise what is referred to as the unproductive segment of the population, which typically benefits from discounts as well as other socio-political initiatives or state subsidies. According to the Czech Statistical Office, in 2023, there were nearly 1,730,000

* Corresponding author: mica03@vse.cz

individuals under the age of 15 and over 2,230,000 aged 65 and above in the Czech Republic. Additionally, there were 484,758 secondary school students and 308,640 university students enrolled. Furthermore, over 1.1 million individuals with disabilities were documented. Collectively, these groups represent a substantial portion of the Czech populace, accounting for over 43%. Due to their prolonged economic inactivity, they are frequently monitored by authorities overseeing social policy, as they are recipients of various benefits, including reduced prices for goods and services. This approach is not solely a governmental initiative but also a common strategy employed by retailers to attract new customers and enhance their market competitiveness. Public transportation systems are similarly influenced, with financial support directed towards the aforementioned demographic groups.

This article seeks to examine the discounts implemented in public passenger transportation and their effects on the extent and quality of services provided by specific carriers, as well as the broader economic context of the Czech Republic. A comprehensive analysis will focus on the state railway operator České dráhy, a.s., and the private bus service Flixbus CZ s.r.o. during the timeframe from 2017 to 2023, particularly highlighting the period from September 1, 2018, to March 31, 2022, when a nationwide discount of 75% on fares was applicable for children aged 6 and above, students up to 26 years, and seniors aged 65 and older.

1.1 Discount as a form of price discrimination

Various prices are assigned to distinct categories of goods, diverse consumers, and different consumer groups. This situation exemplifies price discrimination, driven by the aim to achieve greater economic profit alongside consumer surplus (Bergemann et al., 2021).

For price discrimination to be effective, three essential conditions must be met. Firstly, the firm needs to identify at least two market segments or consumer groups. Typically, these segments vary in terms of income levels, which sellers can discern. Additionally, customer groups exhibit differing demands, which tend to decrease in an imperfectly competitive market. Lastly, sellers must possess the capability to implement a so-called dual pricing strategy. Economically, this serves as a straightforward method for enhancing revenue and optimizing consumer utility (Jurečka, 2018).

Pigou (1932) identified three levels of price discrimination, which categorize prices based on different consumers (1st degree), varying quantities of goods (2nd degree), and distinct consumer groups (3rd degree), with these categories not being mutually exclusive. The first degree embodies rather an idealized perfection, whereas the third stage, recognized as the most prevalent manifestation of this microeconomic phenomenon, operates effectively under the condition that distinct groups refrain from trading the specified goods amongst themselves, meaning they do not engage in arbitrage. Consequently, sellers can adjust prices based on geographical location while simultaneously providing preferential pricing to wholesale clients. In the new millennium, an alternative classification was introduced, based on compatibility, profitability, and information complexity (Chao, Nahata, 2021). This classification, in descending order, includes total discrimination, direct segmentation, and indirect segmentation (Rabay, Andrade, 2019).

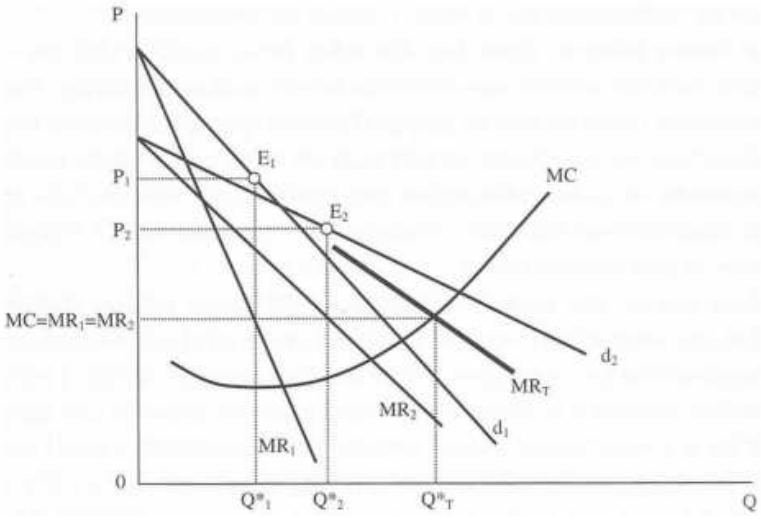

Figure 1. Third-degree price discrimination
Source: Musil (2009)

The studies reviewed primarily investigate the link between third-degree price discrimination and welfare evaluation, questioning its societal benefits or drawbacks. Analysis indicates that social welfare improves for consumers paying lower prices under price discrimination. To enhance overall social welfare[1], aggregate production must increase, thereby strengthening the market. In oligopolistic markets, one segment may operate outside the single price, causing cross- and inter-market consumption externalities (Adachi, 2022). Recent research in platform economics considers these externalities in the context of imperfect competition (Belleflamme, 2021). The differences between traditional third-degree price discrimination in monopolies and its modern interpretation in oligopolies are slight, as both can be analyzed through consumer behavior (Wang et al., 2023). If firms are symmetrical, the graphical analysis applies to both cases. This reasoning can also extend to more heterogeneous inter-firm environments through empirical research (Adams and Williams, 2019). Future theoretical advancements are expected in exploring third-degree price discrimination in imperfectly competitive intermediate markets (Gaudin and Lestage, 2022).

In duopoly markets, price discrimination can enhance competition and benefit consumers. However, if data access or processing technology is uneven, consumers may not gain advantages; instead, sellers and price-sensitive buyers may benefit (Graham, Mulley, 2012). While this may seem efficient, it overlooks consumer living standards, raising issues of social justice and privacy. Allowing data ownership, especially of big data, could reduce incentives for its collection, highlighting the need for alternative data utilization methods beyond price discrimination or advertising (Ezrachi, Stucke, 2016).

1.2 Development of price regulation in domestic public transport in the Czech Republic

In accordance with the Regulation of the Ministry of Finance of the Czech Republic No. 1/2023 (2022) and the statutory authorization specified in Section 10 of Act No. 526/1990 Coll. (Prices Act), there are three categories of price regulations that are applicable in the Czech Republic: maximum prices, objectively guided prices and fixed prices. All categories encompass public transport fares. Although regions and municipalities possess the authority to establish maximum prices, passenger transport that is based on nationally integrated public services is regulated by what are known as fixed prices. These fixed prices enable transportation to the destination station utilizing the services of any public carrier, all based on a single document[2]. Other transported goods are subject to material price guidelines, which, while not legally mandated, are determined through negotiations between sellers and buyers according to established protocols. This material guideline is relevant to both rail and bus public transport.

The price regulation outlined in the Regulation also mandates that carriers provide certain demographic groups with preferential fares that range from 50% to 100% of the standard fare. Each carrier determines these fares individually, following the guidelines and calculations specified in the Regulation. The extent of these discounts, along with their amounts, is monitored by regional and municipal authorities in collaboration with the Specialized Financial Office. This oversight primarily focuses on ensuring the accuracy of price records, the proper application of discounts in line with price regulations, and preventing any misuse of the carrier's economic position. Should any infractions of these regulations be identified, the authorities are empowered to impose fines or implement other corrective actions (Ministry of Finance of Czech Republic, 2022).

The evolution of price regulation in domestic rail and bus transport has been shaped by objective price guidance. This requires carriers to provide discounts to vulnerable passenger groups to ensure their access to public transport. Fare rates have varied due to factors like vehicle purchase prices, fuel costs, excise tax changes, and operational expenses, alongside commercial considerations[3]. A key

1 The group of consumers paying a higher than equilibrium price is defined as a strong market, while consumers paying a lower price as a weak market.

2 Carriers that wish to adhere to the provisions of the uniform tariff system must enter into an access agreement with the system's owner, which is the state, represented by the Ministry of Transport of the Czech Republic.

3 Mandatory discounts on travel fares for pensioners were initially implemented in the Czech Republic in 2001, providing a reduction of 50% off the standard fare for second-class passenger trains, which includes EuroCity and Intercity services. As of September 1, 2004, following Government Resolution No. 624/2003, discounted travel fares were made available for pupils and students attending all educational institutions in the Czech Republic up to the age of 26, who are fulfilling compulsory school attendance or are engaged in full-time studies to prepare for their future careers. Over time, the extent of

example is the government resolution from 27 March 2018, which adjusted discount rates. From 1 September 2018 to 31 March 2022, certain groups (children, students, and pensioners) paid only 25% of the full fare, which increased to 50% on 1 April 2022 as part of consolidation efforts[4]. Additionally, the fare structure transitioned from a zone tariff to a distance-based model, supported by a financial cap from the Ministry of Transport. Recently, a unified tariff system was introduced, allowing travel on a single ticket across multiple railway companies since December 2020.

1.3 The concept of public support and public service provided by the private sector in the quality of public transport

The legal framework for public support is defined by European law[5], with the European Commission determining its compatibility with the internal market. This applies to measures that meet four defining features[6], which, if satisfied, allow for execution without determining the form of public support. The key concern is the impact on competition. Generally, measures meeting all defining features are prohibited unless a legal basis is found that the Commission recognizes as compatible[7]. An exception is small-scale support (de minimis), which does not distort competition or trade among Member States and adheres to financial thresholds. In the transport sector, the satisfaction of all defining features is common, especially for compensating public passenger transport services[8]. If conditions in the Regulation are met, this support is compatible with the internal market without prior Commission evaluation[9]. In the Czech Republic, this framework was amended by Act No. 194/2010 Coll., regarding public passenger transport services.

In general, the support provided by public entities is inherently associated with the development and functioning of transport infrastructure due to its considerable capital intensity. Although the European Union does not explicitly establish any regulations defining infrastructure projects that do not qualify as public support, the European Commission differentiates between initiatives aimed at constructing or enhancing what is referred to as general and specific infrastructure when implementing these regulations (Kekelekis, 2011).

The regulation of public support within the transport sector is marked by a duality of legislation, where the legal framework for evaluating the compatibility of public support with the internal market varies depending on the type of transport being subsidised. In conjunction with the gradual liberalisation of prices since the 1990s, a crucial element of public support in transport is also the liberalisation of markets, which has become prevalent throughout the Union. The extent of this liberalisation differs among various transport types and thus serves as a primary factor influencing the Commission's decision-making processes. The rail transport sector remains the least liberalised among all transport modes. In terms of passenger rail transport, the market has only been opened to international transport, while national transport remains closed. Conversely, in the realm of road

---

discounts has also evolved for various demographic groups, such as individuals with disabilities, members of state authority, war veterans, and political dissidents (Ministry of Finance of the Czech Republic, 2022).

4 The policy regarding discounts for individuals with disabilities (those holding ZTP and ZTP/P cards) remains unchanged. In 2022, the cap on the number of children under the age of 6 who can travel for free was eliminated, and a new discount of 50% off the full fare was introduced for individuals classified as disabled in the 3rd degree. Between April 1 and August 1, 2022, individuals escaping the war in Ukraine were provided free transportation to secure essential documentation.

5 In the primary law of the European Union, the legal definition of public support is contained in Article 107(1) of the Treaty on the Functioning of the European Union (Part Internal Policies and Actions of the Union, Section State Aid).

6 The measure is granted through State resources; The measure is selective and favours certain undertakings or specific production sectors; The measure distorts or threatens to distort competition; The measure affects trade between Member States (Rydelski, 2006).

7 In the cumulative fulfilment of all defining features, the provider of public support is obliged to inform the Commission per Article 108(3) of the Treaty on the Functioning of the European Union.

8 In accordance with Regulation (EC) No 1370/2007 established by the European Parliament and the Council regarding public passenger transport services via rail and road, the primary intervention of this obligation was to provide a clearer legal framework concerning the duration of passenger transport contracts, the process for selecting carriers, and the requirements for information publication. This regulation applies to public services in both national and international passenger transport by road and rail.

9 In accordance with the individual exemption for compatibility with the internal market as outlined in Article 107(3) of the Treaty on the Functioning of the European Union, public support can only be provided following prior approval from the Commission. Specifically, in the realm of public transport, this pertains particularly to those forms of support that align with the coordination of transport or that serve as compensation for specific services associated with the notion of public service (Article 93 of the Treaty on the Functioning of the European Union).

passenger transport, international transport was liberalised as early as the 1990s[10]. The Commission considers the market for urban, suburban, or regional public transport to be competitive, as companies providing transport services are permitted to operate in member states other than their country of origin.

Although the public sector often provides purely private goods at no cost, this is a matter of political choice[11], and the efficiency of delivering these goods tends to be lower. However, private services in public passenger transport, known as the open access regime, have positively impacted the quality of the services offered. In the context of rail transport, this model relies on adequate infrastructure capacity. If the service is to be established on a commercial basis, it may struggle to adequately address the fluctuations in demand during peak times, which can arise from directional asymmetry or inefficient utilization of rolling stock. Consequently, this leads to costs that are not offset by sales, resulting in financial losses. To mitigate this issue, commercial carriers typically provide reserved seating, which helps them manage relatively inconvenient demand during peak periods. For passengers, this necessitates purchasing a seat well in advance, thereby reducing service flexibility and potentially causing a loss of some prospective customers. As a result, numerous public transport frameworks in various countries are exploring relevant enhancements to their current models (Ministry of Transport of the Czech Republic, 2021).

Long-distance bus transport mainly operates commercially on routes lacking quality rail infrastructure, facing significant fluctuations due to competition. Regions struggle to manage these fluctuations, and the Czech Republic does not intervene due to a lack of regulatory tools. Regulation No. 1370/2007 outlines state involvement in public transport, particularly through compensation for losses from mandatory discounts, improving profitability. A key goal of revising the Public Transport Concept is to create new authorities to regulate congested bus routes and better integrate them into long-distance transport. Ensuring quality through rapid bus services is essential, paving the way for a sustainable rapid rail connection and enhancing passenger transport services (Ministry of Transport of the Czech Republic, 2021).

2. Methods

The theoretical framework of this article is grounded in a comprehensive literature review, which includes an analysis of various international studies and professional monographs. The practical component relies on a comparative assessment of publicly accessible data from the companies being examined. Specifically, for both companies compared, the provisions of Act No. 106/1999 Coll. concerning the right to information were utilized. Conversely, the practical section delves into the evaluation of economic metrics and service quality offered by both transport providers from 2017 to 2023, a timeframe during which both entities were active in the public transport sector concurrently, with a particular focus on state compensation and the resulting economic and political ramifications in the Czech Republic.

3. Results

Offering discounts to designated target groups enables carriers to manage the socio-demographic composition of their passengers while also assisting individuals with limited disposable income. This analysis centers on the state-owned railway operator České dráhy, a.s., as well as the private bus service provider FlixBus CZ s.r.o..

10 At present, this refers to Regulation 1073/2009 established by the European Parliament and the Council, which outlines standard regulations for accessing the international market for coach and bus services. This regulation permits, among other provisions, cabotage—defined as national road passenger transport conducted by an entrepreneur who does not reside in the respective Member State—in specific contexts such as regular, occasional, and international regular transport.

11 In this manner, governments tackle scenarios in which discriminatory pricing practices intensify income disparities or serve as a tool of state paternalism, particularly when the consumption of goods yields positive societal impacts. Furthermore, such consumption may be restricted, for instance, through the implementation of a governmental pricing system or by employing specific measures such as quotas or other forms of quantitative limitations (Stejskal et al., 2023).

On March 27, 2018, the government approved a proposal for a 75%[12] fare reduction for youth and seniors, effective September 1, 2018. This initiative faced criticism from experts and the public regarding fund allocation, potential budget cuts in other departments, and concerns about market interference, which may persist regardless of government changes (Tomeš et al., 2018).

Discounts for specific demographics varied significantly, as shown in the table below. Notably, pensioners over 65 received no discount[13]. Before September 1, 2018, pupils and students could access discounts for educational travel during the academic year, excluding summer vacations. After legislative changes, all demographic groups received a standardized 75% discount, except for travelers visiting parents in institutions.

Table 1. Amount of discounts on travel fares for selected population groups in the Czech Republic before and after the introduction of the 75% discount

Discount Category	***Discount until 1.9.2018***	***Discount from 1.9.2018 to 31.3.2022***	***Discount since 1.4.2022***
Children under 6 years old	100 %	100 %	100%
Children from 6 to 15 years old	50 %	75 %	50%
Pupils from 6 to 15 years old	62,5 %	75 %	50%
Students from 15 to 26 years old	25 %	75 %	50%
Pensioners aged 65 years and over	-	75 %	50%
Persons with disabilities	75 %	75 %	75%
Guide for people with disabilities	100 %	100 %	75%
Parental visits to institutions	75 %	50 %	50%

Source: Ministry of Transportation of Czech Republic, own processing (2024)

The increase in discount percentages led to a significant rise in state fare compensation, complicating the financial aspects of the measure. This complexity was supported by bus operators receiving compensation to ensure the public transport network remained cohesive. As a result, the system functioned effectively during simpler times, allowing occasional passengers to benefit from discounts and no entry fees.

On January 1, 2020, the Ministry of Transport began limiting the fare amount used to calculate discounts, which allowed carriers to continue reimbursing 75% of the fare while the Ministry compensated based on kilometers traveled. This change was necessary due to inflated ticket prices. Since fare pricing is at the discretion of each carrier, the state must reimburse carriers for lost revenue from discount regulations, but cannot limit the compensation amount. Therefore, the measure sets a ceiling on the full fare price for discount calculations[14], with compliance monitored by the Specialized Financial Office, which can enforce price controls if needed (Ministry of Finance of Czech Republic, 2019).

12 The initial proposal aimed to provide free rail transport for students and seniors for an annual fee of 1,000 CZK, inspired by a similar initiative in Slovakia that began in 2014. Following the Czech Ministry of Transport's advice, the proposal was revised from a full discount to a 75% discount and expanded to include bus transportation.

13 Until September 1, 2018, a 25% discount was provided to pensioners based on the carriers' own commercial decision (Ministry of Transport of the Czech Republic, 2018).

14 Discounts are deducted from the standard fare that the carrier charges to passengers who do not qualify for the state-mandated discount. Concurrently, the fare amount must not surpass the figure that each carrier determines based on its allowable expenses, and the cost of one ticket cannot be balanced by the cost of another ticket.

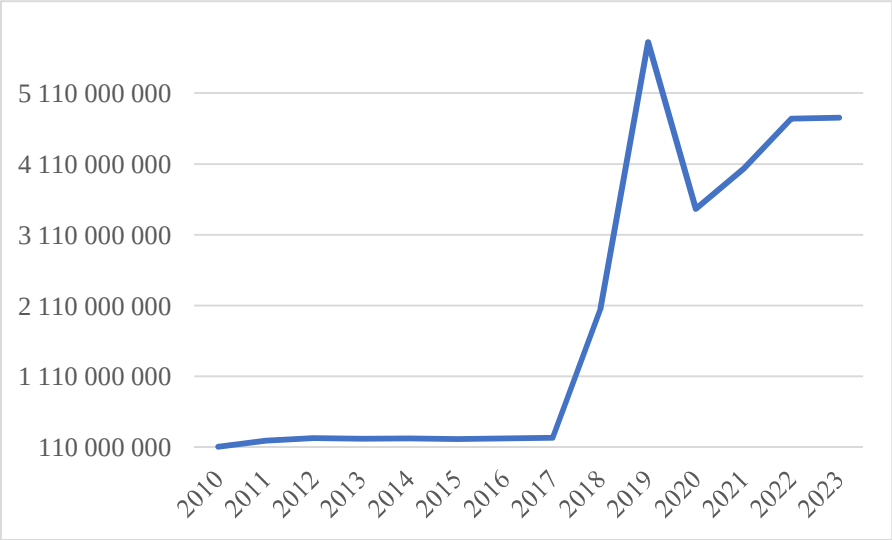

Figure 2. Development of the total amount of compensation provided (in CZK) in public passenger transport in the Czech Republic in 2010 - 2023
Source: Ministry of Transportation of Czech Republic, own processing (2024)

The graph above shows the growth of compensation payments to public transport carriers in the Czech Republic since 2010. A significant increase occurred in 2018 when the state began compensating all carriers, including those in the public sector, whereas previously only commercial route operators received compensation.

On April 1, 2022, the compensation payment structure changed, reducing the discount rate from 75% to 50%[15]. Minister of Transport Martin Kupka stated this was necessary to lower state debt, control inflation, and cut operational costs, while still supporting public transport as a socially responsible and budget-friendly option, preventing a shift back to private car use (Ministry of Transport of the Czech Republic, 2022).

The public sector heavily depends on the state budget for financing and management, affecting discount pricing and operational efficiency based on public finance conditions and fiscal policy changes. A notable example of preferential pricing is public transport fares, which include city subsidies for urban transport and integrated systems funded by European grants, as well as the primary railway operator, České dráhy, a.s. In analyzing České dráhy, it's important to note that long-term profitability for railway operators in Europe is rare, with most funding coming from public subsidies[16]. Historically, governments have influenced railway development and operations, often leading to state ownership (Seideglanz, 2006; Tomeš, Pospíšil 2006), a trend also seen in the Czech Republic.

Czech Railways' revenue primarily comes from three sources: passenger transport income, state or regional subsidies, and leasing of freight wagons. Passenger transport revenue mainly stems from ticket sales for domestic and international travel, with compensation for discounts factored in. The table below shows total ticket sales revenue and compensation from 2017 to 2023. Despite competition and the COVID-19 pandemic, Czech Railways has increased ticket sales revenue annually, surpassing 11 billion Czech crowns in 2023, mainly due to more passengers. Notably, compensation payments have remained below 25% of total revenues over the past eight years, indicating that many passengers likely pay full fare rather than using discounts.

15 Complimentary transportation continued to be provided for children aged 6 and under, along with a prior 75% discount for individuals with disabilities. Furthermore, this year, the discounts have been expanded to encompass individuals with 3rd-degree disabilities.

16 Transport providers depend on state subsidies since fare income does not cover operational costs. Raising fares may lead to customer loss to competitors due to high price elasticity, ultimately reducing overall revenue (Tomeš, Pospíšil, 2005).

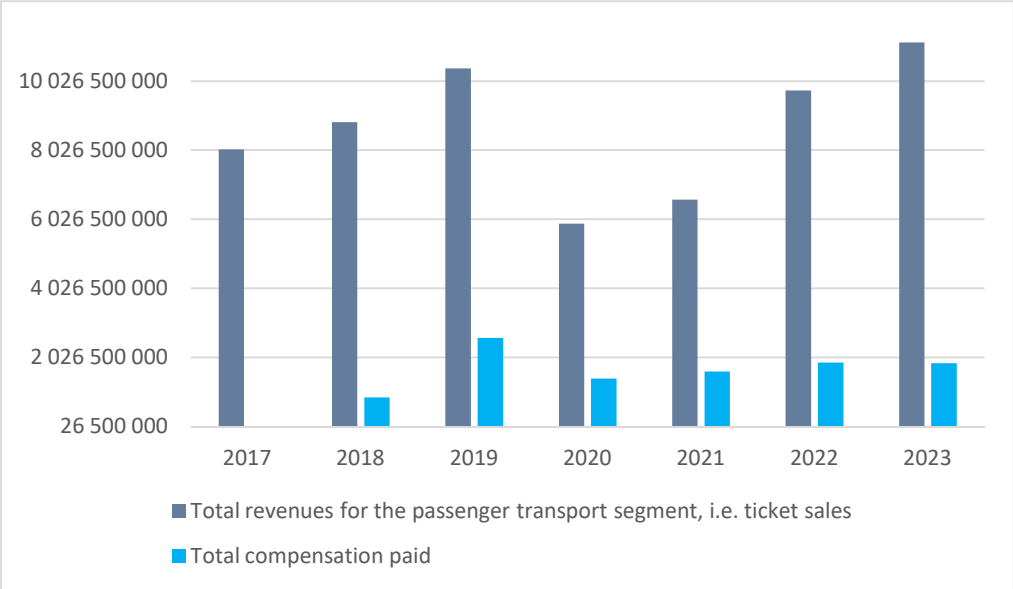

Figure 3. Ratio of total revenues (in CZK) for tickets sold and compensation paid in 2017–2023 for the carrier České dráhy, a.s.
Source: Annual reports of the company, own processing (2024)

Flixbus, s.r.o. offers discounts to specific demographic groups similar to other companies in the industry. Currently, discounts are available for students under 26, children under 17, disability cardholders and their companions, seniors 65 and older, and those with a 3rd degree disability status (flixbus.cz, 2025). From September 1, 2018, to March 31, 2022, these groups received a 75% discount. After state-mandated discounts were reduced on April 1, 2022, Flixbus chose to maintain higher discounts at its own cost to ensure affordable mobility amid rising inflation.

The particular reality of the company lies in its concept of dynamic pricing, which it was the first to implement in the market using relatively sophisticated calculation techniques. This system does not solely rely on the bus's occupancy and the interval between the ticket purchase and the bus's departure. It also takes into account various other factors (such as the days of the week or the influence on the occupancy of alternative routes). Ultimately, the method of purchase is determined by the passenger (Tomeš et al., 2022).

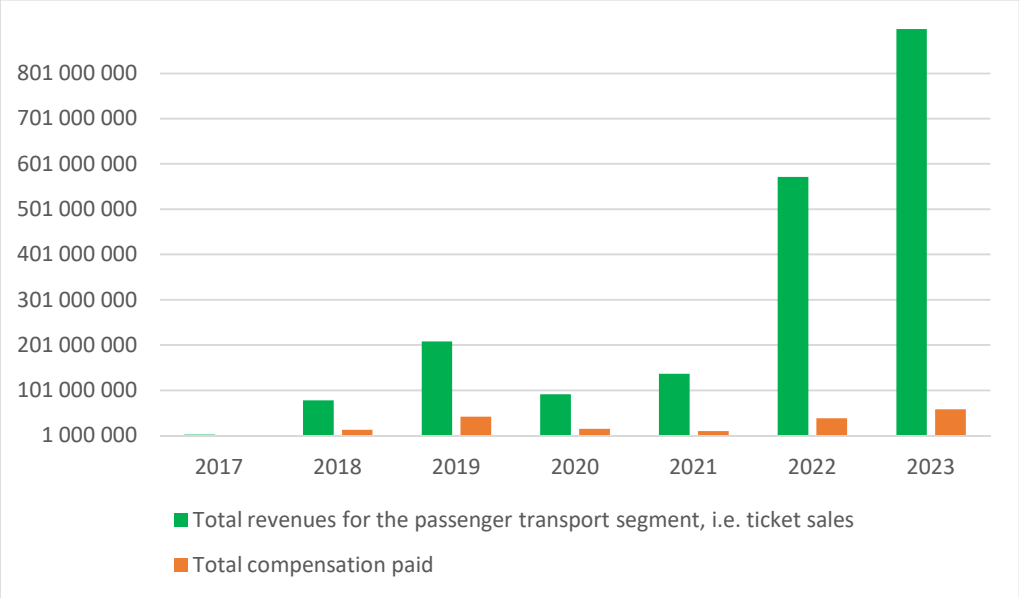

Figure 4. Ratio of total revenues (in CZK) for tickets sold and compensation paid in 2017 - 2023 for the carrier FlixBus CZ s.r.o.
Source: Annual reports of the company, own processing (2024)

Based on the graph presented above, one can infer that there will be a significant surge in ticket sales following the decline of the COVID-19 pandemic, with projections indicating nearly 900 million Czech crowns in sales by 2023. The extent of state compensation provided is particularly noteworthy. Considering the company's extensive operations, particularly in international transport as opposed to domestic transport, and acknowledging that discounts are exclusively available within the Czech Republic, this notable disparity can be understood. Thus, it can be concluded that passengers predominantly utilize the services of FlixBus CZ s.r.o. for international travel, where the aforementioned discounts do not apply. Nevertheless, offering greater discounts than its competitors could yield multiple advantages for the company. Primarily, this strategy could attract a larger segment of price-sensitive customers, fostering long-term loyalty. Furthermore, if the carrier can successfully merge competitive pricing with consistent or enhanced service quality, it may be regarded as both reliable and innovative.

4. Discussion

The fare discounts provided by the state railway and private bus services have significant economic and political effects in the Czech Republic. These effects mainly involve compensation payments, where the state reimburses carriers for losses due to discounts. Since reducing discounts from 75% to 50%, over 1 billion Czech crowns have been saved compared to 2019. About 40% of total compensation goes to Czech Railways, highlighting its strong position in the railway sector. In contrast, private bus operator Flixbus has received only 1% of total compensation since 2017, reflecting the intense market competition.

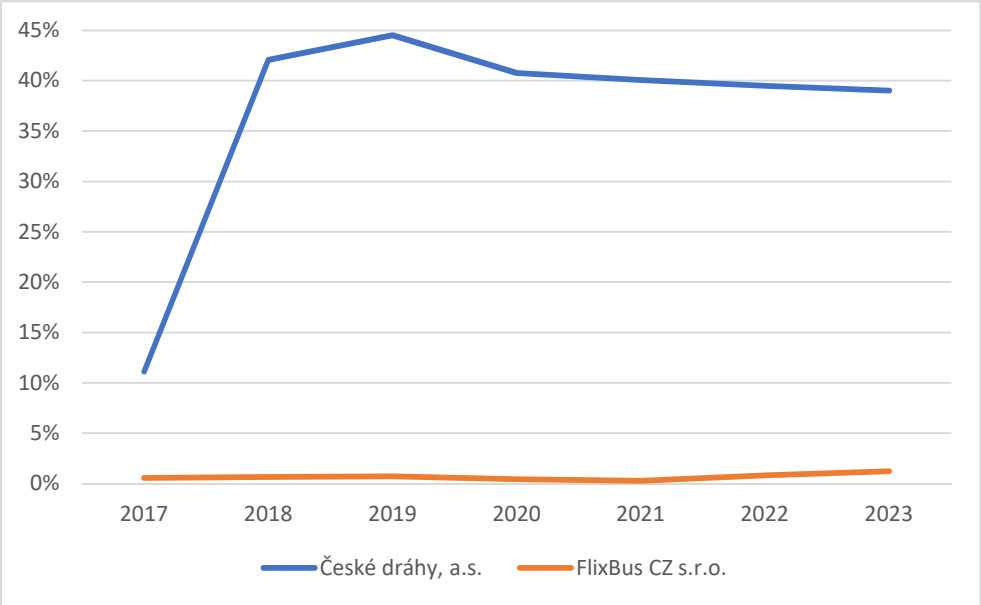

Figure 5. Ratio of compensation paid to České dráhy, a.s. and FlixBus CZ s.r.o. to the total amount of compensation paid in the Czech Republic in 2017 - 2023
Source: Annual reports of the companies, own processing (2024)

The primary concern in this situation is whether the state will cover this expense. Throughout the period of the 75% discounts, the state disbursed more than 14 billion CZK in compensation. It is important to consider that the largest beneficiaries of discounts are students and pensioners. Given their economic or life circumstances, one must question the necessity of such a universal and solidarity-based expenditure. Although pensioners have preserved their purchasing power in recent years, despite volatile economic conditions, students are more likely to encounter qualitative issues, particularly an increase in psychological challenges that subsequently lead to economic difficulties (Henriques et al., 2024). In the Czech Republic, 26% of students have classified their financial issues as serious or very serious. While this figure is not the worst in the current context, a comparison over the last decade reveals that the economic situation for students has worsened the most in the Czech Republic, declining by 12 percentage points (Hauschildt et al., 2024).

The data regarding the number of individuals utilizing public transport does not support the necessity of this expenditure, as it fails to demonstrate a positive correlation with the level of discounts offered. The lack of tax benefits as a corporate incentive is also significant. This incentive applies when companies purchase vehicles for their employees, yet it is not similarly applied to public transport usage. At that time, the Association of Transport Companies also opposed substantial discounts, with its chairman expressing doubt about this expenditure, arguing that passengers should contribute to the costs associated with transportation. Given the state of public finances, the Czech Fiscal Council (2022) also advised the complete elimination of discounts. Consequently, the debate and final decisions have been confined to the realm of high politics.

Conclusion

Discounts are a key part of pricing strategies for both private and public sector companies. They go beyond just quantity or loyalty, reflecting societal values, especially when aimed at specific groups like minors, students, retirees, or those with health issues. This article examines discount pricing and its economic and political effects in the Czech economy, focusing on public transport. It compares the state railway operator, České dráhy, a.s., with the private bus service FlixBus CZ s.r.o. The discussion frames discounts as third-degree price discrimination, where different prices are set for various consumer groups. A future concern is how price discrimination will function in oligopolistic markets and the impact of evolving information technologies on personal data protection. Less productive and more price-sensitive populations lead traders to adjust prices, though price is not the only factor. České dráhy uses fare discounts to promote social policy for accessible public transport, while FlixBus CZ s.r.o. offers significant discounts from its revenues, aiming for a similar strategy.

From an economic and political perspective, personalized discount pricing in the Czech Republic serves as a crucial mechanism not only for businesses but also for the government, which employs it to enhance service accessibility for specific demographic groups. While the discourse among professionals or those deeply engaged in the transport sector tends to be more cautious than bold, political figures approach the issue from a more socially conscious angle, aiming to convey empathy. In the upcoming months, the Czech Republic is poised to experience renewed discussions on this topic in light of the forthcoming parliamentary elections, as political parties seek to solidify and broaden their voter support. Achieving a balanced solution for offering travel fare discounts necessitates a rational examination of the matter. A professional framework, efficient management, and appropriate resource distribution can positively impact both commercial and social policies, potentially generating a synergistic effect that benefits all stakeholders involved.

Abstract

Purpose of the article of the sharing economy in Russia through the prism of coliving. Its impact on social and economic aspects of urban life is assessed, factors contributing to the development of coliving are identified, consumer motivation is studied and a comparative analysis of international experience is conducted. The results of the article can contribute to the development of recommendations for stimulating the economy of shared consumption.
Methods: The qualitative analysis included polystructured interviews with coliving residents, managers, and experts in real estate and social policy. The quantitative analysis was based on the processing of data from open sources and the results of target audience surveys. An important element was the case study method, which allowed us to consider successful and unsuccessful projects and identify key development factors. SWOT analysis was used to comprehensively assess the situation, revealing the strengths and weaknesses of coliving, as well as the opportunities and threats.
Research results we can conclude that motivations of coliving residents range from cost savings to a desire for social integration and exchange of experiences. Successful projects are characterized by flexible management, resident involvement in decision-making, and developed infrastructure, while unsuccessful ones face a lack of funding and a lack of a clear concept. The SWOT analysis noted accessibility and facilitation of community formation as strengths/
Findings & Value added: Coliving contributes to the increase of housing affordability and development of urban communities. Its growth requires flexibility of legislation, support of the authorities and increased public awareness.

Keywords: Sharing economy, Collaborative consumption economy, Co-living, Rent, Resources

JEL classification: O33, P12, O57, M20

1. Introduction

Sharing economy or collaborative consumption economy is an economic model based on the exchange of access to goods and services instead of their traditional ownership purchase. The concept has become possible owing to digital technology development - it simplifies the search, booking and payment of temporary resource usage, it profoundly alters our idea of owning and consuming. The basis of sharing economy is the idea of resource managing optimizing and expense reducing because of the shared access (together access) to them. Co-living, as one of the brightest forms of sharing economy, is oriented at the housing sector and offers an alternative to traditional models of rent and

* Corresponding author: rastislav.kotulic@unipo.sk

real estate purchase. It is focused on the housing community formation and provides tenants with an access to common space, services and infrastructure; it shapes the sense of community and reduces individual housing expenses.

Looking at constantly speeding up social and economic transformations, the concepts of sharing economy and co-living are acquiring a special meaning. The concepts reflect a new approach to resource management and influence the formation of up-to-date social models and lifestyle. The current article is aimed at the all-sided research of sharing economy and co-living evolution - via state-of-the-art context and considering them as crucial components of modern social and economic system. The analysis goal is a comprehension of present-day development trends, highlighting prospects and potential problems that may be connected with their integration, further evolution (including legal aspects, security issues and sustainable development). Aside from that, we are to analyze a co-living impact on the real estate market and its social role in the formation of city communities.

2. Literature and research survey

Co-living studying as a phenomenon of sharing economy has been attracting more and more attention in the recent years. It reflects wider urbanization trends, housing accessibility and community dynamics. The research has singled out several primary topics and directions in terms of co-living - especially via the context of its evolution and impact on urban life.

One of quite considerable fields of the research is people's motivation to participate in co-living projects. According to the research, motivation may vary from economic background - such as housing expenses decrease and resource co-usage - to social factors including inclination to communication and community formation (Vereshagina and Korshunova, 2021).

This motivation duality underlines a complex character of co-living in which economic and social aspects get intertwined and influence tenants' experience and contentment (Goryachkina, 2023).

Another important co-living research aspect is structural characteristics of successful projects. It has been proved that efficient management practices, tenants' involvement into decision-making and presence of supporting infrastructure are the key factors for creating positive co-living environment (Pupentsova, 2022).

On the contrary, the projects which lack the above mentioned elements frequently come across the problems as follows: shortage of financing and unclear operation frames - and it can become an obstacle to their stability and growth.

A comparative analysis of international co-living models has also become a significant part field of the research. While exploring global experience, the researchers have discovered the best practices and innovative approaches that can present information about the development of co-living in various cultural and economic contexts (Balakina and Pavlyuk, 2022).

This comparative prospect is especially relevant in terms of understanding how co-living may be adapted in order to meet the demands of local necessities and relying on successful strategies from other regions (Golovin and Korotkova, 2023).

Besides, the application of analytical frames - such as SWOT-analysis - has turned out to be useful for the estimation of strong and weak sides, possibilities and threats connected with co-living initiatives. This approach gives us an opportunity to make a complex estimation of co-living landscape - it highlights key factors that influence its survivability and growth potential within wider sharing economy (Voronkov and Elfimov, 2023).

The literature on co-living opens a multi-aspect phenomenon that intercrosses different social, economic and cultural measurements. As long as urban locations pursue developing, the role of co-living and community formation mechanism requires further study - especially in the context of changing economic reality and society necessities (Mirgorodskaya, 2018).

Co-living can be considered as a process that includes:

1) impact of social and economic factors on the community formation - it can be depicted on different levels of participants' involvement and their capability to adapt to new conditions (Oghienko, 2024);

2) application of innovative approaches towards space and interaction organization - it influences, in its turn, the mechanisms of formation and social-bond maintaining among tenants (Shlegel and Generation, 2022; Sonina, 2022);

3) adaptation of co-living management and interaction models - a special meaning here is given to the flexibility of organization system and character of changes which may be initiated by the participants themselves or external circumstances (Taranov and Basenko, 2023; Protasievich, 2023; Sapozhkova, 2022).

Therefore, co-living is a dynamic eco-system that provides interaction of various factors and participants for living and working together, and it requires further analysis and study (Dolinskaya and Yakovenko, 2021).

Future research should aim at deepening of understanding of co-living dynamics and exploring strategies of its enhancing impact on urban life.

3. Methods

A few methods envisaging an integrated approach to the topic have been applied in this article on the analysis of the Russian sharing economy development on the case of co-living as an example. When applying an integrated approach, technical, environmental, economic, organizational, and social aspects of activities and their interrelationships should be taken into account (Mustafin et al., 2019). A qualitative analysis is most notably used for bringing to light deep-laid social and cultural aspects of co-living. Speaking about the above mentioned method, semi-structured interviews with co-living tenants, real estate managers and experts are held - it all can present a picture of motivation, preferences and co-living tenants' experience, moreover, public opinion on co-living as an economic model in different regions. Aside from that, in order to estimate the popularity of co-living and its impact on economic indicators, a quantitative analysis, based on open-source statistic data and target public's questionnaire results, is applied. All this permits to hold a comparative analysis of various co-living models and their efficiency in different regions of Russia.

Moreover, certain examples of successful and unsuccessful co-living projects with the application of case-stage technique, are in the centre of study - it enables to bring key factors into sharp focus (the factors that trigger the model development) and analyze their impact on local communities. In addition, we apply SWOT-analysis for the estimation of co-living's strong and weak sides, possibilities and threats connected with its development in terms of Russian economy and social structure. Therefore, combining these methods brings the possibility of getting a full-scale picture about co-living development - as an element of sharing economy in Russia; it helps to work out recommendations for its further implementation and optimization.

4. Results

Monitoring the level of citizens' income, their structure, as well as the calculation of the degree of income differentiation of various population groups, allows the state to determine the direction of social and economic policy (Vasilova et al., 2018). The idea of resource co-usage is not new, its re-considering in the context of sharing economy and co-living is also an up-to-date phenomenon. Internet-technology and mobile application evolution has simplified the processes of resource exchange and co-usage that promoted the development of these practices at the beginning of the XXI century. The re-considering of traditional approaches to owning and renting, as well as enhancing an inclination for sustainable development and resource usage optimization, have become the priority factors - the ones that maintain the growth of sharing economy and co-living popularity.

The analysis of sharing and co-living requires the introduction of economic, social and urban aspects. The science of Economics studies resources allocation, the science of Sociology focuses on the alteration of social norms, Urban Studies - the impact on city environment. It is crucial for the understanding of modern social and economic alterations and their influence on society and city.

The research of sharing and co-living includes the analysis of their influence on society and economy. We are to consider positive and negative aspects of these concepts, their current trends and possible challenges. As a result, we are to make conclusions and offer a range of directions for further research.

Speaking about sharing economy, we can firmly claim that it has been developing strongly during the last decade. Since 2013 on, the market has increased 25-fold and reached the volume of 387,1 billion US-dollars (From Houses to Clothing, 2024). The future prospects of sharing economy can be seen as optimistic: according to the estimations of analysts, from 2023 to 2032 the resource co-usage consumption will have been demonstrating a 7,7% growth a year; up to the end of this period the

world market of sharing economy may have reached 827,1 billion US-dollars (Sharing Economy Market Size, accessed on 23 February 2024).

The sharing has many forms: even routine services have appeared as a consequence of sharing economy evolution. There is a multitude of sharing types - however, not all of them have received their further development. On the basis of the analysis of scientific literature, magazine articles and internet sources, we have singled out the most wide-spread forms (see Table 1). Each type of sharing has received our definition and a possible reason of popularity. The comparative analysis of these reasons can give us a possibility to highlight general development trends of the co-usage consumption models.

Table 1. Popular types of sharing

Type of sharing	Explanation (definition)	Possible popularity reasons
Car-sharing	Short-term vehicle (car) rental	High car and taxi pricing, parking difficulties
in large cities		
Co-living (flat-sharing)	Format of community living, when soulmates can live in one apartment or house	High property pricing in large agglomerations
Kick scooter sharing	Short-term scooter rental	Traffic jams in large cities, high client's mobility, expensive taxi
Bicycle-sharing	Short-term bicycle rental	Possibility to combine physical activity and road, traffic jams in large cities, expensive taxi
Equipment and tool sharing	Short-term construction tool and equipment rental	Tool expensiveness,
Outfit rental	Suit, costume rental	Outfit expensiveness, photography development
Libraries	Public book usage	Expensiveness of paper books, one-time usage, ECG lifestyle
Book-crossing	Paper books exchange	Expensiveness of paper books, one-time usage, ECG lifestyle, desire to share
Media-services	Using i-nets for scrolling content	Convenience of usage, digitalization, accessible price
Co-working	Co-usage of working space	Convenience of usage, cheaper than office rental, possibility of changing your work
Team shopping	Consumers' wholesale buying cooperation	Cheapening of shopping prime cost

Source: compiled by the authors based on sources: Plotnikov and Anisimova (2023); From Houses to Clothing (2024).

Referring to the table in general, we can note that digital technology development has become a chief growth driver of practically all types of sharing: 20 years ago it was almost impossible to imagine that a click of a few smartphone buttons would make transaction via electronic banking, call a taxi, choose a hotel, etc. And today there are a lot of digital services simplifying people's life and it has settled into a routine.

One more growth factor has been triggered by the expensiveness of things. The cars are high-priced - we can say the same about apartments, a purchase of which has got almost inaccessible for regular consumers, so many of them prefer renting apartments or co-living.

Sharing usage is about certain mutual profit for consumers: there is a possibility to stay in one place, make new bonds, exchange experience.

Technologically speaking, as we see it, a chief driver of growth is economy digitalization and development of new technologies that provides interaction between suppliers and consumers.

We have also paid attention to the fact that the widest institutional development goes to the types of sharing that are connected with the so-called "splittable" life-comforts of high price (apartments, vehicles, etc.).

The brightest example of this growth is “Delimobil” IPO companies that offer short-term car rental (News, 2024). The companies working in the sphere of sharing economy have been transforming from start-ups into strong businesses.

Still there are sharing forms that have not received any further popularity: personal outfit sharing, sharing of pets.

In our opinion, the above mentioned forms have received zero feedback for a number of reasons: a consumer cannot be fully sure that the outfit he/she rents is clean enough and there are no traces of overusing that may possibly be left from a former consumer. Many people feel unpleasant with the idea that your clothes may not be ideally clean and it touches your body. The clothes issue is about lots of individual traits: size, cut, colour, etc. It is quite difficult to meet everyone’s demands. Pets are living beings that evoke deep emotional feeling of bond with humans. Moreover, constantly changing owners are not a good thing for pet’s health - it is quite negative.

Therefore, having analyzed the most popular forms of sharing, we have arrived at the conclusion as follows: some types of sharing have started their active development thanks to the expensiveness of sharing objects and increasing economic efficiency of using the comforts via sharing. Meanwhile, the types of sharing that have not received their development were directly connected with a consumer (they have individual characteristics or evoke strong bonds).

5. Discussion

Legislative framework in force

Currently definite legislative norms regulating such form of community living as co-living are absent in Russia.

The absence of the legislative framework regulating co-living activity is connected with negative consequences. Firstly, the uncertainty of legal status of the housing sector segment, high business and consumer risks. Secondly, the absence of investment incentives and innovation approach development in the sphere of residential construction.

Practically, present-day Russian co-livings use the norms of hotel legislation. Hotel work in Russia is based on a number of regulatory legal acts - the Government Regulation of the Russian Federation N 1860 which defines a classification of inns (hotels), however, does not consider co-living as one of the categories (Government Resolution of the Russian Federation "On Approval of the Regulation on Hotel Classification", accessed on 19 February 2024). Due to the absence of clear legislative regulation, co-living does not have a certain status - it brings legal uncertainty and increases risks for economic players and tenants of the house where illegal co-livings may be located. And in accordance with Part 3 Section 17 of the Housing Code of the Russian Federation, the location of hostels is prohibited in block-of-flat type houses (1. "Housing Code of the Russian Federation", accessed on 26 February 2024).

The uncertainty of the legal status challenges the interaction between exchanging parties and it can restrain further development of this sector (The Communal Apartment Syndrome, accessed on 19 February 2024). The absence of legal regulation of co-living hinders effective housing resource usage and limits the access to alternative housing forms and innovative housing services. This, in its turn, hampers the growth of competitiveness of the housing branch and triggers negative tendencies for macro-economic development. In order to provide sustainable and efficient housing market functioning, special laws and regulations should be created for setting clear legal frames for co-living. Both entrepreneurs and service-consumers would have protection from the law. The sphere regulation could stimulate investment, increase the housing service quality and enhance macro-economic indicators of the housing market development in Russia (Rambler/Finance, 2021).

Co-living prospects

Co-living as a community living form attracts more and more attention, especially among young people, students and digital nomads. We have inquired 1135 co-livers of the Volga region federal area in order to highlight basic problems and advantages of co-living.

Possibilities of co-livings:

1. Social integration. And again it can be noted, that private life directly affects other aspect (Rudaleva and Mustafin, 2017). Co-living offers a unique possibility for social integration especially for people moving to a new city or country. 74,6% of respondents noted that co-living has assisted in

making new bonds, new friends; about 72,1% of respondents underlined communication with other people as a primary benefit of community living.

2. Economic accessibility. Co-living frequently turns out to be more economically profitable in comparison with apartment renting or property purchasing. Utility fees included into the rental value and a zero necessity to purchase furniture and appliances make co-living especially attractive, financially speaking. It has been confirmed by 68% of respondents who have underlined financial profit as a decisive factor to choose co-living. The topic is especially acute for the age-group of 21-25 years old - 88% of respondents have noted financial profit.

3. Flexibility. One of the key merits of co-living is renting conditions flexibility. A possibility of medium-term - and partly short-term - renting attracts temporary housing seekers and those whose life circumstances change quickly. Flexibility has been marked by 62% of respondents. According to these co-livers, a quick change of location is relevant (31,3% of respondents), going on a longer trip (45% of respondents), moving to a different city (21% of respondents), etc.

Risks:

1. Lack of personal space. Limited personal space may become the source of stress for some co-livers. A considerable part of respondents (86%) has pointed out this as a problem - it underlines the necessity of creating spaceous well-planned housing zones.

2. Problems with tidiness. Common areas require regular cleaning and order maintenance - especially in case of many co-livers. Many co-living tenants (51,8%) of economically lower price segment have complained about mess and dirt in bedrooms, and more than a half of respondents (57%) - about disorder in co-usage areas.

3. Confidentiality and safety. Confidentiality and safety of personal belongings may also cause worries with many co-living tenants. Almost half of respondents (47%) have expressed their feeling unsafe in terms of secrecy while telephoning and messaging.

4. Absence of clear legislation-confirmed community rules. 42% of respondents have noted that they are not aware of their housing rights in co-livings, 54% - that local rules set by co-living administration is insufficient as they do not cover relations between a tenant and a renter.

We have estimated a three-factor model that has been received by means of Excel package - it expresses dependence of a co-living number in a region (y) on a number of students in a region (x1), and a number of middle-aged people co-living in different regions (x2), and a number of people who believe that co-living expands horizons and welcomes new social bonds and acquaintances (x3):

$$y=44148{,}665+0{,}271*x1-2009{,}128*x2+0{,}819*x3 \quad (1)$$
$$(2{,}67)\quad (7{,}92)\quad (2{,}53)\quad (7{,}73)$$

Checking the practical meaningfulness of the coefficients, we may conclude that in all the cases we see Prob<0,05. Therefore, the coefficients are meaningful on the accepted reliability level, and the factors that we have singled out (x1, x2, x3) influence the number of co-living in a region. According to statistics, the Fisher coefficient illustrates the reliability of the model, Prob (F-statistics) shows the value of 0,000001. Aside from that, the analysis of correlation matrix of all factors proves the absence of multicollinearity.

Estimating the calculation data of the regression table, we can summarize that the coefficient of determination equals R=0,78. In other words, 78% of X-factor alteration cases lead to Y-alteration, as long as the segment of blind spots (non-marked factors) in the considered model equals 22%. Consequently, the interconnection among the factors is quite strong.

As the equation (1) shows, the larger the number of students in a region and believers in co-living as priority of social bonds is, the larger is the quantity of co-livers, who co-rent a flat or apartments, and v.v. However, the older they get, the fewer the number of co-livers becomes.

We can also claim that with a 1% student number increase in a region, the number of co-livers also demonstrates 0,54% growth OTE (other things equal). As the number of co-living-friendly people shows 1% growth, the co-living number is to show 0,46% increase in average OTE. Meanwhile, in case the average age of co-livers shows 1% increase, the number of people renting a flat together may show 0,37% decrease OTE.

Co-living offers a lot of possibilities for consumers including social intergration, economic profit and housing conditions flexibility. However there are certain risks such as limited personal space,

problems with cleanness and anxiety about safety. To minimize the risks, co-living operators have to carefully plan the space, provide regular cleaning and implement effective safety measures.

Development prospects

The Russian Federation does not have the legal framing on regulating co-living objects. However we can offer a range of recommendations and standards that may simplify the life of our consumers and bring them comfortable living:

1. Introduction of measures regulating quality and safety standards while co-living renting (Standard Agreement of LLC "COLIVING", accessed on 16 February 2024):

1.1 co-living companies have to provide all essential information on the quality and safety standards - the standards residential premises should meet. Minimal requirements on the condition of co-living residential premises equipment should be set, as well as sanitary-and-hygienic and communal conditions should be observed;

1.2 regulation setting on following “silence hours” at certain time should be observed - in order to provide rest period for all participants;

1.3 determining the minimal floorspace of residential premises, an obligatory presence of own rooms for each consumer;

1.4 guaranteed by the agreement access granting to appliances, furniture, internet and television, and common areas: kitchen, living room, gym hall and swimming pool (the list of offered services may vary - it depends on co-living company conditions);

1.5 presence of FSS (fire safety system) and emergency warning in common areas. Regular check-up of electronic equipment to prevent electric out-of-balance load;

2. Obligatory licensing for co-living residential property. The measure is to protect consumer rights in case a consumer faces problems with a co-living operator. Licensing also guarantees the quality of housing and proper living conditions.

3. Setting rules on rental and life in co-living housing

3.1 determining a clear and transparent rental contract, procedure for the conclusion of a rental contract, period of residence and possibility of contract dissolution (Standard Agreement of LLC "COLIVING", accessed on 16 February 2024).

4. Implementation of efficient monitoring mechanism of the choice of co-living neighbours:

4.1 Recommended for implementation: effective neighbour-choosing process for the rental procedure, an algorithm of partner selection on the basis of potential co-livers’ character features and preferences analysis. The algorithm based on individual preferences can optimize the neighbour-choosing process for ideal matching in terms of lifestyle and interests. This approach is good for enhancing the quality of interaction and comfort of co-living, which is an extremely crucial aspect for harmonized neighbouring environment in rented residential premises.

Potential consumers of co-living have been surveyed - the survey was based on our recommendations on applying standards and requirements for better co-living.

The survey says 78% of potential tenants of property agreed on the first point: “Introduction of measures on regulating quality and safety standards for co-living rental”. They marked the importance of sub-points 1.1, 1.2, 1.3 which says about the necessity to provide comfort for clients.

As for the second point, 60% of the surveyed agree with it: all requirements offered by co-living operators are to be satisfied in the case. However 35% of respondents disagree with this measure: licensing may influence rental of premises increase and bring their financial status to the negative mode.

Speaking about the third point “Setting rules on rental and life in co-living housing”, 80% of respondents agree with it. Many of them underlined the necessity of making a clear and transparent rental contract.

85% of respondents agree with the last point of the survey. The chief argument is as follows: good neighbouring is a basis of calm and friendly co-living. Moreover, a possibility to live with people who have common interests is one of the priority aims of tenants of property.

To summarize, the results of the survey and our monitoring have enabled to conclude that consumers are interested in co-living housing regulation. Firstly, a clear and transparent rental contract is definitely conducive to the trust from potential consumers. This is a key factor for this direction development in Russia. Secondly, the implementation of efficient monitoring mechanism of choosing

neighbours may increase co-living ratings, its popularity among young people. More consumers would like to have a try co-living with people who their views and values coincide with. Thirdly, the implementation of measures on regulating quality and safety standards is to become one of the decisive factors in terms of choosing co-living as a place of permanent residence.

Conclusion

In the course of the survey the key aspects of sharing and co-living as crucial elements of modern social and economic paradigm have been considered. The analysis of literature and current practices has shown that these phenomena do not only reflect the alterations in consumer preferences and technological development, but may become a powerful trigger of creating more sustainable and inclusive communities. Sharing economy and co-living demonstrate a considerable potential for optimizing resource usage, decreasing eco-unfriendly impact and consolidating public bonds. However, despite numerous advantages, these practices may meet certain challenges including regulation issues, keeping privacy and safety, and the risks of enhancing social inequality.

Further research in the field should concentrate on working out efficient mechanisms of regulation in order to keep the balance between innovation stimulation and the protection of rights of all the participants. Besides, an important direction for would-be research is studying long-term social and ecological consequences of sharing and co-living. Finally, we can claim that sharing and co-living make a considerable contribution into the formation of a more sustainable and flexible society. However, for a better potential opening, active participation of all interested sides is needed: the state, business and society. Only united work and efforts can provide the development of these practices in the direction of a more just, eco-friendly and inclusive world.

Abstract

Research background: Moldova is in the news more and more. It is a country that is still rather unknown to Europeans, with headlines varying from 'Europe's poorhouse' to 'Europe's next powder. In May, the status of Moldova was also raised in the context of the Romanian presidential elections, when one of the candidates campaigned again for the creation of a Greater Romania.
Purpose of the article: Recognition of autonomy gives national minorities certain rights, while it guarantees the state that these minorities recognise the political, territorial unity and sovereignty of the state. In Moldova, an interesting situation arose, where we can find both positive and negative examples to prove the above statement.
Methods: Seconder research was conducted by analysing the historical and theoretical background of autonomy. The choice of literature used in the analysis was motivated primarily by content and conceptual soundness rather than topicality. Economic performance was examined by using international institutes datasets such as the Word Bank, the IMF and the WIPO.
Findings & Value added: Tthe situation of the territory is very precarious from an autonomy perspective. We can even say that the borders of the country may change in the near future. History of Moldova is very closely linked to the concept of autonomy. The current conflicts could have an impact on foreign policy, stem from the desire for autonomy of each of the territories.

Keywords: Moldova, Concept of autonomy, Gagauz, Transnistria, the European Union

1. Introduction

Moldova's historical background

Between the 5th and 13th centuries, present-day Moldova served as a marching area for horse-riding nomadic tribes. Scythians, Thracians, Pechenegs, Cumans, and Huns also roamed here. Later, Kievan Rus, Poland, and Hungary wanted to integrate this area into their own borders.
During the reign of Louis, the Great, the Hungarians drove the Tatars beyond the Dniester, and thus, with the permission of the Hungarian king, the Principality of Moldavia was established (1359). The Principality was bordered by the Dniester to the east, the Carpathians to the west, and the Black Sea and the Lower Danube to the south.

Although they seceded from the Kingdom of Hungary in the following century, they remained in contact as allies, but in the mid-16th century they lost their independence to the Ottoman Empire.
Although a vassal relationship was established with the Ottoman Empire, the fate of the territory differed from the situation in the Balkans. They left behind the roots of cultural independence, which still affects the lives of the ethnic groups there today.

At the end of the 18th century, national demands also appeared in this area, and from 1812 the history of the former Principality continued in two threads.
Bessarabia, located between the Prut and the Dniester, became part of the Russian Empire, the area initially received a certain autonomy, but then lost it after the Russo-Turkish War of 1828-29. Culturally, its identity was increasingly determined by the Russian language and culture,

* Corresponding author: nagy.zsuzsanna@nye.hu

From 1834, the use of the Romanian language in education and church liturgy was gradually suppressed, and after 1850, the import of books in Romanian was banned.

In contrast, the area between the Carpathians and the Prut is dominated by the linguistic and cultural challenges of the Principality of Havasalföld, which considered the awakening of Romanian national consciousness as an important task.

In 1918, this territory was annexed to Romania, but the Soviet Union did not recognise the annexation. In response, the Moldavian Autonomous Socialist Republic was created in 1924 within the Ukrainian Socialist Federal Republic. The undisclosed aim was to weaken the creation of Greater Romania. The relatively small area of Moldovan autonomy could only be retained within the Ukrainian Socialist Federal Republic for Soviet interests.

In 1940, the territory was annexed to the Soviet Union under the Molotov-Ribbentrop Pact, and the Moldavian Soviet Socialist Republic was created.

World War II did not change the situation, and the inhabitants of Romania and the Moldavian SSR became increasingly distant from each other. In terms of identity, they became more and more detached from the Romanian identity, although they used Romanian language but wrote in Cyrillic letters, and the Soviet way of life and culture became dominant.

In 1991, after the break-up of the Soviet Union, these areas also underwent major changes: in May, the Republic of Moldova was incorporated. At the end of August, the Republic declared independence, but with Soviet help a thin strip was torn off and a new one was established east of the Dniester. Thus, the Transnistrian Republic (Transnistria) was created, with Tiraspol as its capital. Moldova rejected this, and the breakaway territory fought a short war with the central power.

The parties concluded a peace agreement on 21 July 1992, the essence of which was that the Moldovan authorities would have no say in the politics of the territory but would not recognise its independence and would continue to consider it part of Moldova.

To date, the Transnistrian Republic of Moldova has not been recognised by any state, despite repeated requests for its admission to the UN as an independent state after Kosovo's recognition.

There are currently 2,600 Russian “peacekeeping” troops stationed there and the Transnistrian “army” still holds the Soviet army's abandoned weapons stockpile to ensure the territory's survival as a country. The war in Ukraine has put further strain on the situation, but the “autonomy” of the area remains in place.

It can be seen that the creation and history of Moldova is very closely linked to the concept of autonomy. The current conflicts, which could have an impact on foreign policy, stem from the desire for autonomy of each of the territories (Cretu, 2025; Osipov, 2019; Ratzmann, 2014).

2. Methods

2.1 Introduction to the concept of autonomy

The aim of this section is to clarify and introduce the concept of autonomy. Autonomy springs from man's desire for freedom, insofar as the majority of people wish to minimize outside influence in shaping their lives for their own happiness and well-being, because ultimately a free man can decide for himself what is good for him (Tóth, 2014).

In order to understand the conceptual and substantive elements of autonomy, minority rights must first be introduced.

In state theory, autonomy always expresses a group's desire for freedom of choice. The desire for freedom to decide one's own affairs may arise within a state when that state does not allow someone to decide their own affairs. This need is most likely to arise in the case of a group that is in a minority position in relation to the majority within the state because of some characteristic/property. These minority groups may formulate minority claims.

The use of the term “minority” may arouse resentment in many people, because members of a group may demand that the state take account of their specific characteristics and, if necessary, treat them differently on the basis of these characteristics.

The creation of a state is always the result of an artificial process, whereby a sovereign power is organised that can and will regulate the lives of a population living in a defined area. A problem can arise when the people living in a given territory do not belong to the same ethnic group/ethnicity. If only groups of people with the same language, the same roots and the same culture live in the territory of the state, conflicts between different ethnic groups will not arise.

However, in a given territory, different groups may exist on the basis of different languages, cultures, religions or traditions, common memories or values. These groups can only live side by side if they are able to accept their differences as a criterion for the recognition of a different group in the community.

If a group with different attributes is growing in number relative to the majority, their acceptance becomes more problematic, as those in political power may fear them. The fear may be triggered by the assumption that this minority group also wishes to gain political power or at least wants a share of it. In many cases, this fear is not only expressed by denying these groups the right to recognise otherness different from that of the majority, but the majority may even seek to "eliminate" the group through forced assimilation. An example of this can be seen in the history of Moldova, when the Bessarabia region was annexed to the Russian Empire and from the 1860s onwards the use of Romanian was gradually replaced by Russian, with the result that the population was also replaced, as the Romanian-speakers who had left the country were replaced by Russian-speakers from the interior of the empire.

The strongest, but also the most controversial, minority rights are autonomy, and the rights associated with claims. The problem may be generated by the conceptual tensions between the sovereignty of the inhabited territory, the homeland, the nation-state. The right to autonomy can be claimed on the basis of a territorial or personal principle.

According to (Vizi, 2006), there are two types of autonomy: "Territorial autonomy is when a given nationality is in a majority in a specific territory or region of a country, so that it can benefit from public authority in its own right. In this territory, this minority, i.e. the local majority, has its own decision-making and executive institutions in accordance with the laws and constitutional arrangements of the state."

In addition to territorial autonomy, we can also speak of cultural autonomy (or non-territorial autonomy), which operates on the principle of personal autonomy. In this sense, it is not linked to a specific territory, but always to a national minority in the country, which is the main facilitator of the exercise of cultural rights by this minority, especially through rights related to language and education.

Even if the right to autonomy is guaranteed, states always specify its content: usually only the right to cultural autonomy is understood, while the right to territorial autonomy is usually excluded.

The right to autonomy is primarily linked to the concept of self-government and does not always have to be accompanied by the idea of separation from the state. The same problems of understanding can be observed with the concept of autonomy as with the rights of national minorities. Even here, the individual states have not been able to agree on a common concept. There are states that accept it, and others that deny it completely. It is also important to note that minority rights, including the right to autonomy, can only be imagined in a democratic state.

According to Swiss political scientist Andreas Gross, autonomy as a concept should be an inherent part of strong democracies. The recognition of the right to autonomy is always part of the democratisation process. Autonomy does not eliminate conflicts, which are a natural part of democracy, but it does reduce violent conflicts; autonomy avoids conflicts escalating into violence. Autonomy is part of strong democracies, and the concepts of democracy and autonomy are thus inseparable." (Kántor, (ed.) 2013:3)Recognition of autonomy gives national minorities certain rights, while it guarantees the state that these minorities recognise the political, territorial unity and sovereignty of the state. Based on his book regarding ethnocultural rights, Pentassuglia does not see territorial autonomy as the highest goal to be achieved but also mentions other possibilities in this regard. "Territorial autonomy in the sense of a grant of decision-making authority in a number of areas intended to benefit a sector of the population, which is located within a geographically defined unit, may not be the only – or even the most desirable – solution in all circumstances requiring group accommodation. Territorial autonomy, just as non-territorial one (or a combination of both), is a means to an end, not an end in itself." (Pentassuglia, 2018).

3. Results

3.1 Status of autonomy in Gagauz

In Moldova, an interesting situation arose, where we can find both positive and negative examples to prove the above statement.

After 1991, in the processes of independence, the demand for the right to self-determination arose in two different areas of the country. In one place, the issue was resolved by maintaining the status of autonomy, as we can see in the case of the territorial autonomy of Gagauzia. In the case of Transnistria, this was not enough for the residents there, and they chose to secede from the Moldovan state. (Although it can be argued here that the will of the local residents was not the primary one, but rather dictated by Russian political interests)

The Gagauzian autonomy illustrates some of the key challenges of elaborating and implementing autonomy provisions in the context of fledging democratic institutions and a weak system of rule of law. Although the Gagauz autonomy is often considered as a rare case of successful conflict transformation in post-Soviet space, the actual implementation of autonomy provisions has been a highly contested issue (Protsyk, 2009).

Gagauzia is a very small area, not large on the map of Moldova anyway. Its population does not exceed 170.000 inhabitants. In fact, many people emigrate in search of a better life. The inhabitants have a very modest economic position, living mainly from agriculture and selling their products in the nearby areas.

However, two factors have helped to give this relatively insignificant area territorial autonomy. One factor was Russia's foreign policy interests. After 1991, there was a growing desire for relations, even union, between Moldova and Romania. Russian policy wanted to prevent this. The beginning of the EU accession process further strengthened the Russian desire to somehow block Moldova's relations with Europe/Romania.

The other state is Turkey, which supports Gagauz autonomy from the outside. The Gagauz are the only ethnic group of Turkish origin that is not Muslim but Orthodox. Their Turkish national consciousness is strong, but there are already uncertainties about the use of their language. The Turkish language is mostly used only at home, while Russian is more common in official places. They are most afraid of their identity being dominated by Moldavian (Romanians), which is perhaps why they are turning to Russian language and culture. But they receive a lot of help from the Turkish state in maintaining their identity.

The 1994 autonomy agreement, which established the self-government of Gagauzia within Moldova, is also credited to Turkey's President Suleyman Demirel. Süleyman Demirel was able to play a role in the Gagauz's interest because Moldova was facing significant ethnic tensions after the collapse of the Soviet Union and was unwilling to risk a fragile peace.

The Autonomy Agreement established Gagauzia as the Autonomous Territorial Unit of Gagauzia (ATUG) and gave it the right to manage internal affairs in areas such as education, culture and local governance. Crucially, the agreement also recognised the right of the Gagauz to secede if Moldova lost its independence - a clause designed to address fears of possible unification with Romania. (Karahindiba, 2024).

Although in 1994 it was probably only the image of Romanisation that was frightening, since then it is possible that the globalisation effects of the EU could set in motion processes that the Gagauz believe could lead to the loss of Moldova's independence. These perceptions have been reinforced by the political situation since then.

On 15 October 2024, the EU added Evghenia Guţul, Governor of the Autonomous Territorial Unit of Gagauzia (Başkanja), to the sanctions list for promoting separatist aspirations in the region and thus attempting to overthrow the constitutional order and threatening Moldova's sovereignty and independence (EU Council, 2024).

The President was joined on the sanctions list by Mihail Vlah, Vice Governor of Gagauzia (Başkan) and Media Relations Advisor, Iurii Cuzneţov, Vice Head of the Foreign Affairs Department of the region, and Illia Uzun, Vice Chairman of the Executive Committee and member of the Gagauz National Assembly. The assets of listed persons shall be frozen, and it shall be prohibited to make funds or economic resources available to them, whether directly or indirectly. In addition, sanctioned persons will not be allowed to enter the territory of the EU. This can be a problem because the Gagauz leaders are not able to attend the EU bodies' meetings, to negotiate and to participate in the Gagauz interest group in the field. The EU has no regulations on ethnic minorities. It expects the candidate countries to settle such issues before accession, as it does not want to complicate relations between member states with this type of debate.

3.2 Transnistria as a state

On the map of Eastern Europe, there is a strange, almost timeless world - a breakaway territory that we barely know, yet has its own government, flag, army and even its own money. This is Transnistria, or officially the Transnistrian Republic - a state that virtually no one in the world believes exists yet is very real. Its capital, Tiraspol, looks as if it was left over from the Soviet Union: Among Lenin statues, red stars and Russian soldiers, another world exists in the middle of Europe (Morvai, 2025).

After the collapse of the Soviet Union, the mainly Russian and Ukrainian minorities living east of the Dniester River feared for their identity. On 2 September 1990, the region declared independence as the Transnistrian Moldavian Socialist Republic, with Tiraspol as its capital. Moldova rejected this, and the breakaway region even fought a short war with the central authorities (the separatists were helped by troops of the 14th Russian Army in the area).

The parties concluded a peace agreement on 21 July 1992, the essence of which was that the Moldovan authorities would have no say in the politics of the territory, i.e. it was an unspoken guarantee of territorial autonomy. But Moldova does not recognise the independence of the territory and continues to consider it part of the country.

The "non-existent" state has repeatedly applied to join the UN, citing Kosovo as an example, but has never succeeded. In the winter of 2025, hundreds of thousands of people were left without gas, for which Western aid was offered, subject to certain conditions being met. The Transnistrian leaders have accepted this offer, giving the Moldovan government greater influence in the breakaway region. Although Russian influence is still very strong in the area, this can only be changed by the removal of the 14th Division.

We can certainly say that the situation of the territory is very precarious from an autonomy perspective. We can even say that the borders of the country may change in the near future. In the case of the European Union, this is a very sensitive issue, since the existence of the common market requires the precise delimitation of external and internal borders. The European Union must certainly be forward-looking in its preparations for the entry of Moldova.

3.3 Moldova as a possible part of Greater Romania (Romania Mare)

In this chapter, it is also worth examining a possible scenario: the historical background shows that Moldova's independent status depended only on external forces, the will of the Western powers and Russia. The idea of a Greater Romania, with the rise of Romanian nationalism, had an impact on the Romanian-speaking inhabitants of Moldova.

In 1920, after the First World War, Transylvania, Bukovina, Bessarabia and parts of Banat, Gyria and Maramures were united, giving the Romanian state its largest geographical area (295 049 km^2) to date.

The idea of uniting Moldova with Romania is currently being repeatedly voiced by nationalist political forces. Nationalism is a site of struggle over the particular set of ideas describing the nation. In this process, the latter is instituted as a taken-for-granted re-presentation (Hall, 1997) of the social. This is achieved with the help of several key tenets that are generally stable: nations are said to have clear boundaries (both in terms of people and territory) and to be characterised by a culture (portrayed as shared systems of signification, belief, customs, etc.), temporal depth (historical presence) and common descent. Furthermore, nations are instituted as sovereign and intimately linked to a particular territory (Calhoun, 1997). These tenets are rooted in an ‘us’ vs. ‘them’ logic, where the drawing of boundaries around the nation heightens and, on occasions, creates differences (ethnic, linguistic, religious, etc.). The latter, in particular, are positioned as a threat to the very existence of the nation. (Dumitrica, 2019).

The Alliance for the Union of Romanians (AUR) keeps the idea of a Greater Romania on the agenda, promoting the integration of Moldova.

In the context of the war in Russia-Ukraine, European parliamentarian Sosoaca (the representative of AUR) proposed a bill to terminate the Romanian Ukrainian treaty of good friendship. She then wanted to annex territory from Ukraine for the benefit of Greater Romania (Rotaru, 2023). The AUR presidential candidate George Simion wins the first round of the re-run Romanian presidential election. However, he lost the second round by a small difference on 16 May 2025. Simion had accused Moldova of voter fraud, which allowed him to lose. There was no proof of fraud,

but it is more likely that the Moldovans wanted to keep their Romanian roots alive in an independent Moldova. By electing Simion, they did not want to help to power a politician whose dream was to create a Greater Romania in which Moldova would lose its independence and thus its autonomy of decision. (Bakk & Szász Alpár, 2010; Paun, 2025)

3.4 Moldova and the EU

The European Commission (EC) and Moldova signed the Association Agreement and Deep and Free Trade Areas (DCFTA) in 2014 and entered into force in 2016 July. It allows to assess to the European Single Market in selected sectors and to grant EU investors in those sectors the same regulatory environment in the associated country as in the EU. The DCFTA helps Moldova enhance its economic and trade integration with the EU in advance of accession. The EU has fully liberalised all imports from Moldova, except seven agricultural products. (European Commission, 2024c; Official Journal of the EU, 2014)

In 2022 Moldova applied for the EU membership and the Commission recommended candidate status and finally the European Council granted candidate status in June in the same year. In 2023 November the Commission recommended opening accession negotiations.

Accession negotiations were opened with Moldova at the first intergovernmental conferences in June 2024 and it has been an important recognition of Moldova's determination to pursue reforms on the path of EU accession despite facing continuous Russian interference and the impact of Russia's war of aggression against Ukraine.

Following the first intergovernmental conference the Commission started the bilateral phase of the screening process immediately. The Commission is looking forward to the opening of negotiations on clusters, starting with the fundamentals, as soon as possible in 2025. (European Commission, 2024a, 2025) A national referendum to anchor EU integration in the Moldovan Constitution took place together with the presidential election on 20 October 2024. The proposal to enshrine EU accession in the Constitution was supported by 50,38% of voters (European Commission, 2024b)

Between 2021-2024 the EU has allocated over €430 million in non-repayable grants to Moldova. These funds provide financial and technical assistance for social and economic development (European Union, 2024). In October 2024 European Commission adopted its annual Enlargement Package, providing a detailed assessment of the progress made by the Republic of Moldova. The assessments are accompanied by recommendations and guidance on the reform priorities. (European Commission, 2024a, 2025)New tools and instruments are boosting the socio-economic growth in this country. In addition to the successful Economic and Investment Plans, the Growth Plan for the Western Balkans with its €6 billion Reform & Growth Facility and the €50 billion Ukraine Facility are incentivising reforms, with justice and the rule of law at the core. Since 2021, the EU has mobilised €1.6 billion in Moldova. Funds are raised through tools such as the Neighbourhood Investment Platform. (European Union, 2024)

Last year in October the EU adopted a Growth Plan for the Republic of Moldova (1.8 billion euro) to support investments and alignment with the Union acquis and values and underpinned by a Reform and Growth Facility for the period 2025-2027. €400 million are expected to be grants and the rest concessional loans with long maturities. Reform areas include: competitiveness, economic resilience, economic governance, social capital, green transition, and public administration and rule of law. (European Union, 2024; IMF, 2024; World Bank Group, 2024).

The EU Economic and Investment (EIP) for the Eastern Partnership supports the investments needed to make the economies of the region more resilient and able to generate concrete benefits in areas such as transport, private sector, energy, environment and climate, water and sanitation, digital and human capital.

The EU remains deeply committed under the Common Foreign and Security Policy to deepen cooperation with Moldova. In 2024, Moldova became the first country to sign a Security and Defence Partnership with the EU. The EU has provided €137 million support to the Moldovan Armed Forces through the European Peace Facility (EPF) since 2021.

In light of the impact on Moldova of Russia’s war of aggression against Ukraine, the EU has mobilised special support measures, which include direct budget support, humanitarian assistance to support vulnerable Ukrainian refugees and families hosting them in Moldova, investments to support the Solidarity Lanes initiative that helps ensure secure supply chains and food security.

Since 2014, Moldovans benefit from visa-free travel to the EU. The EU has funded over 1 300 exchanges between EU and Moldovan citizens in the areas of education, training, youth, and sport under ERASMUS+ since 2021. (European Commission, 2024b, 2024c)

3.5 Economic performance

According to the (World Bank Group, 2024) and (BTI, 2024)country reports revealed that the Moldovan economy managed to rebound significantly in 2021 after the recession caused by the COVID-19 pandemic and related restrictions on economic activity, increasing more than 10 % compared to 2020, however GDP growth was halted in 2022. The Moldovan economy started to turn the corner in 2023; real GDP grew by a modest 0.7% compared to the sharp decline of 4.6% in 2022. This decline was the result of Russia's war of aggression against neighbouring Ukraine, a severe drought and energy supply disruptions. In 2023 the household spending was stagnated, and investment was balanced by strong net exports. Moldova's income per capita is just under a third of the EU-average. The National Strategy for Economic Development was adopted in June 2024 and its aims to kickstart economic growth and faster convergence.

Inflation has fallen steeply, from a high of 34.6% in October 2022 to 3.5% in April 2024. This disinflation was driven in large part by global food and energy and fuel prices falling. Additionally, Moldova experienced an inflation increase not seen in over 20 years. The inflation rate began to rise sharply in late 2021 and reached 34.62% in September 2022. (BTI, 2024)

While Moldova's public debt ratio remains relatively low, 37.2% of GDP in 2023, driven by the large primary deficit and higher interest payments on short-term domestic debt. The country has run large deficits in recent years, and liquidity management remains challenging.

The large account deficit was financed by net capital inflows in the form of currency, deposits and loans, while net foreign direct investment fell in 2023, to 2.5% of GDP from 3.7% compared to 2022. A new foreign direct investment and export promotion programme was prepared to counterbalance those trends. Moldova's external debt decreased as a share of GDP from 65.4%.

The general government deficit widened to 5.2% of GDP in 2023 compared with 3.2% in 2022 reflecting weak growth and the high cost of measures to support households and firms as well as higher interest payments. The government debt in the period from 2000 to 2022 was between 1.1 billion and 4.9 billion USD. The highest level of the last years at five billion US Dollar was reached in 2022.

Looking ahead, fiscal policy will need to increase much-needed public investment to support the recovery while ensuring sustainability via consolidation that protects growth-enhancing spending.

Nevertheless, while ensuring fiscal sustainability, Moldova will need to increase public investment to begin converging to EU income levels. Major risks are related to the possible interruption of the current arrangement for natural gas supply from Russia to the Transnistrian region. (European Commission, 2024b)

However, Moldova has continued to steadily progress on its EU accession path (European Commission, 2024c)The Moldovan people voted on 20 October 2024 in a referendum on EU accession and in the presidential election. The proposal to enshrine EU accession was supported by 50,38% of voters.

According to the (IMF, 2024) report the economic activity shows a pick-up in 2024 with stronger private consumption and investment.

Moldova further improved its alignment with the EU common foreign and security policy by continues implementing a comprehensive justice reform. Further consolidating anti-corruption institutions, proactive and efficient anti-corruption investigations and convictions at all levels will underpin the building of a solid track record.

The country continued deoligarchisation efforts and launched investigations and prosecution of illegal financial flows and voter bribery. Collaboration with European and international agencies to fight international criminal networks should continue and be further reinforced. Additional efforts are necessary to reinforce the independence of public media and increasing media ownership transparency.

Despite all, the Corruption Perceptions Index (CPI) for the public sector showed 42 out of 100 points for 2023. With this result Moldova ranks 76th. So, compared to other countries, it is slightly below average. Compared to the previous year, the level of corruption decreased a bit. In the long

term, it has also declined moderately in recent years. (Valérian, 2024). The CPI ranks a country by its perceived levels of public sector corruption, scoring on a scale of 0 (highly corrupt) to 100 (very clean). Over two-thirds of countries score below 50 out of 100, which strongly indicates that they have serious corruption problems. The global average is stuck at only 43, while the vast majority of countries have made no progress or declined in the last decade.

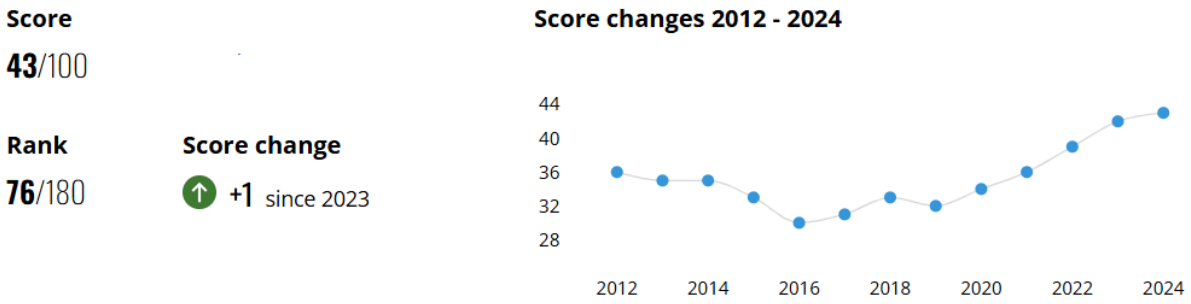

Figure 1. Moldova CPI ranking
Scource: Valérian (2024)

4. Discussion

Moldova is facing a critical moment as it seeks closer ties with the European Union while managing internal challenges and external threats. The country has EU candidate status and is pushing forward with reforms. However, Moldova still struggles with poverty, corruption, and regional divisions, particularly in the breakaway region of Transnistria and the autonomous, pro-Russian Gagauzia.

The war in neighbouring Ukraine has increased Moldova's vulnerability, especially with Russian troops still present in Transnistria. Moldova is working to reduce its reliance on Russian energy and improve ties with the West, but the path ahead remains uncertain due to economic instability and political opposition at home.

Conclusion

To navigate these challenges effectively, Moldova will need to foster collaboration with international partners, implement comprehensive economic strategies, and engage citizens in dialogue about the necessary reforms. However, the country requires comprehensive economy-wide reforms, build a more resilient and sustainable economy capable of withstanding external shocks and improving the quality of life for its citizens. Despite sustained economic growth over two decades, poverty remains penetrating, particularly in rural regions where access to services and viable economic opportunities is limited. The country remains vulnerable to converse weather events and energy shocks due to its heavy dependence on energy imports and limited diversification in energy sources.

With EU candidate status, strong reform momentum and growth-enhancing, climate-resilient investments are needed to foster long-term, sustainable development and convergence toward EU income levels (World Bank Group, 2024)

The Influence of Geopolitical Situations in the Middle East and Iran on the European Construction Sector in Cement and Concrete Production and Imports

Florian **Struck**[1,*] **and** ***Mária*** **Bohdalová**[1]

[1] Comenius University Bratislava, Department of Economics and Finance, Faculty of Management, Odbojarov 10, 820 05 Bratislava, Slovakia

Abstract

Research background: The paper examines the impact of geopolitical developments in the Middle East and Iran on the European construction industry, with a focus on the configuration of cement and concrete production and imports. It examines how regional conflicts, trade policies, and economic sanctions affect supply chains, production costs, and market stability in Europe. The study also examines the impact of foreign contracts and the strategic responses of European construction companies to these geopolitical challenges.
Purpose of the article: This paper aims to identify the impact of conflict, trade sanctions, and regional instability on the European supply chain and pricing and project delivery in the construction supply chain.
Methods: We employed thematic analysis, which enables us to identify, analyse, and interpret various sources, including scientific journals and political information.
Findings & Value added: The European construction sector, a key driver of economic activity, is highly vulnerable to external disruptions in the supply and prices of its primary materials – notably cement and concrete. Rising geopolitical tensions between the Middle East and Iran have led to significant fluctuations in material prices, logistical uncertainties, and project delays across the continent in recent years. These trends have increased the level of economic risk for construction companies, exposing them to global risk factors that necessitate adjustments in procurement strategies, project planning, contract structures, and pricing mechanisms.

Keywords: Cement manufacture, Concrete deliveries, Iran, European building activities, Supply chain interruption

JEL classification: E00, F14

1. Introduction

The materials to bind them together (Sverdrup and Olafsdottir, 2023). Cement production accounts for a sizeable European construction sector, the backbone of euro area economic activity, is dependent almost entirely on raw materials, among which are cement and concrete, as noted by Crawford (2022). They are more than just building materials; they are the basic building blocks of infrastructure projects, urban development, and industrial construction. Cement and concrete are strategic commodities that support housing policies, transport networks, and renewable energy infrastructure. In 2022, the EU construction sector accounted for approximately 9% of the EU's GDP, with around 18 million people employed in its value chain (Hafez et al., 2020). As such, this sector's performance is closely tied to the availability and cost of a few essential materials, with cement and concrete being the primary drivers in both building structures and overall development goals.

Cement, in its basic definition, is a binding substance used in construction that sets, hardens, and sticks to other amount of greenhouse gas, which can be attributed to the complete excavation of limestone and the sealing emissions that occur during cement manufacturing. When combined with

* Corresponding author: struck2@uniba.sk

aggregates and water, it becomes concrete, the second most widely used commodity in the world after water. The EU has consistently required cement and concrete supplies, amounting to more than 250 million tons per annum (Karlsson et al., 2020). Although Europe features a mature and technologically sophisticated cement production centre, with significant producers in Germany, France, Italy, and Spain, home production has increasingly been supplemented through imports due to the convergence of environmental regulations, energy costs, capacity constraints, and geostrategic diversification of resources.

The movement by Green and the European Green Deal has imposed new constraints on energy-intensive industries, such as cement production (Lim et al., 2020). Tighter carbon tax measures under the EU Emissions Trading System (ETS) have increased costs, and some companies have reduced their home production or looked beyond bolstering imports. In addition, the drive for economic growth in Eastern Europe and post-COVID economic recovery programs have substantially increased demand—in some regions, faster than the local availability of building materials.

This article aims to provide a critical, systematic, and integrative analysis of the impact of geopolitical dynamics in the Middle East and Iran on the European construction industry, particularly in the areas of cement and concrete manufacturing and imports. It aims to identify the impact of conflict, trade sanctions, and regional instability on the European supply chain, pricing, and project delivery within the construction sector.

The following section gives a literature review. It determines the significance of economics and, in Europe, the dysfunctions of the construction sector due to the use of materials and unhealthy substances imported from geopolitically unreliable regions. Likewise, it explains the objectives and goals of the study.

The section 'Methodology' presents our methodological approach. The section includes the choice of peer-reviewed sources from Scopus and Web of Science, the criteria used to include papers in the analysis, and the approach used for examining geopolitical events and their consequences for commercial flow. A qualitative content analysis, along with a thematic analysis, provides both depth and scope of insight. The section 'Discussion' places the findings within a broader strategic and policy context. It analyses the weaknesses revealed by geopolitical dependencies and looks at how to enable European industries and governments to adapt. This section concludes with practical suggestions and opportunities for further research.

2. Literature review

We decided to critically examine the regional impact and influence of geopolitical events in the Middle East and Iran on the construction sector of the Middle East and the European Union, particularly concerning cement and concrete imports. Sergent and Smith (2024) and Tkachenko et al. (2023) conducted a systematic and methodical literature review. The objective of these reviews was to identify, summarise, and draw insights from research and professional opinion concerning the high-level connection between geopolitics, the global construction supply chain, and the cement and concrete industries.

Charles (2023) introduced "The Effect of Current Geopolitical Shift on MEA's Construction Industry," where he examined how shifts in diplomatic partnerships, regional rivalries, and economic sanctions have shattered supply chains, labour movements, and investment flows in the Middle East and Africa. Although the paper takes the broadest view of the MEA region, the article provides interesting analogies for the European context, particularly in terms of the spillover impacts of Middle East disruptions on global construction material price and supply. Also, Allen (2020) highlights the worldwide effects of political instability on the construction industry in "Geopolitical Impacts on the Future of Construction." Country risk and uncertainty in oil-rich regions, particularly in the Gulf, have been shown to have clear correlations with the volatility of transportation costs for heavy chemicals, such as cement, as noted in the article. Allen also stresses the importance for companies to improve their geopolitical risk model practices and overhaul procurement approaches to limit exposure to a single region.

In "Geopolitics and a Cement Strategy", Pavlopoulos (2017) gives a case-focused account of how companies producing cement are becoming actors in geopolitics. He further suggests that firms need to have a "cement strategy" that is not solely economic but also diplomatic and adaptive and able to respond to both regional conflict areas and global climate directives. Pavlopoulos presents an

interesting argument that cement producers typically operate in weak or weak authoritarian regimes, where a democratic vote can instantly undermine state-corporate connections, logistical convenience, and control over resources.

Additionally crucial is Saeed (2025), whose oeuvre in the Asian Review of Political Economy aims to achieve a timely and deeper validation of the effect of Middle Eastern crises—inter alia, the Iran–Saudi Arabia conflict, the Yemen conflict, and Syrian reconstruction—on re-arranging economic ties. Saeed's compelling evidence suggests that such geopolitical shifts are altering the way cement and building materials are transported within the region and beyond, thereby impacting imports in Europe, particularly for countries with Mediterranean coastlines.

Institutional contributions will also increase the literature. The Council on Foreign Relations (2024) provides a valuable overview of educational objectives, both non-lexically and analytically, in "Middle East and North Africa: The Essentials—Regional Politics," which describes the intertwining of politics, trade, and development in the region. It demonstrates how trade routes, port access, and political relationships impact Europe's ability to secure stable imports of key construction materials from these markets.

Nejad (2025), covering Modern Diplomacy, narrows in on Iran specifically, discussing how Iran's foreign policy and its shifting position in the post-Assad Middle East could be depicted and how a concentration could impact its erosion of partnerships and export prospects. His essay, "The Future of Iran's Foreign Policy in the Post-Assad Middle East Complex Geopolitics," ties Iran's isolation, caused by US-led Western sanctions, to its turn toward non-Western allies, such as China's Belt and Road Initiative. Nejad suggests that these macro-changes could, over time, realign Iranian cement exports to Asia and Africa, further marginalising its role in the European market but also subjecting Europe to secondary market volatility.

The Clingendael Institute's 2022 report, "The Geopolitics of Regional Conflict," offers a consolidated view of Middle Eastern instability for the period 2010–2021. The report details each of the strategic choke points—the Strait of Hormuz and the Bab el Mandeb Strait—that bear on shipping lanes for bulk commodities. These insights are crucial for understanding how even a small armed conflict can escalate into a supply chain crisis for Europe's construction industry, as hostage shipments, stalled shipments, high insurance costs, and uncertainty in sourcing timelines all become factors.

There is a common thread that runs through these sources, and that is that European dependence on Middle Eastern cement is no longer just an economic issue; it has become a strategic and resilient issue. This change, of course, amplifies the exposure to external shocks, especially those resulting from unstable geopolitical regions.

Individually, the research tells a story: the cement-and-concrete-based construction business has an inherent vulnerability to geopolitical shocks. Iraq's supply routes from the Middle East and Iran are particularly vulnerable due to the dual pressures of internal conflict and geopolitical tensions. On the other hand, the literature suggests that the European construction sector may expect risk management, regional diversification, and strategic policy-making to achieve resilience against external dependencies.

This study aims to investigate the impact of conflict, trade sanctions, and regional instability on the European supply chain, including pricing and project delivery in the construction sector. We decide to find answers to our research questions:

1. How reliant is the European construction sector on cement and concrete imports from the Middle East and Iran?
2. What are the main geopolitical events disrupting cement trade from these regions?
3. How do such disruptions affect pricing, timelines, and project feasibility in Europe?
4. What strategies have European stakeholders implemented to mitigate these impacts?
5. What policy measures can enhance the resilience of the European construction material supply chain?

3. Data and Methodology

We used thematic analysis to explain the impact of geopolitical issues in the Middle East and Iran on the European cement and concrete supply chain. The topic is interdisciplinary, specifically dealing

with international relations, trade economics, and construction materials; therefore, a multi-activity data strategy was employed.

The analysis was performed using academic databases, including Scopus and Web of Science. These databases provided access to scholarly work in political science, international trade, construction management, and regional studies. A search was made, using examples such as "geopolitical risks," "cement import," "Iran sanction," "Middle East conflict," and "European construction supply chain." etc. The search was limited to articles published between 2015 and 2025 to ensure that the literature reflects the most recent geopolitical changes and their significance in the contemporary European construction context. Digests were only to peer-reviewed sources or institutional publications of proven academic standing to sustain analytical thoroughness. Articles like Charles (2023), Allen (2020), and Saeed (2025) initially explored long-range views of how instability in the Middle East and realignments are being linked to crucial discussions in the construction supply chain.

Supporting the literature review, numerous secondary data sources were analysed to measure quantitative trends and insights within cement and concrete production, imports and trade dependencies (Mostert et al., 2022). Eurostat, the statistical office of the European Union, was essential for gathering country data on cement production, import-export balance, and demand growth at the country level. Additional information from the European Cement Association (CemBureau) and the World Cement Association, which are associated with the industry, includes civic intensity wake-up, regional constituent malt abilities, and the carbon encyclical pressures associated with adverse domestic access and own constraints.

Data from international trade databases, including the UN and the International Trade Centre (ITC), can be used to identify cement imports from the Middle East and North Africa (MENA) region to Europe, as reported by Poolsawad et al. (2023). These datasets have been particularly useful for analysing changes in source countries over the past decade. For example, Ankara-based Turkey has become the largest non-EU supplier of cement to Europe thanks to its presence and production capacity. However, the roles of Egypt, Algeria, and Saudi Arabia have also increased. Although direct imports from Iran remain small due to international sanctions, Iran's latent production potential and its strategic geographical location make it a key player in the wider MENA supply chain (Zhang et al., 2021).

Changes in regional trade patterns, as well as indirect trade patterns, also contribute to Iran's influence. However, its role remains marginal mainly as long as current sanctions regimes remain in place. Trade data in this research also include other relevant government, geopolitical and regulatory documents, such as sanctions records from the US Treasury Department's Office of Foreign Assets Control (OFAC) and the EU Sanctions Map (Argeime López-Malest et al., 2024). This documentation was key to studying the common and implicit restrictions imposed on all Middle Eastern companies – especially on Iranian exporters. Sanctions not only hinder the legality of trade but also affect risk perceptions and premiums, as well as access to international banking – factors that influence supply chain decision-making in the European construction sector.

For a regional perspective and geopolitical analysis, reports and policy papers from international forums such as the Council on Foreign Relations (CFR) and the Institute for Modern Diplomacy (Caro et al., 2023) were utilised. These sources provided helpful insights into maritime security, conflict escalation and political differences that affect trade infrastructure and readiness for the vault. The closure of the Suez Canal in 2021 following a blockade or ongoing tensions in the Strait of Hormuz and the Bab El-Mandeb Strait is a warning sign of the fragility of the transport routes for bulk construction materials to Europe. The data obtained were, therefore, multidimensional in nature, encompassing both qualitative and quantitative aspects. It provided a comprehensive view of production capacity, trade dependencies, political obstacles and regional instability that encompasses the entire European cement and concrete supply chain.

4. Results

4.1 Impact of Geopolitical Tensions on Supply Chains

The results of the analysis by Erixon et al. (2022) suggest that geopolitical pressures in the Middle East and Iran have significantly and measurably strengthened the logistics of cement and concrete supply chains in the European construction industry. This impact is reflected in both short-

term trade disruptions and long-term changes in procurement patterns and production organisation. The findings utilise multiple data sources – case-based evidence and statistical records – to demonstrate how conflict zones, sanctions regimes, and diplomatic reconfigurations have transformed the import landscape of construction materials into Europe.

Perhaps the most striking illustration of geopolitical disruption was the 2021 blockade of the Suez Canal, which stranded a container ship and then prevented shipping for six days on one of the world's busiest shipping lanes (Fattouh et al., 2021). Although not the conflict itself, it is a case in which it was clear how much European supplies were exposed to bottlenecks in the most politically tense regions. The canal carries around 12% of world trade. Although loose limestone is likely to be transported in bulk, many related materials, including clinker and by-products, also pass through the canal, as noted in Horák (2022). In southern European countries, cement imports fell by 8.3% in the second quarter of 2021 compared to the previous quarter. This decline is observed in this isolated case, as reported by Eurostat. Transport rates also temporarily increased sharply, putting additional pressure on importers and construction companies who were already experiencing material shortages after the pandemic.

In a more persistent and politically tense situation, the change in US sanctions against Iran in 2018 – following the Trump administration's withdrawal from the Joint Comprehensive Plan of Action (JCPOA) – had both direct and indirect impacts on cement flows in the region (Häfner et al., 2023). Iran, once the world's tenth-largest cement producer, had limited export opportunities as the flow of financial transactions and insurance for Iranian trade was halted. As European businesses were not bound by US sanctions, secondary sanctions had the effect of discouraging European importers and logistics providers from withdrawing and being neutral towards Iranian supplies (Doraj and Blanchard, 2020). Although Iran had relatively low levels of direct exports to Europe before 2018, Iran's involvement in its neighbours' supply chains and its ability to influence regional prices from afar have influenced European purchasing strategies. Cement exports from Iran fell by almost 40 per cent between 2017 and 2019, according to data from the International Trade Centre (ITC) (Meidan et al., 2023). At the same time, European importers have turned to alternative Middle Eastern sources, notably Turkey and Egypt, which have increased production to cover the deficit.

The course of the Syrian civil war is another excellent illustration of the disruption caused by conflict. Before the war, Syria had a small cement industry that supplied parts of Lebanon, Jordan, and Iraq. However, the destruction of domestic infrastructure not only eliminated Syria as a source but also altered regional trade flows, causing port congestion and increasing import demand from external trading partners in neighbouring countries (Neset et al., 2023). European companies that were contractually obligated to carry out reconstruction work in the Levant suffered "severe delays" and "cost overruns" due to supply chain problems, security concerns, and insufficient local manufacturing capacity. Moreover, the fact that militant groups have taken control of cement plants – as in the Lafarge scandal, in which the French cement manufacturer was accused of providing financial support to fighting organisations to maintain operations in Syria – highlights the ethical and operational difficulties that arise when operating in conflict areas (Pochat, 2023). These risks are not only reputational and legal risks for European businesses but also operational disruptions that can be transmitted through the supply chain.

The impact of these events can also be seen in the statistics on cement supplies to the EU. Eurostat data from 2015 to 2023 show that domestic cement production in the EU has remained relatively stable in the meantime, while the respective share of imports from third countries has increased from 6.7% to 11.2% of total cement consumption. Notably, countries such as Spain, Italy and Greece have seen cement imports exceed 30% since 2018 as they sought to keep their domestic producers under the stricter regulations of the EU Emissions Trading System (ETS) (Azad, 2024). This increase in outsourcing has increased exposure to external political risks. Relying on countries such as Turkey, which has experienced significant political and economic changes, including currency devaluation and the rise of authoritarianism, creates an additional layer of uncertainty.

Another quantifiable consequence of the impact of geopolitical tensions and escalating costs on the supply chain is that, based on construction cost indices published by Euroconstruct and the OECD, the prices of cement and concrete in Europe increased by 19% between 2020 and 2023. Part of this increase can be attributed to inflation following the COVID-19 pandemic and rising energy prices. However, a regional case study (Bhattarai and Yousef, 2025) shows that imported cement exhibits

higher price volatility. For example, the resumption of hostilities between Israeli forces and Iranian-backed militias in Syria in 2022 triggered higher shipping and insurance fees in the Eastern Mediterranean. Shipping companies then passed on the burden to importers, who then shifted it to the construction industry.

The data also shows that corporations, on the other hand, are addressing these risks by expanding their sourcing policies. There is a growing trend among European companies to invest in domestic recycling of construction waste, aiming to reduce their reliance on imported clinker. The shift that has occurred here aligns with EU sustainability goals and represents a step in regional geopolitical risk management (Biazzi, 2022). Meanwhile, companies have come to rely on politically stable, albeit geographically distant, countries, including Vietnam and Indonesia, which have increased shipping distances and, consequently, carbon emissions. This trade-off between strategic resilience and environmental performance presents a new challenge for policymakers and business leaders in the construction industry.

Another issue is the key vulnerability created by narrow maritime transport hubs. All lie at the heart of the global supply chain for bulk construction materials from the Middle East to Europe. Disruptions to these routes – whether through combat, piracy or sabotage – have the most significant impacts anytime, anywhere, with their ripple effects on schedules and prices (Pradhan, 2020). For example, the Horthy attacks on merchant ships in the Red Sea in 2023 resulted in temporary diversions of shipping, leading to long-term delays in deliveries and increased shipping prices. Even short-term closures in these corridors can hinder large-scale infrastructure projects across Europe, particularly those reliant on just-in-time supply chains.

Research findings indicate that geopolitical uncertainty has not only disrupted short-term logistics but also led to permanent changes in the supply of cement and concrete in Europe (Şahmaran et al., 2020). The shift towards diversification, localisation, and technical innovation in construction materials can be partly attributed to these disruptions. However, such measures have not led to an accelerated elimination of the conflict but rather to its displacement to other regions and channels. The ongoing conflict in the Middle East and the ongoing uncertainty around Iran's integration into the global system mean that Europe's exposure to geopolitical supply chain risk is likely to be long-term.

4.2. Trade Policy and Sanctions Analysis

The impact of trade policies and international sanctions on the European construction sector – particularly regarding imports of cement and concrete from the Middle East and Iran – is vast, multi-layered, and closely linked to political issues (Alshareef, 2023). This section critically examines the function of trade-related interventions – particularly the sanctions imposed on Iran – and how they have reorganised material objects, distorted markets and worsened procurement strategies in Europe. The analysis also examines how more general trade agreements and tariff regimes have influenced the availability, price, and sourcing lists of construction materials, demonstrating that the political economy and the resilience of the construction industry are intertwined and inseparable.

Iran is a prime example of how targeted sanctions can yield unintended consequences, often with a profound impact. With a historical production of over 80 million tons per year, Iran was once one of the world's leading cement producers, boasting a competitive advantage in providing affordable cement to markets in the Middle East, Central Asia, and, to a lesser extent, Eastern Europe (Stošić, 2023). However, the imposition of US sanctions following the withdrawal from the Joint Comprehensive Plan of Action (JCPOA) in 2018 drastically disrupted Iran's participation in world trade. Although the European Union initially sought to maintain its presence at the negotiating table on the JCPOA, the risk of secondary US sanctions ultimately persuaded European companies to refrain from trading with Iranian products, including cement (Valadbaygi, 2025). This discreet withdrawal was not due to the EU directive on the embargo on Iranian cement but rather a courtship indirectly caused by the risks of dealing with sanctioned parties or limiting compliance in overlapping jurisdictional frameworks.

The real effects of these sanctions have been severe. In 2016, Iranian cement exports were recorded at over 18 million tonnes, which have fallen sharply in the following years. As of 2020, total exports have declined to just under 11 million tonnes, with almost no imports to Europe (Acevedo and Lorca-Susino, 2021). It has led to a supply deficit in regional markets, and countries such as Iraq, Afghanistan, and Syria have sought alternative sources from Middle Eastern producers. This shift in

demand has strained existing exporters such as Turkey and Egypt, whose surplus production has increasingly been directed to these nearby markets, further tightening the availability of cement for Europe.

The knock-on effect has also been reflected in pricing. Although European countries were not heavily dependent on large volumes of Iranian cement, the collapse of a major regional power led to a shift in supply and demand dynamics across the MENA region (Akhtar et al., 2024). Clinker and bulk cement prices, especially in Mediterranean ports, also became more volatile. Export-oriented firms in Turkey, Egypt, and Algeria have begun to experience an increasingly volatile pricing environment, primarily due to higher freight demand and longer delivery times resulting from diverted trade (Alzawawy, 2022). Additionally, increased pressure on Turkish and Egyptian producers led to lower export volumes for EU consumers, favouring more gradual local partnerships.

The shift in supply was only one aspect of the broader impacts of sanctions on logistics, insurance, and financing. Shipping companies were wary of entering Iranian ports or transporting goods diverted from their routes due to concerns about losing insurance coverage or disputes with US authorities. They began to withdraw their support for processing payments or issuing letters of credit covering operations from Iranian companies, making trade impractical despite the complete absence of an EU trade embargo. This financial exclusion had the deterrent effect not only of banning Iranian cement from European sources but also of reducing the competitiveness of the entire market and diversifying supplies. In addition, the sanctions regime extended to the broader logistics infrastructure of Iranian operations, including the diversion of port use, customs protocols, and multiple trade routes. China's Belt and Road Initiative (BRI), a transcontinental project in development, has increasingly highlighted the country's economic isolation (Wrobel, 2023). European suppliers that sought to expand their import techniques by relying on inland routes or a combination of shipping and rail through Iran had to reassess these strategies due to operational challenges and concerns about sanctions enforcement.

In addition to sanctions, European trade policy instruments have also significantly affected the supply situation for construction materials. The implementation of the EU's Carbon Border Adjustment Mechanism (CBAM), which aims to redress the uneven playing field faced by domestic producers operating under strict emission controls and lower published limits that competing producers from other countries continue to apply, will soon shake up the balance of cement imports (Alzawawy, 2022). Cement is among the first sectors to be affected by the CBAM; it imposes a carbon tariff on the level of emissions-related tariffs on imported goods. Although this policy is environmentally friendly, it functions as a trade barrier by imposing environmental costs on imported cement from countries without an equivalent carbon pricing regime – specifically, countries in the Middle East and North Africa.

The result of this accumulation of trade policies, sanctions, and diplomacy is high volatility and fragmentation. European construction companies are increasingly exposed to international political risks, including those related to procurement methods (Erixon et al., 2022). Importers must undoubtedly consider costs and logistics, as well as the legal and other aspects of purchasing from specific regions. For smaller construction companies, which have limited access to the legal framework and geopolitical lobbying knowledge of multinationals, this complexity presents an obstacle, leading them to more expensive suppliers with lower risk and domestic production that may not meet production requirements or be cost-effective.

In this regard, we reflect the growing European interest in autonomy in the acquisition of materials – a reflection of ambitions in energy policy – which is all the more understandable. Policymakers need to consider how to mitigate risk not only through diversification but also by investing in low-carbon cement substitutes, recycling technologies, and reducing dependence on high-carbon imports. While such strategies are promising, they require time and significant financial investment. Meanwhile, construction remains vulnerable to political instability in its trading partners.

5. Discussion

This research reveals an intense and complex relationship between geopolitical events in the Middle East and Iran and disruptions in the supply of materials to the European construction industry. Cement and concrete, as essential components of infrastructure, and their dependence on the supply chain are good indicators of the vulnerabilities posed by international political instability (Stošić,

2023). The empirical evidence presented in the results section – from import statistics to cost volatility and case studies – tells a clear story about the growing shortages and costs of logistical uncertainty: The higher the political tensions in key supply regions, the bigger the wave that Europe once again has no access to, except for the fear that it is too small and therefore has to look for help everywhere. It is especially true when events occur in geopolitically significant areas or when countries that control Europe's external cement supply are involved.

The observed relationship becomes even more pronounced when there is an increase in conflict or the imposition of sanctions. The changes that have occurred, such as the re-imposition of sanctions on Iran in 2018, have been consistent with significant shifts in the behaviour of European suppliers, increased inflation in import costs, and alterations in regional trade flows (Valadbaygi, 2025). Additionally, maritime disruptions in the Suez Canal and the Red Sea have had a direct impact on delivery times and shipping rates. These political events are not isolated, but they exacerbate previous structural challenges in the EU as a market, such as carbon price pressures, limited supply capacity, and high demand in post-pandemic situations, thereby increasing overall machine heterogeneity.

Conceptually, these results are consistent with the existing literature, which has long argued that the construction supply chain is highly vulnerable to external shocks due to its high dependence on the transportability of bulk goods and its susceptibility to time-dependent procurement, as well as exposure to fuel and transportation costs (Wrobel, 2023). For example, Allen (2020) notes that construction is particularly prone to stubborn resistance to rate adjustments among industries due to its rigidity when projects are advanced and long. Pavlopoulos (2017) also points out in the context of coordination situations in global supply chains that cement logistics, unlike high-value manufactured goods, cannot easily absorb increased transportation costs that significantly impact final project budgets due to their low value-to-weight ratio. These vulnerabilities have been demonstrated in practice during recent Middle Eastern crises, corroborating the literature that construction supply chains are both economically and geopolitically exposed.

Furthermore, the findings confirm Charles (2023), who outlines a direct relationship between regional instability and the volatility of construction material intensity in the Middle East and Africa (MEA), with an impact that is not limited to the MEA but also extends to Europe. The geopolitical embeddedness of construction material flows – whether they involve individual countries or countries with secondary linkages, such as those in the Middle East – also means that even unintended proximity in conflicts or sanctions has measurable effects on distant markets. For example, the reallocation of surplus cement from Turkey and Egypt to more proximal reconstruction projects following the Syrian and Yemeni wars reduced excess supplies in the European market, consistent with the supply-side shift theory in international trade economics.

Where this research differs is in applying this theoretical understanding to the specific case of the EU construction industry within the context of specific regulatory frameworks, such as the EU CBAM, and evolving market practices. While previous literature has conventionally treated geopolitical instability and trade volatility as country-specific shocks or unpredictable add-ons, this appears to lead to a deeper institutionalisation of geopolitical risk into the structure of the European construction supply chain. It represents a shift from episodic disruption to a persistent state of uncertainty that necessitates transformation at the sector level.

5.1. Strategic Responses by European Firms

In response to these multifaceted challenges, European construction companies have begun implementing several key strategic measures to mitigate their vulnerability to geopolitically driven disruptions in the supply of materials (Azad, 2024). However, the most significant of these is probably the differentiation of supply sources. In response, many European companies are now seeking to increase their supply base from countries outside the traditional Middle East and North Africa (MENA) region and to minimise their dependence on a larger number of countries to avoid the risks of heavy dependence on relatively small countries – countries that are usually located in a geopolitically turbulent zone. For example, Eurostat data recently showed an increase in imports from Southeast Asia, specifically Vietnam and Indonesia, where companies are attempting to reroute goods away from the chaotic Mediterranean routes (Bhattarai and Yousef, 2025). Although alternatives to these means of transport involve higher transport costs and longer delivery times, they are considered more sustainable in the long term, especially given Europe's recent focus on supply chain sustainability. In

addition to geographical diversification, companies are currently investing in alternative materials and technologies to reduce their dependence on traditional forms of cement. The injection of expansion agents, which involves recycling construction and demolition waste (CDW) into second-generation products (secondary aggregates), on the one hand, and the introduction of low-carbon cement substitutes, such as fly ash, slag, and binders, on the other, are being developed (Biazzi, 2022). These innovations align with the EU's climate ambitions, as outlined in the EU-CVI, while also diversifying geopolitical risks by internalising a larger part of the supply chain within the national territory. However, these changes require significant investment in studies, infrastructure, and regulatory adjustments, making them a medium to long-term option, neither short-term nor easy.

Another strategic response is logistical adaptation. The disruption of major shipping routes, such as the Suez Canal and the Red Sea, has forced companies to reduce their dependence on transport and explore multimodal logistics that involve rail, road, and inland waterways (Erixon et al., 2022). For example, some operators from Central and Eastern Europe are starting to use land routes through the Caucasus or Central Asia; however, they are limited by capacity and infrastructure. In addition, more advanced digital logistics platforms are being introduced to better support forecasting, real-time shipment tracking and any delays that geopolitical tensions may cause.

Some of the largest construction companies and cement importers are also actively adopting vertical integration strategies – they have control over otherwise independent upstream and downstream suppliers to try to reduce external risks (Fattouh et al., 2021), (Horák, 2022). This strategy has become particularly attractive in the context of CBAM, as companies seek to manage the carbon content of their supply chains to remain competitive in an increasingly volatile regulatory environment. Production options within the EU or in neighbouring stable countries offer predictability of cost structures and mitigate any financial risks caused by tariffs, sanctions, or trade disruptions resulting from conflicts.

At the global policy level, industry trade associations such as Cembureau are calling for greater EU-level harmonisation in the provision of critical construction goods, including the creation of strategic storage facilities, strengthened trade agreements with stable supplier countries and fast-tracking permits for domestic low-carbon cement plants (Häfner et al., 2023). Green corridors, secure and decarbonised supply routes, and engaging in trade only between Europe and preferred partners would lead to increased interest in climate and security benefits.

Although these efforts are being made, the impact of strategic responses varies widely across firms and sectors. Large multinational suppliers, global supplier networks and deeper capital buffers can absorb shocks and changes. On the other hand, many small and medium-sized enterprises (SMEs), which comprise the majority of the industry, lack sufficient financial and logistical resources to easily switch suppliers or materials (Doraj and Blanchard, 2020). As a result, they remain disproportionately exposed to price volatility, delivery delays and contractual risk. This long-standing gap highlights the need for policy support, industry collaboration and knowledge-sharing platforms that can facilitate access to risk-reduction tools.

Conclusion

We find that the European construction sector will be more resilient to increasing geopolitical turbulence if policymakers adopt a holistic and forward-looking strategy similar to that found by Meidan et al. (2023). The reasons are as follows. First, there is an urgent need to create strategic stocks of materials, especially cement and clinker – a kind of energy reserve – to help mitigate short-term supply shocks resulting from sudden geopolitical events. These stocks could be coordinated at the EU level to ensure a fair distribution of shares and to avoid the risk of resources being dependent on a single supplier or location. Secondly, more investment should also be made in newly built domestic low-carbon cement plants. It can be achieved through subsidies for green innovation, facilitating the permitting of sustainable cement plants and offering incentives for the use of alternative materials – such as recycled aggregates as binders (Neset et al., 2023). These measures not only increase supply chain autonomy but also support the EU's decarbonisation objective. Third, trade diversification should be sought through new or more substantial commitments to politically stable countries that are less dependent on the Middle East and North Africa. Bilateral agreements could include provisions to support logistics cooperation, compliance with emissions regulations, and mechanisms for dispute resolution. Finally, international cooperation, particularly through multilateral institutions such as the

WTO and regional trade bodies, should focus on building robust and transparent trade practices. It includes financing protected shipping lanes, mutual digital trading platforms, and joint conflict response plans to protect cargo and the flow of materials.

Although this study presents a rigorous qualitative analysis, as it relies on secondary data and thematic analysis, conclusions about causality are not possible, which aligns with Alzawawy (2022). Furthermore, such studies are likely to become quickly outdated or context-specific due to the rapid changes and developments in geopolitical events.

Future research should focus on real empirical case studies, especially those that include interviews with industry insiders and policymakers, to gain a deeper understanding of how firms manage geopolitical risks. Additionally, we propose conducting quantitative modelling of supply chain disruptions and price elasticity in the context of conflicts. Chain-based supply tracking and predictive analytics in geographically exposed zones will strengthen the sector's strength. Furthermore, examining the role of emerging powers such as China and India in shaping global cement flows provides a more global perspective on supply chain changes in a multipolar geopolitical context.

Progress in the Competitiveness of the Slovak Republic in the Context of Sustainability

***Elena* Širá**[1,*]

[1] University of Prešov in Prešov, Faculty of Management and Business, Department of Economics and Economy, Konštantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: The Sustainable Development Goals (SDGs) play a key role in enhancing a country's competitiveness by aligning economic growth with social and environmental sustainability. Incorporating the SDGs into national policies promotes innovation, attracts investment and improves overall economic resilience. There is a known positive correlation between the implementation of the SDGs and national competitiveness. The relationship between the various competitiveness indices and the SDGs suggests that sustainable practices can improve a country's global position.
Purpose of the article: The main aim of the paper is to investigate the progress in the selected SDGs goals in Slovak Republic. The analysed period is 10 years. According to main aim, there was set the research questions: What are Slovakia's strengths and weaknesses? Where has the most significant progress been made?
Methods: To solve these questions and investigate Slovakia's progress, we used the methods of analysis and synthesis, correlation, and other methods of descriptive statistics. For complex calculations, we used the Statistica software.
Findings & Value added: At the conclusions, progress in the competitiveness of the Slovak Republic were identified. There were set challenges and risks according to the SDGs for Slovakia, which must be considered to improve the current situation in the competitiveness.

Keywords: Sustainable development goals, Agenda 2030, Social dimension, Environmental dimension, Economic dimension

JEL classification: J11, O15, O44

1. Introduction

High competitiveness is now one of the main prerequisites for national economies to increase GDP per capita and to grow welfare, i. e. to improve the level and conditions for health, social protection and living standards. One of the classic definitions of competitiveness specifies it as the ability to produce goods and services that meet the demands of international markets while maintaining high and sustainable levels of income, or, more generally, the ability of regions to generate relatively high levels of income and employment, even when exposed to external competition. Competitiveness at a macro level, it should be noted, for example, at national competitiveness, which is associated with improved living standards, is determined by raising productivity that creates the competitive advantage of a country in international trade (Boikova et al., 2021).

Increasing the competitiveness of EU countries can be achieved by strengthening the regional development of EU regions and closing regional gaps. This is the focus of various EU initiatives aimed at raising up EU economies to a higher level, i.e. Europe 2020, Agenda 2030 and others. It should be noted that sustained, inclusive and sustainable economic growth is one of the Sustainable Development Goals to be achieved by 2030 under the 2030 Agenda, which is the work of the United Nations (Di Vaio et al., 2022). Nevertheless, the concept of competitiveness is constantly evolving, as are the drivers or determinants of competitiveness (Boikova et al., 2021).

2. Theoretical background

Sustainable development is a widely accepted concept. It is defined as development that meets the needs of the present without compromising the ability of future generations to meet their own needs (Carpentier & Braun, 2020). This definition underscores the fundamental balance between the three interrelated dimensions:

- environmental,
- social,
- economic (Carew & Mitchell, 2008).

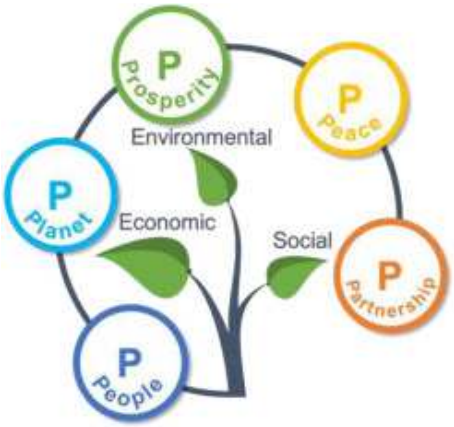

Figure 1. Five pillars 5Ps
Source: Khajuria et al. (2022)

Mentioned dimensions are structured around five pillars (5Ps) - people, planet, prosperity, peace, and partnership with the aim of shifting the world onto a sustainable and resilient development path and leaving no one behind. The first pillar People targets to end poverty and hunger, the second pillar Planet defines to protect the planet from degradation, the third pillar Prosperity ensures that all human beings can enjoy prosperous and fulfilling lives, the fourth pillar Peace dictates to foster peaceful, just, and inclusive societies and the fifth pillar Partnership helps to establish a network and mobilize the means to implement this agenda (Khajuria et al., 2022).

Environmental Sustainability - this dimension focuses on the conservation and responsible management of natural resources and ecosystems (Piwowar-Sulej et al., 2023). It aims to ensure the long-term availability of natural resources and the health of the planet for future generations (Tóthová & Heglasová, 2022), (Khajuria et al., 2022).

Social sustainability - this pillar seeks to promote inclusive societies, reduce inequalities and ensure long-term well-being and equity for all people, thereby maintaining social cohesion (Andrade et al., 2020). It addresses critical issues such as poverty, discrimination, social exclusion, lack of access to basic resources (such as education and health care), and the prevalence of insecurity and conflict.

Economic sustainability - this dimension focuses on creating long-term economic growth and development (Ricciolini et al., 2024) without depleting natural resources or undermining social equity, thereby not compromising the ability of future generations to meet their needs (Diaz-Sarachaga et al., 2018). It promotes a healthy balance between economic expansion and responsible use of resources.

Sustainability, encompassing environmental protection, social well-being and economic viability, is no longer a peripheral issue but increasingly recognized as a fundamental competitive advantage for nations and societies (Sorooshian, 2024). The Sustainable Development Goals (SDGs), adopted in 2015, provide a comprehensive and universal framework to address interconnected global challenges, from poverty and hunger to climate change and biodiversity loss, guiding nations towards sustainable development (Montanari et al., 2020), (Adamišin et al., 2022). At the national level, commitment to environmental sustainability, including internalizing the costs of pollution and responsible natural resource management, drives efficiency, reduces waste, and stimulates innovation. In total, 17 of these are specified, each with a different number of indicators to quantify it.

Figure 2. Sustainable Development Goals
Source: Focus 2030

The SDGs are not just a set of targets, but represent a holistic, integrated performance metric for national well-being and long-term viability, transcending the limitations of GDP as a single measure of progress (Montanari et al., 2021). Achieving these goals requires a systems approach (Carpentier & Braun, 2020), where progress in one area can create multiplier effects in other areas, strengthening a country's overall resilience and competitive position.

3. Methods

The main aim of the paper is to investigate the progress in the selected SDGs goals in Slovak Republic. To achieve the main objective, we have set the following subsidiary objectives:

- to analyse the development of Slovakia in selected indicators,
- to compare the development of Slovakia with the EU 27 average,
- to compare the development of Slovakia with the average of the countries, that joined the EU in 2004 (EU 2004) – it is the year, that Slovakia also joined the EU,
- predict the trend of development of Slovakia for the next period,
- identify the relationship between competitiveness and selected SDG.

According to main aim, there was set the research questions:

- RQ1: What are Slovakia's strengths and weaknesses?
- RQ2: Where has the most significant progress been made?
- RQ3: Do the fulfilments of SDGs affect the competitiveness?

To answer these questions, we have chosen to compare Slovakia with the EU 27 average as well as with the average of EU 2004. The EU 2004 countries were chosen, because they joined the EU in the same year as Slovakia, so they had similar conditions and comparable levels of economics at that time. Therefore, we were interested in their progress and whether any differences have developed between the countries. To answer the RQ3 we have chosen the EU 2004 countries and GSCI index.

The GSCI index was selected to assess the competitiveness area. This index was chosen because it also takes into account the area of sustainability. Also because results are also available for the years 2023 and 2024, so it is possible to compare them with the SDG results achieved in that period (not all selected SDGs had data available for 2024).

The GSCI Index (Global Sustainable Competitiveness Index) from Solability is a comprehensive index that measures the sustainable competitiveness of countries. It was first published in 2012 and serves as an alternative to traditional metrics (Almos, 2022). The GSCI assesses the sustainable competitiveness of countries based on more than 200 quantitative indicators The indicators are grouped into six core pillars that define the competitiveness of a national economy:

- Natural Capital,
- Resource Efficiency,
- Social Capital,
- Intellectual Capital & Innovation,
- Economic Sustainability,
- Governance Performance (Solability, 2025).

The analysed period is 10 years. We have used the methods of analysis and synthesis, as well as prediction using linear trends. Among the SDG targets we chose 6 indicators. For each sustainability dimension we set 2 indicators. These, as can be seen below, are the content of SDG 1, SDG 8, SDG 12, SDG 13. Selected indicators within the SDG dimensions:

- Social
  - *Persons at risk of poverty or social exclusion (SDG_01_10),*
  - *In work at-risk-of-poverty rate (SDG_01_41).*
- Environmental
  - *Circular material use rate (SDG_12_41),*
  - *Domestic net greenhouse gas emissions (SDG_13_10).*
- Economic
  - *Real GDP per capita (SDG_08_10),*
  - *Employment rate by sex (SDG_08_30).*

4. Results and discussion

In the following section we present the results from the analyses of the selected indicators. We will look for answers to RQ1 and RQ2.

Slovakia has maintained a significantly lower percentage of people at risk of poverty or social exclusion compared to the EU27 average over the 2015-2024 reference period. In each year, the difference has been substantial, ranging from almost 7 percentage points in 2015 to more than 6 percentage points in 2024. From 2015 until the Covid-19 pandemic, both in Slovakia and in the countries that joined the EU in 2004 (EU 2004), there was a decline and then, from 2020 onwards, an increase in the number of people at risk of poverty. Based on a linear trend, we expect a slight increase in this indicator for Slovakia in the next period as well.

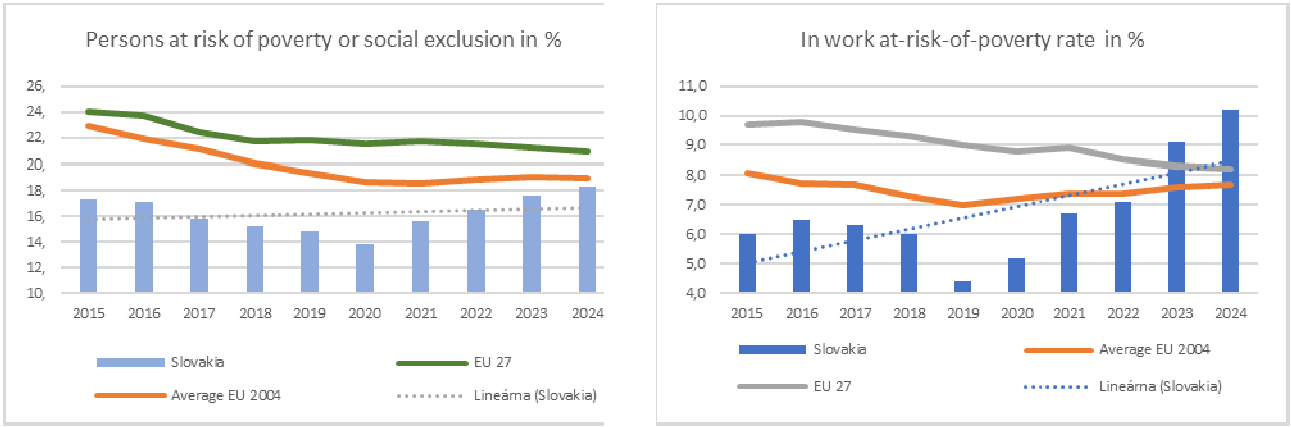

Figure 3, 4. Selected SDG goals from social dimension
Source: own processing (2025)

Between 2015 and 2022, Slovakia had a significantly lower risk of poverty after social transfers compared to the EU27 average. The lowest value was reached in 2019 (4.4%), which was almost half the EU27 average. From 2022 onwards, the situation in Slovakia started to worsen. From 7.1% in 2022, the risk of poverty rate rose to 9.1% in 2023 and to 10.2% in 2024. This increase is significant and in 2024 Slovakia surpassed the EU27 average (8.2%). Similarly to the EU27, Slovakia has

outperformed the average of EU 2004 compared to the EU average in the years 2023 and 2024, suggesting that the effectiveness of social transfers in combating poverty in Slovakia has declined in recent years, or the sensitivity to poverty risks has increased.

Slovakia shows a very positive trend in the use of recycled materials. At the beginning of the reporting period (2015 - 2018), Slovakia's recycling rate was well below the EU27 average. It was even lower than the EU 2004 average (6.6%). After 2019, the situation has changed dramatically. Slovakia has significantly surpassed the EU 2004 average and has moved closer to the EU 27 average. In 2022, Slovakia has peaked with 11.5% equal to the EU 27 average. Although it has slightly declined in 2023, the overall development is very encouraging and indicates a shift towards a circular economy.

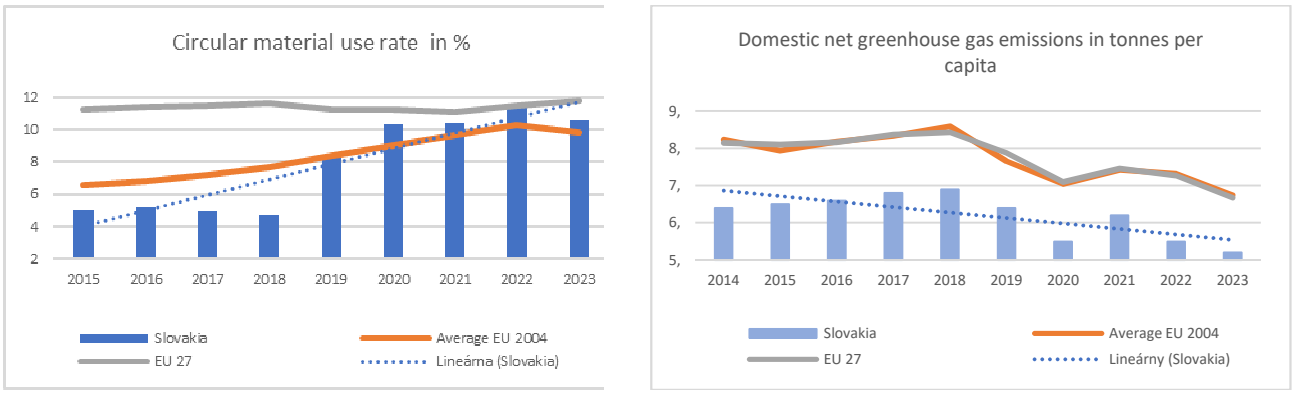

Figure 5, 6. Selected SDG goals from environmental dimension
Source: own processing (2025)

The development of emissions in Slovakia was quite volatile in the analysed period. While emissions were slightly lower in 2014 - 2015, there was a significant increase in 2018 and since then they have remained at a higher level, also with slight decreases. However, the overall trend for Slovakia is downwards, which is a positive in this situation. There has also been a fluctuating trend in this indicator in the EU27 and EU 2004 averages. Slovakia basically followed the development line of the whole EU.

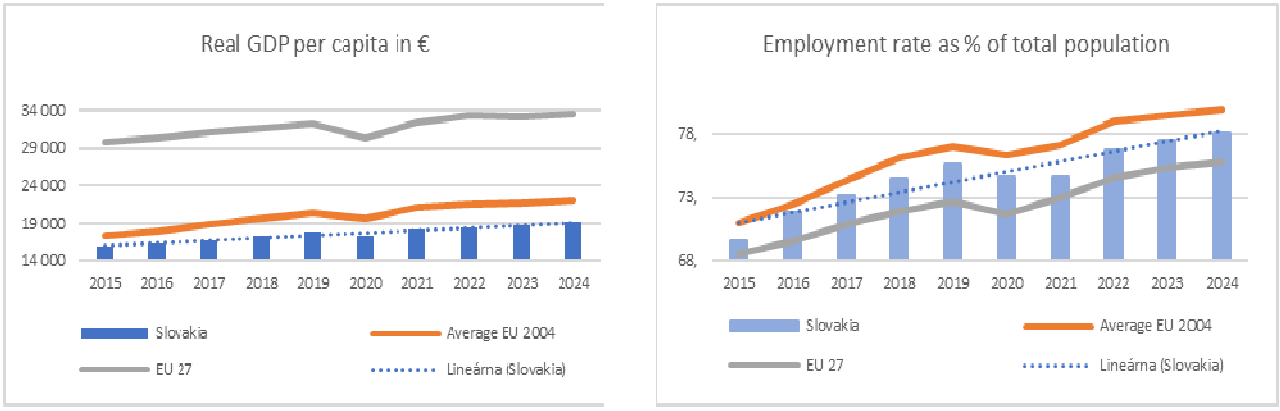

Figure 7, 8. Selected SDG goals from economic dimension
Source: own processing (2025)

GDP per capita in Slovakia has shown an increasing trend in the period under review. Despite a slight decline in 2021, probably due to the Covid-19 pandemic, GDP per capita growth accelerates again in 2022 - 2024. Overall, GDP per capita in Slovakia increases significantly from € 17,990 in 2015 to € 25,380 in 2024. Throughout the analysed period, GDP per capita in Slovakia has been significantly lower than the EU 27 average as well as the EU 2004 average. Although Slovakia shows growth, the gap in absolute terms remains significant. In 2024, GDP per capita in Slovakia was approximately € 8,150 lower than the EU 27 average.

The employment rate in Slovakia shows a clear and stable upward trend over the analysed period. From 59.2 % in 2015, it has increased to 69.5 % in 2024, indicating an improving labour market situation and increasing labour force participation of the population. The EU 27 average also shows an increasing trend in employment rates. Developments in Slovakia, and in the EU 27 and EU 2004 averages follow the same trajectory, with a slight decline in this indicator in 2020. Overall, the employment rate in Slovakia is at a higher level than in the EU.

We examined competitiveness on the basis of the GSCI index. We chose only EU countries to analyse which of the economies was the best ranked in 2023.

Figure 9. GSCI score in EU in 2023
Source: own processing (2025)

As can be seen from the Figure 9, the best are Nordic countries. With the highest score of 59.6, Sweden came in first place, confirming its position as the leader. Sweden is followed closely by Finland and Denmark, confirming the general trend that the Nordic countries are often at the top of rankings on sustainable development, innovation and quality of life. Estonia, with 56.7 points, is ranked fourth, an excellent result for this Baltic country, which belongs to our EU 2004 group. Slovakia, with a score of 51.9, is in the bottom third of the analysed countries. It was overtaken by countries such as the Czech Republic, Slovenia, Lithuania, as well as Croatia. This result suggests that Slovakia has opportunities for improvement compared to countries with a similar history or economic development.

To validate RQ3, we used statistical software Statistica to examine the correlation between a country's competitiveness and selected SDG targets. We verified this for the year 2023, because some SDGs had data available only for 2023, on a sample of EU 2004 countries. Competitiveness was represented by the GSCI (score for 2023).

Table 1. Correlation analysis

Variable	Correlations (Spreadsheet1) Marked correlations are significant at p < ,05000	Correlation
	GSCI	
sdg_01_10	0,278726	positive
sdg_01_41	0,049118	positive
sdg_08_10	- 0,32893	negative
sdg_08_30	- 0,12144	negative
sdg_12_41	0,061471	positive
sdg_13_10	0,206341	positive

Source: own processing according to Eurostat and Slobality (2025)

The correlation results suggest that there are only very weak or negligible linear relationships between the GSCI and these particular SDG indicators. A negative correlation was identified for SDG 8

indicators, which formed the economic dimension in our analysis. For the remaining SDGs a positive correlation was identified. The most important finding is that none of these correlations are statistically significant.

Conclusion

Slovakia has maintained a significantly lower percentage of people at risk of poverty or social exclusion in the 2015-2024 period compared to both the EU 27 average and the EU 2004 average. In the second indicator, Slovakia showed a significantly lower risk of poverty after social transfers compared to the EU 27 average at the beginning of the reference period, i.e. 2015 - 2022. From 2022 onwards, the situation in Slovakia started to worsen.

For a deeper understanding of Slovakia's position in selected SDG social targets, it is necessary to analyse the reasons for the recent increase in the risk of poverty after social transfers. These could be factors such as inflation, insufficient valorisation of benefits, changes in social transfer policies or rising unemployment in certain segments of the population. Monitoring these trends and taking appropriate measures will be key to maintaining and improving the social situation in Slovakia.

Slovakia has made huge progress in the use of recycled materials and is rapidly catching up with the EU 27 average. As of 2019, it has also surpassed the EU 2004 average. This positive development indicates a growing awareness and implementation of circular economy principles. Also, in terms of greenhouse gas emissions per capita, Slovakia has better, lower values than the EU 27 average, reflecting the efforts made to reduce the carbon footprint.

Of the economic sustainability indicators analysed, Slovakia performs best in employment. Throughout analysed period, it was higher than the EU 27 average, but still lower than the average of the EU 2004 countries. The trend in this indicator is upwards, which is indicative of a well-adjusted employment policy.

To answer the research questions, we can say that Slovakia is on a good trend in terms of sustainable targets, but the year-on-year increase is still low. Slovakia has the best competitive position in environmental goals. The most striking is the comparison with the average of the EU 2004 countries. Countries that had a similar starting position when they joined the EU are now in different positions and Slovakia is among the weakest of them. Employment in Slovakia is good, but there is still a problem with social targets. It is necessary to identify the causes and work to eliminate the problem areas.

The GSCI provides a clear picture of the relative performance in competitoveness of countries in 2023. It confirms the leading position of the Nordic countries and suggests that Western and Central European countries are in a stable position, while Southern and some Eastern countries have greater challenges ahead. For Slovakia, this means the need to identify specific areas where it is lagging behind comparators and leaders in order to move up in the sustainability and competitiveness rankings.

This research has its limitations. In the future, it is possible to extend the sample of countries to the whole EU 27, or to add a longer time period for the research. Of course, the Covid-19 pandemic also had a significant impact on countries' economies and some countries are still recovering from this crisis today. Therefore, the results may be different and still affected by the negative impact of this pandemic.

In conclusion, nations that strategically integrate the SDGs into their national development strategies are better prepared to achieve long-term competitiveness that is not only economically strong, but also socially just and environmentally responsible.

Abstract

Research Background: In the era of accelerated digital transformation and increasing emphasis on sustainable development, assessing the performance of national economies faces significant challenges. Traditional macroeconomic indicators fail to capture the full complexity of a country's readiness to respond to technological, environmental, and societal changes. Particularly in the context of the heterogeneity among EU-26 member states, there is a growing need for an analytical approach that reflects not only economic output but also the level of digital maturity, the quality of public governance, and the sustainability of development trajectories. Internationally recognized composite indices such as DESI, NRI, and GSCI provide a suitable foundation for multidimensional evaluation that captures both current performance and long-term developmental potential.
Purpose of the Article: The aim of the article is to analyze and compare the level of digital performance, network readiness, and sustainable competitiveness of EU-26 countries during the period 2017–2022 using selected global indices (DESI, NRI, GSCI). The paper further seeks to identify structural relationships between the dimensions of these indices and reveal the key factors influencing national performance in the context of digital and environmental transformation.
Methods: The analysis employed a comparative evaluation of the average scores of the selected indices, along with correlation analysis using Kendall's Tau coefficient. Relationships were assessed between the overall index scores and their individual dimensions/pillars, as well as the interconnections among DESI, NRI, and GSCI.
Findings and Added Value: The results confirm statistically significant correlations between digital performance, network readiness, and sustainable competitiveness. The most influential determinants included digital skills (DESI_DIM_1), digitalization of public services (DESI_DIM_4), and the quality of digital governance (NRI_PIL_3), all of which showed strong associations with social and intellectual capital (GSCI_PIL_3 and GSCI_PIL_4). A moderate correlation was found between DESI and GSCI ($\tau = 0.4439$), and between NRI and GSCI ($\tau = 0.3635$), indicating that countries with more advanced digital and network infrastructures also tend to achieve higher levels of sustainable competitiveness. The comparative evaluation of DESI and NRI highlighted their complementary nature while DESI reflects the current state of digital performance, NRI provides a more strategic perspective on countries' readiness to face digital challenges.

Keywords: Digital Economy and Society Index (DESI), Network Readiness Index (NRI), Global Sustainable Competitiveness Index (GSCI), European countries (EU-26)

JEL classification: O33, O57, F63

1. Introduction

The different levels of competitiveness in different economies, not only within the EU but also elsewhere in the world, are mainly due to differences in the drivers of competitiveness. These factors determine a country's ability to achieve sustainable growth and improve economic welfare. A key

[*] Corresponding author: beata.sofrankova@unipo.sk

question in the relationship between competitiveness and economic growth is which criteria among the main competitiveness factors are the most important and to what extent they determine economic growth. From a macroeconomic point of view, it should be stressed that different combinations of these factors influence the creation of economic resilience and thus countries can increase their long-term competitiveness and thus induce the most effective economic growth (Boikova et al., 2021).

Macroeconomic performance is influenced by a variety of interrelated factors that can significantly impact a country's economic growth. Traditionally, macroeconomic performance has been measured by indicators such as gross domestic product (GDP) per capita, employment rates and productivity growth. However, a more holistic view recognises that true macroeconomic performance should also reflect improvements in living standards, well-being and overall societal well-being. Key determinants include capital formation, government spending, foreign direct investment (FDI), inflation, and trade openness. Understanding these factors is crucial for policymakers aiming to enhance economic stability and growth (Makur, 2023). While these factors are generally recognized as vital for macroeconomic performance, it is important to note, that the interplay between them can vary significantly across different countries and contexts. For instance, while FDI is beneficial, its effectiveness can be diminished in environments with high political instability or poor governance (Chirwa & Odhiambo, 2016).

Digitalisation is changing the global economy and society at an unprecedented pace. Its impact on macroeconomic performance is wide-ranging, bringing both significant opportunities and new challenges. Digitalisation is the process of using digital technologies to transform business models, create new sources of revenue and generate opportunities for value creation. It is a broader shift towards a digital business or society that goes beyond simple digitisation (converting analogue information into digital form) and involves a fundamental change in processes and systems. It involves adapting systems to work with computers and the internet, as well as developing and transforming business processes using technologies such as the Internet of Things (IoT), big data, artificial intelligence (AI) and cloud computing (OECD 2019). Digitalization influences macroeconomic performance through enhanced productivity, innovation, and competitiveness, while also requiring robust digital infrastructure and skilled workforce to maximize its benefits (Bacho et al., 2019). Investment in digital infrastructure and ongoing skill development are essential to fully leverage the advantages of digitalization, fostering sustainable economic growth and improved quality of life for the population. These elements collectively contribute to a more resilient economy, capable of adapting to changes and challenges in the global market, ultimately benefiting society at large.

There are several studies that have analysed the impact of digitisation on the economic growth. Chenic et al. (2023) pointed out, that digitalization leads to increased labour productivity by integrating advanced technologies such as artificial intelligence and big data into production processes. A strong correlation was found between digitalization and value-added in economic activities, indicating that digital tools enhance the efficiency of resource utilization. According to Boikova et al. (2021) digitalization is a critical determinant of national competitiveness, influencing long-term economic growth rates and living standards. Countries, that invest in digital infrastructure tend to experience higher foreign direct investment and trade openness, further boosting economic performance. Another approach, represented by Asma et al. (2024) claims, that the integration of digital technologies can create new job opportunities while also necessitating a shift in workforce skills, impacting labour force participation rates positively. Enhanced communication and technology access can help integrate previously marginalized populations into the economy, fostering inclusive growth.

The interplay of these factors underscores the necessity for strategic policies that promote digitalization, ensuring equitable access and addressing potential disparities in the digital economy to foster inclusive growth and mitigate the risks associated with the digital divide, thereby enhancing overall economic security and stability (Khaustova, 2024).

While digitalization presents numerous benefits for macroeconomic performance, it also poses challenges, such as the risk of job displacement and the need for continuous skill development to keep pace with technological advancements. Balancing these factors is crucial for sustainable economic development. One of these is the so-called "productivity paradox". Despite rapid progress in digitisation, overall productivity growth has been slowing steadily in recent decades, contrary to expectations. This suggests that its benefits have not yet been fully realised, potentially as a result of the time it takes businesses to adopt complex software and make complementary investments (Chernenko et al., 2021). Another challenge is labour market disruption and skills shortages. Digital technologies can lead to job

losses, especially in routine tasks. While new opportunities are being created, there is a shift in labour demand towards new skill sets, which has a more negative impact on less educated workers and specific occupations. This requires investment in digital skills training and retraining of the workforce (Huseynli & Huseynli, 2022). Digitalisation can also lead to market concentration and inequality. Highly digital-intensive industries can be more dynamic and grow faster, but at the same time have seen a significant decline in business dynamism and an increase in market concentration. This can lead to excessive profits for technology companies and potentially widening income inequality (OECD, 2019).

Digitalization has become a critical factor for competitiveness recently. There is a rapid development of ICTs, which pressures enterprises to conduct business within the framework of the Fourth Industrial Revolution (Industry 4.0). With global markets and strong competition, some traditional manufacturing firms are implementing new maintenance innovations and policies, based on digitalization and a data-driven approach. This further indicates that the application of modern information–communication technologies (ICTs) by enterprises is an important factor in sustainable development. The enterprises must evaluate their business processes and identify which can be improved via ICT solutions such as information systems, cloud infrastructure, etc. (Boikova et al., 2021)

Sustainable development significantly influences a country's macroeconomic performance through various interconnected factors. These factors encompass innovation, human capital, foreign direct investment (FDI), and the overall business environment, which collectively contribute to economic growth while ensuring environmental and social sustainability. We can find several studies that deal with sustainability. Šofranková et al. (2021) highlight that innovation activity is essential for increasing productivity and competitiveness, leading to sustainable economic growth. According to Mumtaz et al. (2023), investment in human capital promotes a more competitive workforce, which is necessary to adapt to changing economic conditions and changes in markets caused by progress. The impact of FDI has been studied by Doloan (2024). According to him, FDI plays a key role in technology transfer and job creation, thereby contributing to higher economic performance.

Digital transformation is a process that requires certain skills regarding the use of new innovative digital technologies to increase economic performance and improve the quality of life. At the same time, quantifying the influence of digital technologies on economic development is one of the important concerns of scientific studies and analyses. Between digitization and economic growth, there is a direct relationship, as were analysed by Chenic et al. (2023).

To assess digital performance and sustainable competitiveness, we have selected the following indices: Digital Economy and Society Index (DESI), Network Readiness Index (NRI), and Global Sustainable Competititveness Index (GSCI). The choice of these three indices is based on their ability to comprehensively cover key dimensions: specific digital performance within the EU (DESI), digital readiness (NRI), and sustainable development in a global context (GSCI). Their combined use enables the identification of not only the technical readiness of countries for digital transformation but also its socioeconomic and environmental impacts, thus providing a foundation for a comprehensive and internationally comparable assessment.

The **Digital Economy and Society Index (DESI)** is a composite index created by the European Commission that monitors Europe's overall digital performance and tracks the progress of EU Member States in terms of digital competitiveness. It has been published annually through DESI reports since 2014. The main purpose of the DESI is to serve as a key tool for Member States to identify areas requiring priority investment and action in their digital transformation journeys. It provides country profiles and thematic analyses to inform policy decisions to accelerate digitalisation, increase resilience and reduce external dependencies within the EU (European Comission, 2025).

The **Network Readiness Index (NRI)** is a comprehensive indicator of countries' digital readiness, measuring their ability to leverage information and communication technologies (ICT) to support inclusive growth, innovation, and competitiveness. The index was first published in 2002 as part of the *Global Information Technology Report* under the auspices of the World Economic Forum. Since 2019, following a major methodological revision, the NRI has been managed by the independent research organization Portulans Institute, which focuses on advancing sustainable digital development. The primary objective of the index is to provide a comprehensive and internationally comparable **overview** of the state of digital readiness across countries in the context of sustainable development. The NRI also serves as an analytical tool for designing national digital strategies, identifying structural weaknesses, and monitoring progress in digital transformation and the knowledge-based economy (Dutta & Lanvin, 2025).

The **Global Sustainable Competitiveness Index (GSCI)**, developed by Solability, measures the competitiveness and sustainability of countries. First published in 2012, the GSCI defines sustainable competitiveness as the ability to generate and maintain inclusive wealth without reducing the future ability to maintain or increase current levels of wealth. The GSCI aims to provide a comprehensive alternative to traditional GDP measurements for assessing country performance, recognising that GDP alone is insufficient as it excludes key factors such as environment, health, education, security, governance and quality of life. It is used to assess country-specific risks and challenges for operators and investors, and to check countries' progress on their path to sustainability and competitiveness (Solability, 2025).

All three indexes (DESI, NRI, and GSCI) agree that gross domestic product (GDP) is not a sufficient indicator of national progress. They aim to provide a more comprehensive assessment that includes qualitative, non-economic, and long-term sustainable aspects of development. DESI focuses on the digital performance of European Union member states and provides detailed data on digital skills, digital infrastructure, the level of business digitalization, and the functioning of digital public services. NRI expands this perspective to a global context by assessing countries' readiness to leverage digital technologies in support of innovation, socio-economic development, and societal resilience to technological and social challenges. Compared to DESI, it has a global scope and a universally applicable methodology. GSCI differs in its emphasis on sustainable competitiveness. It evaluates countries based on environmental, economic, innovation-related, and institutional indicators. It applies the concept of a sustainable competitiveness pyramid, which posits that long-term economic growth and prosperity are conditioned by responsible use of natural capital, effective resource management, and social stability. The index provides a long-term and systemic perspective on countries' ability to remain competitive without compromising the prospects of future generations.

1.1 Digital Economy and Society Index

The Digital Economy and Society Index (DESI) serves as a tool of the European Commission (European Comission, 2025) for monitoring the digital performance of EU Member States and assessing their progress in the field of digital transformation. Since 2014, DESI has been published annually, and as of 2023, it has become an integral part of the broader State of the Digital Decade report, which reflects the EU's strategic objectives for 2030 outlined in the Digital Decade framework.

DESI enables the comparison of countries based on quantifiable indicators and provides individual country profiles that help identify areas requiring priority action. The annual DESI reports are complemented by thematic analyses of key areas of digital development at the EU level, thereby supporting the formulation of targeted digital policies.

From a methodological perspective, DESI has undergone several modifications to reflect the evolving nature of digital technologies as well as the need for alignment with the strategic goals of the EU's digital transformation. The current structure of the index is based on four main dimensions, in accordance with the EU's Digital Compass: Digital skills, Digital infrastructure, Digital transformation of businesses, and Digital public services. Each of these areas is assessed through multiple quantitative indicators, with an emphasis on measurable outcomes linked to progress toward the 2030 Digital Decade targets.

The relevance of DESI as both an analytical and policy-making instrument lies in its connection to the EU's financial mechanisms. The results of the index serve as a foundation for shaping national digital strategies and contribute to the strategic allocation of investments aimed at advancing the European digital transformation.

Overall, DESI functions not only as an evaluative framework but also as a strategic tool that facilitates informed decision-making, continuous progress monitoring, and the reduction of digital disparities within the European Union.

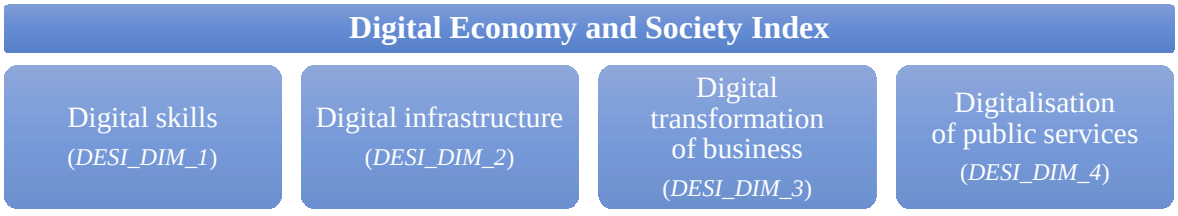

Figure 1. Structure of DESI
Source: own processing by European Commission (2025)

1.2 Network Readiness Index (NRI)

The Network Readiness Index (NRI) is used to measure countries' capacities to leverage opportunities offered by ICT and to assess their level of digital readiness. The NRI is one of the most significant indicators reflecting the digital development of nations, providing a much broader view of global digital preparedness (Bánhidi & Dobos, 2024). It is a composite index designed to capture the multifaceted impact of ICT on society and development.

Within the framework of the Network Readiness Index, countries are assessed in terms of infrastructure, innovation, and technology availability. It is a holistic framework that measures the impact of ICT across four key dimensions of society: technology, people, governance, and impact. Its aim is to integrate people with technology in a way that enhances the effectiveness of government strategies for the economy, society, and the environment, making it a reliable tool for measuring a country's e-readiness (Dutta & Lanvin, 2023).

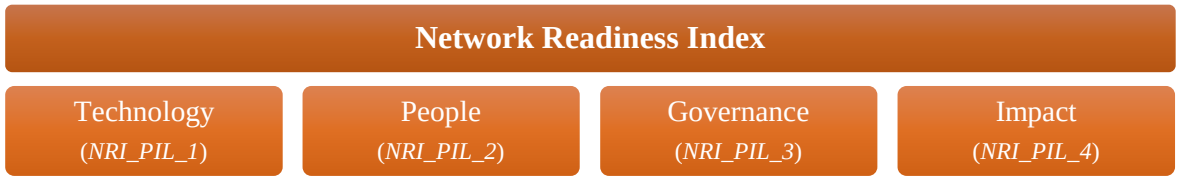

Figure 2. Structure of NRI
Source: own processing by Dutta & Lanvin (2025)

The NRI evaluates countries' digital maturity through four main pillars: technology, people, governance, and impact. These are further divided into twelve sub-pillars and approximately sixty indicators, combining both quantitative and qualitative data. The indicators cover areas such as the availability of digital infrastructure, the development of digital skills, the quality of regulatory frameworks, institutional effectiveness, and the broader socio-economic impact of digitalization.

1.3 Global Sustainable Competitiveness Index

The Global Sustainable Competitiveness Index (GSCI) measures the true competitiveness of nations. The GSCI is based on 120 purely quantitative indicators, derived from reliable sources (World Bank, UN agencies, the IMF), grouped in the 6 pillars of national competitiveness : Natural capital, Resource efficiency, Ssocial capital, Intellectual capital, Econoic Capital and Governace. The GSCI is the most comprehensive measurement of the competitiveness of nation-states and their future potential (Solability, 2025). GSCI is based on a pyramid system, i.e. each level of the index (pillar) affects the immediately following one and is necessary to support the higher level.

Figure 3. Structure of GSCI
Source: own processing by Solability (2025)

The Global Sustainable Competitiveness Index (GSCI) is constructed based on six main pillars that reflect the most important areas of sustainable development and long-term national competitiveness. These pillars encompass environmental, economic, social, innovation-related, and institutional dimensions. The index assesses the extent to which a country efficiently utilizes its natural resources, ensures social stability, promotes education and innovation, maintains a healthy business environment, and demonstrates effective governance of public policy. Each pillar is based on a set of quantitative indicators, and the index as a whole includes more than 180 indicators drawn from internationally recognized databases. This approach enables the comparison of countries in terms of their long-term ability to generate sustainable wealth and prosperity.

2. Methods

The main objective of this study was to investigate the interrelationships between digital performance, network readiness, and sustainable competitiveness across the EU-26 member states over the period 2017– 2022. To achieve this, the analysis was based on secondary data derived from three internationally recognized indices: the Digital Economy and Society Index (DESI), the Network Readiness Index (NRI), and the Global Sustainable Competitiveness Index (GSCI). The data sources included annual reports published by the European Commission (DESI), the Portulans Institute (NRI), and SolAbility (GSCI). Due to the incompleteness of specific datasets, two countries were excluded from the analysis (Malta and the United Kingdom). In addition, the Economic Capital pillar (GSCI_PIL_5) was omitted from the GSCI structure as it lacked complete time series data across the full sample of countries.

The main objective was fulfilled through two partial objectives, which were defined in a logical sequence as follows:

- *Partial Objective 1* → To compare the EU-26 countries based on the average scores of selected global indices (DESI, NRI, and GSCI) over the period 2017–2022;
- *Partial Objective 2* → To identify the existence of mutual relationships and interdependencies between the overall scores and the dimensions of the selected global indices for the EU-26 countries using correlation analysis.

For Partial Objective 2, we formulated the following hypotheses, which were tested using appropriate statistical tools:

- H1: *We assume the existence of statistically significant relationships between the overall scores and the dimension/pillars scores of the DESI and NRI indices for the EU-26 countries during the period 2017–2022;*
- H2: *There is a statistically significant impact of the dimension scores of the DESI and NRI indices on the overall GSCI score and its dimension scores for the EU-26 countries over the period 2017– 2022.*

To verify the research hypotheses, the non-parametric Kendall's Tau correlation test was selected. The choice of this coefficient was based on the results of normality tests (Kolmogorov-Smirnov test, Lilliefors test, and Shapiro-Wilk test), which indicated that the assumption of normal distribution was not met for some variables in the secondary dataset of the analyzed indices. The interpretation of the correlation coefficient is often problematic, as there are no universally accepted threshold values. Based on the absolute value of the correlation coefficient, Chajdiak (2013) defined the following three levels of dependency strength: low dependency (0.1–0.39), moderate dependency (0.4–0.79), and strong dependency (0.8–1). This scale served as the basis for evaluating the intensity of the correlation relationships.

3. Results

In the following section of our contribution, we focus on the analysis of the results related to the assessment of digital performance and sustainable competitiveness of the EU-26 countries for the period 2017 to 2022, structured according to the predefined partial objectives.

3.1 Development of the average score of the analyzed indices in the EU-26 countries

As part of the analysis of the digital and sustainable performance of the European Union member states, the average values of three complementary indices were compared: the Digital Economy and Society Index (avg_DESI), the Network Readiness Index (avg_NRI), and the Global Sustainable Competitiveness Index (avg_GSCI). These indices provide an integrated perspective on the level of digital readiness, network infrastructure, and long-term competitiveness based on the principles of sustainable development.

The Digital Economy and Society Index (DESI) assesses the progress of countries in terms of digital transformation and digital capabilities, including digital public services, connectivity, human capital, and the integration of digital technologies into business. The average DESI score for 26 EU member states reached 42.23 points, with the highest scores recorded in Northern European countries as Finland (57.26), Denmark (56.30), and Sweden (54.65). Conversely, the lowest values were observed in Romania (24.21), Greece (28.40), and Bulgaria (29.65), indicating persistent digital disparities across regions.

The Network Readiness Index (NRI) measures the ability of countries to leverage information and communication technologies for economic and social development. It considers factors such as access

to technology, regulatory environment, quality of infrastructure, population skills, and socio-economic impact. The average NRI score for the analyzed countries reached 66.32 points, with top positions again held by Sweden (79.43), the Netherlands (79.00), and Finland (78.47). On the other hand, below-average scores were recorded in Romania (54.37), Bulgaria (54.47), and Greece (55.10).

The following graphic shows a comparison of the digital performance of EU-26 countries using the DESI and NRI indices.

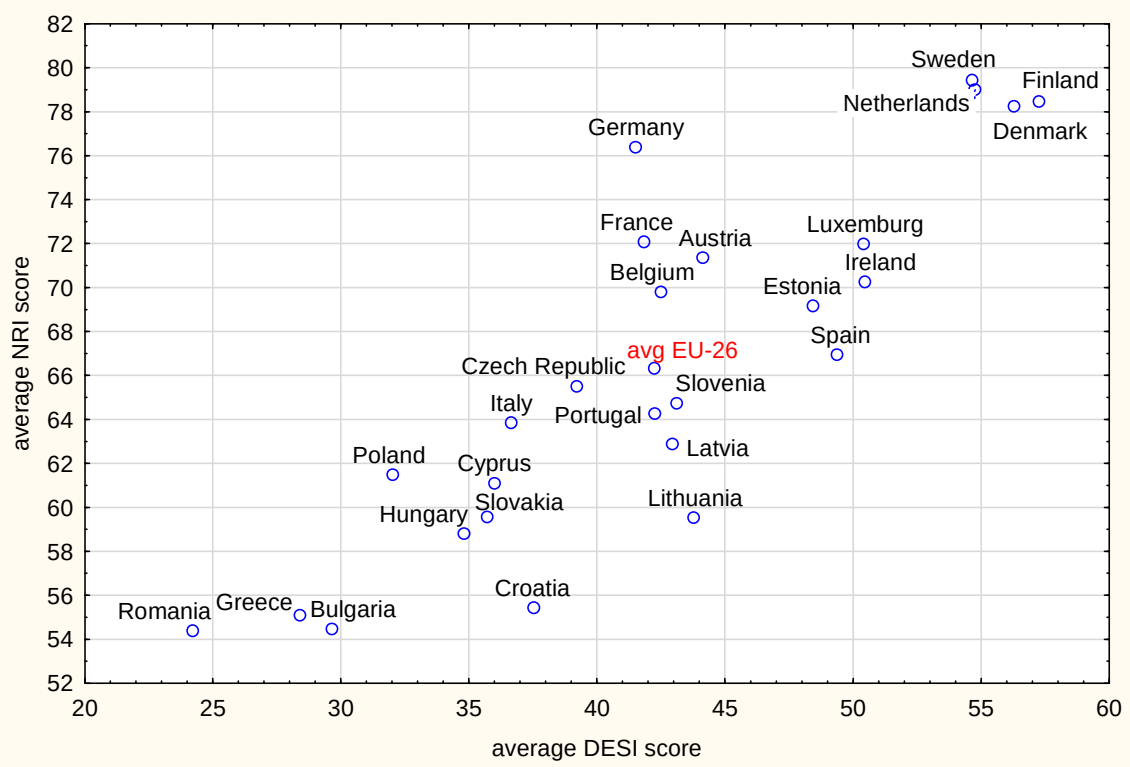

Figure 4. Relationship between avg DESI score and avg NRI score in EU-26 (2017-2022)
Source: own processing

The final index analyzed is the Global Sustainable Competitiveness Index (GSCI), which assesses a country's long-term potential in terms of environmental sustainability, economic stability, innovation, and social cohesion. The average value for the EU-26 countries reached 53.25 points, with the highest scores once again recorded in the Nordic countries such as Sweden (61.07), Finland (59.31), and Denmark (58.44). The countries with the lowest performance included Cyprus (45.57), Greece (48.40), and Bulgaria (48.82).

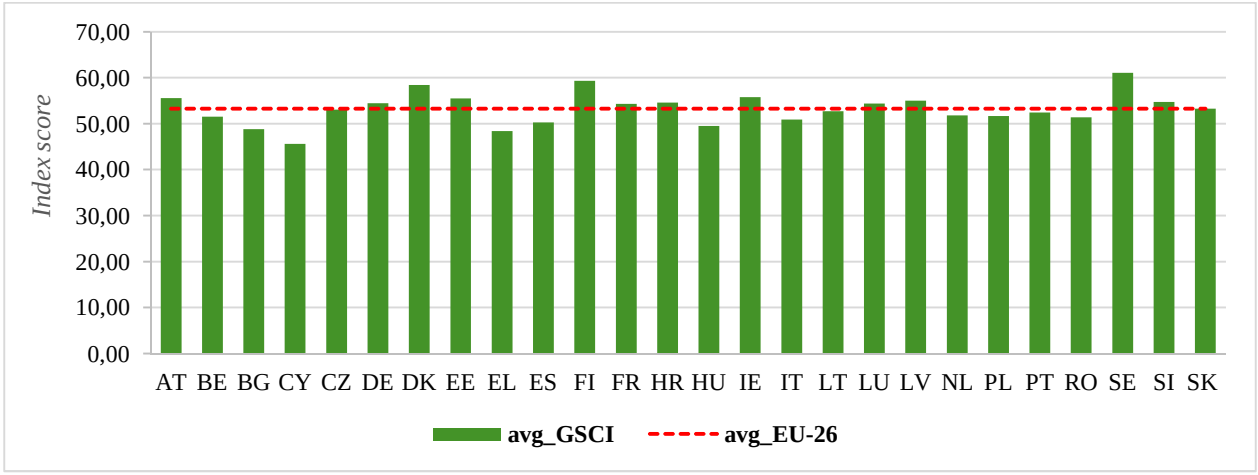

Figure 5. Comparison of the average GSCI index scores of the EU-26 countries (2017-2022)
Source: own processing

The results indicate that Northern and Western European countries achieve above-average performance across all three indicators, reflecting their high level of digital maturity, innovation potential, and commitment to sustainable development. In contrast, Southeastern European countries face systemic challenges related to digital infrastructure, skills availability, and the implementation of sustainable policies. This disparity highlights the need for targeted cohesion policy at the EU level aimed at strengthening the digital and environmental resilience of the least performing regions.

3.2 Results of the correlation analysis between the selected indices of the EU-26 countries

In this part of the paper, we focused on the results of the correlation analysis, which is directly linked to the second partial objective and the associated hypotheses (H1 and H2) defined within that objective.

The results of the correlation analysis using the Kendall coefficient, aimed at examining the relationships between the overall scores and the individual dimensions/pillars of the DESI and NRI indices, are presented in Table 1 and indicate several statistically significant moderate and weaker associations ($p < 0.05$).

Table 1. Results of the correlation analysis between the overall scores and the dimensions of the DESI and NRI

Variable	Kendall Tau Correlations MD pairwise deleted			Marked correlations are significant at p <0.05	
	NRI	*NRI_PIL_1* *Technology*	*NRI_PIL_2* *People*	*NRI_PIL_3* *Governance*	*NRI_PIL_4* *Impact*
DESI	0.3658	0.2514	0.2237	0.5815	0.4100
DESI_DIM_1 *Digital skills*	0.5238	0.4106	0.3719	0.6307	0.5465
DESI_DIM_2 *Digital infrastructure*	0.0701	-0.0032	-0.0350	0.2774	0.1282
DESI_DIM_3 *Digital transformation of business*	0.3614	0.2554	0.2234	0.4766	0.4469
DESI_DIM_4 *Digitalization of public services*	0.3617	0.2450	0.2412	0.5843	0.3785
Note: *0.1 - 0.39 → low dependence*		*0.4 - 0.79 → medium dependence*		*0.80 - 1.00 → higher dependence*	

Source: own processing

In the first part of the correlation analysis, the internal relationships between the overall DESI score and its individual dimensions were examined. The results reveal that the strongest association (τ = 0.8161) was observed between the overall DESI score and DESI_DIM_4 (*Digitalization of public services*), underlining its critical role in shaping the digital performance of countries. A moderate level of correlation was identified for DESI_DIM_3 (*Digital transformation of businesses*) with value of τ = 0.6905 and DESI_DIM_1 (*Digital skills*) with value od τ = 0.6292. The weakest moderate positive correlation (τ = 0,5769) was found between the overall DESI score and DESI_DIM_2 (*Digital infrastructure*), which may suggest that during the 2017–2022 period, infrastructure alone ceased to be a key differentiating factor among EU member states.

In the case of the NRI index, the strongest moderately positive association (τ = 0.7771) between the overall NRI score and the individual pillars was observed for NRI_PIL_1 (*Technology*), followed by NRI_PIL_4 (*Impact)* with τ = 0.7646, and NRI_PIL_2 (*People*) with τ = 0.7515. The weakest correlation, though still moderately positive, was recorded for NRI_PIL_3 (*Governance*), with τ = 0.6686.

In the third step, relationships between the overall DESI and NRI scores, as well as between their dimensions and pillars, were analyzed. A positive correlation was identified between the overall score of the DESI index and the overall score of the NRI index, with a Kendall's Tau value of 0.3658, which represents a low dependence according to the interpretation scale. This correlation is statistically significant ($p < 0.05$), indicating a demonstrable positive relationship between the level of digital performance measured by DESI and the overall digital readiness as assessed by NRI across the EU-26 countries. In practical terms, this suggests that countries with higher DESI scores tend to also achieve higher values in the NRI, although the relationship is not particularly strong, likely due to methodological and conceptual differences between the two indices.

From a structural perspective, the strongest pozitive correlation was observed between DESI_DIM_1 (*Digital skills*) and NRI_PIL_3 (*Governance*) (τ = 0.6307), confirming that the population's digital skills significantly contribute to the quality of digital governance. Moderately strong associations were also identified between NRI_PIL_3 (*Governance*) and DESI_DIM_4 (*Digitalization of public services*) (τ = 0.5843), as well as with DESI_DIM_3 (*Digital transformation of business*), which showed a correlation of τ = 0.4766. Additionally, two other moderately positive relationships were observed between DESI_DIM_1 (*Digital skills*) and NRI_PIL_4 (*Impact*) with τ = 0.5465, and NRI_PIL_1 (*Technology*), with a correlation coefficient of τ = 0.4106. On the contrary, correlations for DESI_DIM_2 (*Digital Infrastructure*) and the total NRI score and two NRI pillars, namely for NRI_PIL1 (*Technology*) and NRI_PIL_2 (*People*), were not confirmed.

In the next phase of the analysis, we focused on examining the relationships between digital performance (as measured by the DESI and NRI indices) and sustainable competitiveness (as captured by the GSCI index) of the EU-26 countries, considering not only the overall scores but also the individual dimensions and pillars of these composite indicators. Due to the incompleteness of available secondary data, the *Economic Capital pillar* (GSCI_PIL_5) was excluded from the GSCI index analysis.

Table 2. Results of the correlation analysis between GSCI, DESI, and NRI indices

Variable	Kendall Tau Correlations MD pairwise deleted *GSCI*	Marked correlations are significant at p <0.05 *GSCI_PIL_1* *Natural capital*	*GSCI_PIL_2* *Resource Efficiency*	*GSCI_PIL_3* *Social capital*	*GSCI_PIL_4* *Itellectual Capital*	*GSCI_PIL_6* *Governance*
DESI	0.4439	0.1065	0.1921	0.5350	0.2603	0.2031
DESI_DIM_1	0.4838	0.1228	0.2139	0.3899	0.3459	0.1752

Note: 0.2 - 0.39 → low dependence | *0.4 - 0.79 → medium dependence* | *0.80 - 1.00 → higher dependence*

Source: own processing

In the first part of this analysis, the relationship between the overall GSCI score (Global Sustainable Competitiveness Index) and two key digital indices – DESI and NRI – was examined. The results revealed a moderate positive correlation between GSCI and DESI (τ = 0.4439), and a weaker but statistically significant correlation between GSCI and NRI (τ = 0.3635). These findings suggest that countries with higher levels of digital performance, as measured by DESI, as well as greater digital readiness according to NRI, also tend to achieve better outcomes in terms of sustainable competitiveness.

From the perspective of the GSCI components, the strongest correlation was identified with DESI_DIM_1 (*Digital skills*) (τ = 0.4838), indicating a strong relationship between digital skills and the level of sustainable performance and competitiveness among European countries. In the case of the NRI, the strongest correlation was observed with NRI_PIL_3 (*Intellectual capital*) (τ = 0.4773), confirming the importance of the link between digital readiness and a country's innovation potential.

Relationships between DESI dimensions and GSCI pillars

An analysis of the relationships between the DESI index dimensions and the NRI pillars reveals that only three cases demonstrated a moderately strong positive correlation. Specifically, these include the relationships between GSCI_PIL_3 (*Social capital*) and DESI_DIM_3 (*Digital transformation of business*), DESI_DIM_4 (*Digitalization of public services*), and DESI_DIM_2 (*Digital infrastructure*). The remaining Kendall's tau values fell within the range of 0.1–0.39, indicating weak associations.

In three specific cases, no statistically significant correlation was confirmed: namely, between GSCI_PIL_1 (*Natural capital*) and both DESI_DIM_2 (*Digital infrastructure*) and DESI_DIM_3 (*Digital transformation of business*), as well as between GSCI_PIL_4 (*Intellectual capital*) and DESI_DIM_2 (*Digital infrastructure*).

Relationships between NRI pillars and GSCI pillars

In the analysis of individual pillars of the GSCI and NRI indices, a moderate correlation was confirmed between GSCI_PIL_4 (*Itellectual capital*) and all pillars of the NRI. Two pillars, GSCI_PIL_2 (*Resource Efficiency*) and GSCI_PIL_3 (*Social capital*), exhibited weak correlations, while GSCI_PIL_6 (*Governance*) showed a Kendall's tau coefficient above 0.17 in its relationships with NRI_PIL_3 (*Governance*) and NRI_PIL_4 (*Impact*). It is also worth noting that no statistically significant relationship was identified between GSCI_PIL_1 (Natural capital) and the overall NRI score, nor with any of its individual pillars. The highest observed Kendall's tau value was 0.5132, reflecting the relationship between GSCI_PIL_4 (*Itellectual capital*) and NRI_PIL_4 (*Impac*t).

These findings highlight that sustainable competitiveness is not solely driven by the existence of digital infrastructure, but more importantly by investments in human capital, innovation, digital public services, and the quality of governance. A key insight is that the DESI index demonstrates more consistent links with the GSCI compared to the NRI, suggesting higher sensitivity to current digital performance. In contrast, the NRI better reflects the strategic foundations of digital readiness, although some of its components such as technological infrastructure did not prove to be critical drivers of sustainable development.

The results indicate that the most significant relationships between GSCI and the digital indices are concentrated in the areas of social and intellectual capital, with digital skills, digital services, and the quality of digital governance emerging as key factors of sustainable competitiveness. The DESI index shows more consistent associations with GSCI than the NRI, but both indices confirm that advanced digital infrastructure alone is not sufficient and investments in people, innovation, and the public sector are essential.

4. Discussion

The results of the analysis of average scores and interrelationships between the DESI, NRI, and GSCI indices for the EU-26 countries over the 2017–2022 period provided important insights into the links between digital performance, digital readiness, and sustainable competitiveness. The findings clearly highlight regional disparities in digital and sustainable performance, with Northern and Western European countries consistently achieving above-average results, while Southeastern Europe continues to face persistent challenges.

The comparative analysis revealed a statistically significant yet moderate positive correlation between DESI and NRI scores. This confirms that digital performance and digital readiness are related but conceptually distinct dimensions. While the DESI focuses more on the practical implementation of digital solutions, the NRI reflects a broader capacity of countries to adapt to digital transformation, including institutional and societal factors.

The detailed correlation analysis showed that the key determinants of digital performance are primarily digital skills, the digitalization of public services, and the digital transformation of business. Within the NRI, the most influential pillars were Governance and Impact, highlighting the importance of effective public administration and a country's ability to translate digital investments into tangible social and economic benefits.

Regarding the relationship with sustainable competitiveness (as measured by the GSCI), the results indicate that digitally advanced countries also tend to achieve higher levels of social and intellectual capital, confirming the relevance of soft factors such as trust, education, innovation, and quality of life. Conversely, technological infrastructure and access to technology alone showed limited or no significant connections to long-term competitiveness, emphasizing the need for a holistic approach to digital development.

In conclusion, the results support the validity of Hypothesis H1, confirming the existence of statistically significant relationships between the overall scores and the dimensions of the DESI and NRI indices. Hypothesis H2 was also confirmed, as a statistically significant relationship was found between digital indices (especially DESI) and the overall sustainable competitiveness score (GSCI).

Conclusion

The results of the analysis of digital performance and sustainable competitiveness across the EU-26 countries for the period 2017–2022 revealed significant regional disparities within the European Union. Northern and Western European countries consistently ranked at the top across all analyzed indices (DESI, NRI, and GSCI), while Southeastern European countries lagged behind, particularly in areas such as digital infrastructure, digital skills, and the quality of public governance.

The comparative assessment of the DESI and NRI indices revealed a high level of consistency in identifying digital frontrunners and laggards. However, key methodological differences exist between the two: DESI is primarily oriented toward measuring the practical outcomes of EU digital policies andthe implementation of digital solutions, thereby reflecting current performance in the digital economy and governance. In contrast, the NRI adopts a more forward-looking perspective, emphasizing institutional preparedness, regulatory frameworks, and the long-term impacts of digitalization. This distinction suggests that DESI is particularly suitable for evaluating the effectiveness of national and EU digital policies, while NRI provides a broader framework for understanding a country's potential to leverage digital technologies as a driver of economic and social transformation.

Correlation analysis confirmed that digital skills, quality of digital governance, digitalization of public services, and innovation capacity are critical factors for both high digital performance and sustainable competitiveness. Conversely, mere technological availability or infrastructure, without strategic implementation, does not significantly influence long-term national performance.

Based on the tested hypotheses, we conclude that there are statistically significant and substantively meaningful relationships between the dimensions of digital indices (especially DESI) and performance insustainable competitiveness (GSCI). These findings affirm the role of digitalization as a key driver not only of economic growth but also of socially and environmentally sustainable development.

We therefore recommend the combined use of the DESI and NRI indices in analytical practice, as their integration enables a more comprehensive assessment of both the current state of digitalization and its long-term sustainability and systemic resilience. These insights can serve as valuable input for policymakers at both national and EU levels when designing targeted support for less advanced regions and shaping the long-term digital strategy of the European Union.

Abstract

Research background: The labor market faces new challenges, including slowing economic growth, the energy crisis, digitalization, migration, and the introduction of additional customs tariffs. These factors affect both employers and employees, making flexibility an essential aspect of the labor market. In recent years, there has been a significant rise in non-standard forms of employment, one of which is agency work.
Purpose of the article: The article examines the labor market and the factors prompting employers to adopt non-standard employment models, and analyzes the motivations influencing individuals to choose agency work. It also investigates the role of agency work in employing Ukrainian citizens seeking refuge and job opportunities in Slovakia due to the ongoing conflict.
Methods: The research is based on a questionnaire survey conducted with agency workers. The survey data were evaluated using methods of descriptive and inferential statistics.
Findings & Value added: Survey results indicate a strong demand for agency work in sectors such as the automotive industry, manufacturing, logistics, and retail work, and 62.7% wished to continue in such positions. Based on a questionnaire survey conducted among 376 agency workers in Slovakia, we can conclude that key motivations for choosing this type of employment include easy access to jobs, weekly wage payments, and the opportunity to earn additional income. Nearly 80% of respondents expressed satisfaction with agency. This article enhances the understanding of the flexibility of agency work, which will be particularly important in the face of future economic shocks, such as the introduction of tariffs by the United States, and provides valuable insights for employers and policymakers.

Keywords: Agency Employment, Flexibility, Labor Market, Slovakia

JEL classification: J20, J61

1. Introduction

In recent decades, the global labor market has undergone a series of transformative changes resulting from economic, technological, and geopolitical disruptions. Among the most prominent challenges are slowing economic growth, the global energy crisis, rising digitalization, the spread of artificial intelligence (AI), and increasing migratory movements due to armed conflicts. These dynamics have reshaped employment systems, prompting both employers and policymakers to reconsider how labor is structured, regulated, and mobilized (Chen et al., 2024; Palmer, 2024; Wiese et al., 2025).

One of the clearest indicators of this transformation is the rising prevalence of non-standard employment relationships (NSE). These forms of employment, which include temporary contracts, part time positions, platform based gig work, and agency mediated jobs, have increasingly replaced the previously dominant standard employment relationship (SER), which was defined by full time, open ended contracts with a single employer (ILO, 2023). NSEs offer flexibility in terms of time, location, and job duration, which aligns with the needs of an increasingly volatile economic environment and a diversifying workforce (Kalleberg, 2018; Klindzic & Marić, 2019).

For employers, NSEs serve as a strategic mechanism to reduce labor costs, manage workforce fluctuations, and avoid the regulatory constraints associated with permanent hiring. For workers, they may provide faster job access, short-term income, and flexibility in balancing work with personal

[*] Corresponding author: dstellarova@ukf.sk

obligations. However, these arrangements are often associated with job insecurity, reduced access to social protections, lower wages, and limited career advancement opportunities (Laß & Wooden, 2020; van Riemsdijk, 2024).

A particularly relevant form of NSE is temporary agency work, in which the worker is formally employed by a staffing agency but performs duties under the supervision of a user company. This triangular employment relationship introduces complex legal and institutional ambiguities regarding responsibility, protections, and rights (Hünefeld et al., 2020; Winkler & Mahmood, 2015). While this system allows employers to adjust their labor force efficiently, it also exposes workers to potential precarity and limited integration into the host company.

In countries facing labor shortages, particularly within the manufacturing, logistics, food processing, and retail sectors, agency employment has emerged as a critical mechanism for addressing workforce demands. In Slovakia, this trend has become especially pronounced due to the impact of the COVID-19 pandemic and the ongoing war in Ukraine, which have significantly altered labor supply and demand structures (Valaskova et al., 2024; Svabova et al., 2021). The war has displaced millions of Ukrainians, a large proportion of whom have sought refuge and employment in neighboring countries, including Slovakia.

Since 2022, Slovakia has granted temporary protection status to Ukrainian citizens, simplifying their access to the labor market and providing a fast-track employment route without the need for asylum or work permits (ÚPSVAR, 2023; Ministry of Interior SR, 2024). By early 2024, more than 138,000 individuals had registered for temporary protection in Slovakia, with women making up over 60% of this population. Although 58 percent of respondents on Profesia.sk reported holding a master's degree, the majority of Ukrainian refugees are employed in low-skilled positions due to language barriers, the non-recognition of foreign qualifications, and short-term integration expectations (SBA).

This mismatch between skills and job placement has made temporary agency work a dominant entry point into the Slovak labor market for refugees. While such jobs offer immediate income, they often lack stability and upward mobility. According to van Riemsdijk (2024), even highly skilled refugees frequently find themselves in precarious roles due to systemic governance gaps, resulting in limited long-term integration and diminished career potential. Furthermore, the overrepresentation of refugees in flexible and temporary roles reinforces existing labor market segmentation and inequality, particularly in times of crisis.

Agency work thus represents both a solution and a challenge: it provides a short-term answer to labor shortages and refugee integration, but it also introduces risks related to precariousness and unequal treatment. As Palmer (2024) points out, even high-wage migrant workers may encounter institutional limitations in claiming their rights, particularly in systems where labor protections are fragmented or dependent on employer mediation. For lower-wage migrants and refugees, this risk is further amplified by dependence on agencies that may also control access to housing, transportation, and other social services (McGauran et al., 2016).

The application of digital technologies and AI is also reshaping labor market dynamics. While automation and AI can enhance productivity, they often displace low-skilled workers and shift labor income towards capital income, exacerbating income inequality (Chen et al., 2024). In sectors such as manufacturing and services, AI implementation may improve overall efficiency but also erode the relative bargaining power of labor, especially in positions prone to automation. In this context, flexible forms of employment are not just an economic strategy but a structural outcome of broader technological transformation (Wiese et al., 2025).

2. Methods

In recent years, we have observed a rise in non-standard forms of employment on the Slovak labor market. One such form is agency employment. The aim of this article is to examine the factors that motivate individuals to work through employment agencies and to identify the sectors in which agency workers are employed.

In the first phase, a literature review of domestic and international authors was conducted based on the analysis of secondary sources. Scientific methods such as summarization, synthesis of knowledge, analogy, and deduction were used during this phase. The second phase focused on the analysis of primary data obtained from agency workers through a questionnaire survey.

To analyse the labor market and agency employment as one of the flexible forms of work, we formulated the following research questions:

- RQ1: What is the demographic structure of the respondents?
- RQ2: How long did the respondents search for work, and how difficult was their job search?
- RQ3: What are the reasons respondents chose to work through a staffing agency, what type of employment contract do they have, and what position do they hold?
- RQ4: How long has their employment lasted, how satisfied are they with agency work, and are they interested in continuing to utilize this form of work? Does the respondents' nationality influence their satisfaction with agency work?
- RQ5: What benefits do staffing agencies offer to employees?

To achieve the set objectives, we created an anonymous questionnaire. The survey was conducted among agency workers from March 4th, 2024, to May 31st, 2024. The questionnaire contained 14 questions, of which 11 were closed-ended and 3 were open-ended.

In the first part of our questionnaire, we focused on the demographics of the respondents. We collected information on gender, age, nationality, and current place of residence.

In the second part, we investigated the duration for which the respondent was unemployed before starting their current employment and how they rated the difficulty of finding their current job. We also inquired about the nature of the employment relationship the respondent entered into with the staffing agency, including its duration and the position they currently hold.

The third part of the questionnaire was aimed at identifying the factors that motivate respondents to become employed through a staffing agency. Simultaneously, we sought to determine whether they are currently satisfied with working through a staffing agency and whether they plan to continue in this type of employment in the future. At the end of the questionnaire, we examined the benefits provided by staffing agencies.

The questionnaire served as the main source of primary data for our study. Prior to data collection, we conducted a pilot test with a sample of 12 respondents. Based on their feedback, we made necessary adjustments to ensure the clarity and specificity of the questions and answers. The research sample was constituted through a convenience sampling technique. The questionnaire was administered in two formats, online and paper based, with staffing agencies assisting in the distribution among their temporarily assigned employees. Given the high number of Ukrainian citizens seeking temporary refuge in Slovakia, we also distributed the questionnaire in Ukrainian.

We carried out the analysis of the questionnaire survey using the methods of descriptive statistics and reliability analysis. Further, we used dependency analysis using Contingency tables. The Cramer's V was used to measure the strength of the relations. We analyzed the answers obtained using *IBM SPSS software*.

3. Results

In this section, we present the results of the questionnaire survey. The total number of respondents who participated in our survey reached 376. We began our data analysis with a reliability analysis. The Cronbach's Alpha coefficient was 0.67, indicating an acceptable level of reliability.

The first part of the questionnaire was designed to address RQ1. Interestingly, 50% of the respondents were women and 50% were men. The majority of respondents, 77.4%, were of Slovak nationality, followed by citizens of Ukraine (18.9%), the Czech Republic (3.8%), and Hungary (0.5%). Nearly 76% of the respondents were younger than 45 years. The least represented age group was those over 55 years, comprising only 6.38%.

In terms of educational background, the most represented respondents had secondary education with a school-leaving certificate (40%) or vocational training (26%). The smallest representation was among respondents with a bachelor's degree (9%) and those with a master's degree (7%). Highly educated individuals often prefer to seek employment outside of staffing agencies, as these agencies primarily fill positions that do not require a high level of qualification.

Responses to the question, "How long were you unemployed before starting your current employment?" can be seen in Figure 1.

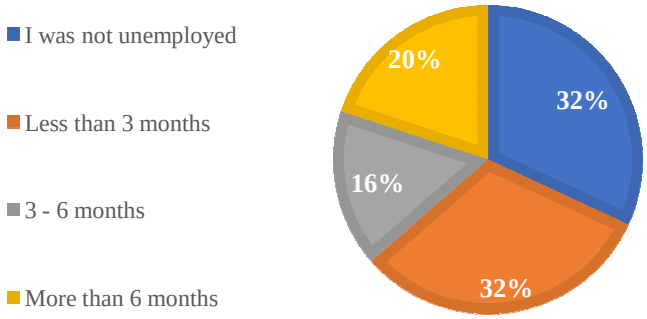

Figure 1. Duration of Unemployment Before Starting Current Employment
Source: own processing (2025)

We can conclude that up to 80% of respondents were unemployed for less than six months, indicating that agency work is not primarily sought by the long-term unemployed.

In the next part of the questionnaire, respondents evaluated the difficulty of finding employment. Only 22.87% of respondents found job searching to be challenging, predominantly those who had been unemployed for more than six months.

To determine the main reasons why people, choose to work through staffing agencies, we asked respondents about their motivations for selecting this type of employment relationship. Respondents could choose from the provided answers or write in other reasons. For 41% of respondents, the most important factor was the ease of obtaining work. An additional 17% indicated that the main reason was the opportunity to earn extra income, while 9% needed temporary work. The benefits provided by the agency, which often surpass those offered directly by employers, also played a significant role in their decision-making; this reason was mentioned by 9% of respondents (Table 1).

Table 1. Factors Influencing Motivation to Work Through a Staffing Agency

Reason for Choosing the Job via an Employment Agency	Number of Respondents	Percentage (%)
It was the easiest way to get a job	154	41%
In this company, it is only possible to work through an agency	6	2%
It is a stepping stone for me	28	7%
The employment agency can offer me another job, if I'm not satisfied	26	7%
The employment agency offers benefits that the employer cannot provide (accommodation/ wage advances/ transport to work, etc.)	33	9%
It helps with professional development	4	1%
I needed an additional income	63	17%
I needed a temporary job	32	9%
I needed to gain work experience	26	7%
Good experiences with a specific employment agency	4	1%

Source: author (2025)

Another question investigated the type of employment relationship respondents had established with the staffing agency and the positions they hold. The findings revealed that 70% of respondents had a full-time employment contract with the staffing agency, while 10% had a part-time contract. Additionally, 10% of respondents worked under a work performance agreement, and 9% had a student work agreement. Only one respondent indicated having a work activity agreement with the staffing agency.

Regarding the job positions held by respondents, the most represented group was that of production operators/production workers, comprising 74% of the total respondents. Conversely, the least represented positions were in the IT sector. Based on the results, we can conclude that staffing agencies primarily fill low-specialization positions with minimal educational requirements.

The results also show that 46% of respondents have been in their current employment for more than six months. See Figure 2 for more details.

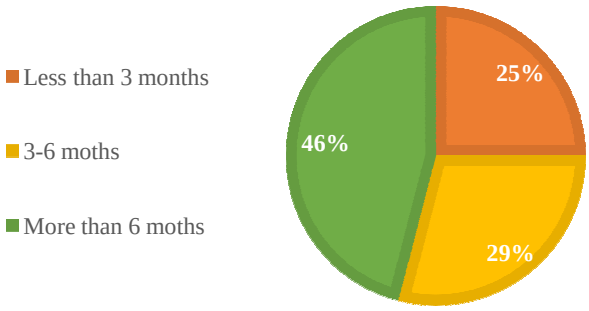

Figure 2. Duration of Employment Relationship
Source: own processing (2025)

In the next section of the questionnaire, we assessed respondents' satisfaction with agency work and their interest in continuing to work through staffing agencies. Responses were measured on a five-point Likert scale, ranging from "strongly agree" to "strongly disagree." The results can be seen in Table 2.

Table 2. Satisfaction with Agency Work

Response Category	Currently Satisfied (Number)	Currently Satisfied (%)	Future Interest (Number)	Future Interest (%)
Strongly agree	143	38%	122	32%
Agree	152	40%	114	30%
Neutral opinion	62	16%	96	26%
Disagree	17	5%	29	8%
Strongly disagree	2	1%	15	4%

Source: author (2025)

In terms of current satisfaction with agency work, 78% of respondents perceive their work through a staffing agency positively.

Finally, we were interested in whether nationality affects current satisfaction with the working environment provided by the staffing agency. To this end, we divided respondents into Slovak and foreign employees. To examine the dependency, we used Cramér's V, which equaled 0.082 with a p-value of 0.465. We can conclude that current satisfaction is not influenced by nationality. Our conclusion was assessed at a significance level of 0.05.

Regarding the interest in continuing agency work in the future, the results indicate a slight decrease in positive attitudes. 62% of respondents expressed interest in continuing to utilize the services of a staffing agency, while 12% disagreed with the idea of continuing agency work in the future.

RQ5 focuses on examining the benefits provided by staffing agencies. The results indicate (Table 3) that the most frequently mentioned benefit by respondents was the option for advance wage payments or weekly wage payments.

Table 3. Benefits Offered by Staffing Agencies

Benefit	Frequency
Professional counseling (preparation for a job interview, legal advice, assistance with permits)	126
Accommodation	82
Option to take salary advances / weekly salary payments	182
Transportation to work	143

Source: author (2025)

4. Discussion

Based on the analysis of empirical data, we were able to answer all the research questions. The majority of respondents in our study were of Slovak nationality (77.39%), while a significant portion consisted of Ukrainian citizens (18.88%), reflecting current migration trends. The primary reason respondents chose to work through a temporary employment agency was the relative ease of obtaining a job. For migrants, this form of employment facilitates entry into the labor market, a finding that is supported by international studies. For instance, Lamb, Banerjee, and Verma (2021) report that non-standard jobs often serve as an entry point to the Canadian labor market for many new immigrants.

In the case of Croatia, Strmota and Ivanda (2021) argue that the expansion of atypical forms of employment is more a consequence of the lack of full-time job opportunities than a reflection of employer-driven labor market flexibility.

Nearly 80% of our respondents expressed satisfaction with their agency employment, indicating a generally positive perception of this type of work. We found that nationality is not a key factor influencing satisfaction with agency work. However, interest in continuing this form of employment in the future was slightly lower, suggesting the need for further improvements in working conditions and the long-term prospects of agency-based employment.

The findings of this study highlight the significant role of temporary employment agencies in increasing labor market flexibility in Slovakia, particularly in the employment of temporary and low-skilled workers. These results are consistent with the findings of Zhang, Nardon, and Sears (2022), who point out the specific challenges and risks associated with non-standard employment among migrants, while also emphasizing its importance as a mechanism for labor market integration.

Conclusion

Labor market flexibility has become a necessity in today's dynamic environment. The COVID-19 pandemic, the energy crisis, and rising tariffs have demonstrated that the ability to adapt quickly to changing conditions is essential for the survival and success of businesses. In this context, temporary agency work represents a key instrument that enables companies to respond effectively while offering workers the opportunity to gain experience and access new employment opportunities during times of uncertainty.

The findings of the study provide valuable insights into the motivations and experiences of employees working through employment agencies in Slovakia. The results indicate that staffing agencies play a significant role in enhancing labor market flexibility, particularly by facilitating employment for temporary and lower-skilled workers. Temporary agency work helps these individuals acquire practical experience and access job opportunities during economically unstable periods.

Furthermore, the findings underscore the pivotal role of staffing agencies in facilitating the integration of foreign workers, particularly Ukrainian nationals, into the Slovak labor market, in accordance with contemporary migration patterns. The study also points to the potential for strengthening and expanding the benefits of agency employment, which could, in the long term, enhance its attractiveness. These findings may also serve as a useful resource for policymakers in the field of employment, as it enables them to develop informed and effective strategies that address employment challenges, support economic growth, and promote social cohesion. A thorough understanding of labor

market dynamics, such as employment trends, shortages of skilled labor, wage progression, and the demographic composition of the workforce, enables the formulation of targeted policy measures that address present challenges while anticipating future labor market needs.

Trust in Economic Actors in the Czech Republic

***Ilona* Švihlíková**[1,*] **and *Dana* Junková**[1]

[1] Police Academy of the Czech Republic in Prague, Department of Management and Information Science, Faculty of Security Management, Lhotecká 559/7, 143 00 Praha, Czech Republic

Abstract

Research background: Indicators of trust and credibility are increasingly recognized as important reflections of a society's capacity for economic adaptability and resilience.
Purpose of the article: The paper presents the results of a pilot questionnaire survey aimed at mapping the attitudes of members of the Czech Police force towards the trustworthiness of various actors within the economic environment.
Methods: Methodologically, the study is based on quantitative research conducted through an anonymous questionnaire (121 respondents, carried out between February and March 2025 at the Police Academy of the Czech Republic in Prague). The collected data are analysed using descriptive statistical methods and are complemented by a comparison of different groups of police officers.
Findings & Value added: The paper provides a unique insight into the perception of the economic sphere by law enforcement authorities, with implications for building cooperation between the police and the private sector. The results can contribute to the professional discussion within the security research of the Ministry of the Interior of the Czech Republic with applicability in the application sphere within the Resilient Society priority.
The main findings show a correlation between the perception of the government to positively influence the economic situation and the respondents´ trust in the societal system as a whole. The hypothesis that "Police officers who have greater trust in the government have more optimistic expectations regarding future generations was confirmed.

Keywords: Economic actors, Police, Police force, Resilience, Trust, Trustworthiness

JEL classification: H11, D73, P16

1. Introduction

The research on trust among police officers studying at the Police Academy of the Czech Republic in Prague has been inspired by the Edelman report, which publishes a global trust barometer. The findings were considered alarming and also constituted several debates during the World Economic Forum in Davos in January 2025.

1.1 Global view on trust: findings from the Edelman Report and the Eurobarometer

The report was published with the subtitle „Crisis of Grievance Puts Pressure on Trust" (Edelman, 2025). The name of the subtitle reflects well the main findings of the report. The research was conducted in 28 countries, with more than 33,000 respondents in total. The statistical findings were confirmed by t-test with a 99% confidence level. As it was the 25th report published, there is also the possibility to observe the development in time.

The main findings constitute different pictures of trust level among countries. It is disturbing that elections fail to provide trust, mostly in the Western countries, which boast of the desirability of their democratic processes. Globalization, economic and technological issues leads to widespread insecurity. "Artificial intelligence (AI) and cyber-physical systems (CPS) are bringing revolutionary changes to the functioning of society", and at the same time, "in the post-pandemic era, inequality continues to grow globally, as for the first time in 25 years, both extreme wealth and extreme poverty have increased

[*] Corresponding author: svihlikova@polac.cz

simultaneously" (Entler, 2024, pp. 25-26). Employees trust less their employers to do what is right. This category reflects again different attitutes in different countries. Whereas in the countries with the highest growth rates (Indie, China, Indonesia) the trust is relatively high, it is the lowest in the Western countries, South Korea being the country with the smallest trust vis-à-vis employers. Other findings are no less worrisome. The belief that political leaders, business leaders and journalist lie to the public on purpose and mislead people is at an all time high. The wealthy are considered a group that does not pay their fair share and causes many problems. The most discussed issue was the proportion of people who agree that hostile activitism may be the right activity to drive change. From the age perspective it is the group aged 18-34, which is the most inclined to use such means to deliver a change to their situation.

It is the Western countries again, where people lack optimism for the future generations at most. People do not believe that the next generation will lead a better life than them. Respondents also expressed their fears of being discriminated (on the grounds of prejudice, or racism). 6 in 10 respondents reported grievances against the government, the business and the rich. Business is now more trusted than governments. Scientists and teachers were more trusted than institutional leaders.

Regarding trust there are further important sources that provide research on regular basis in standardized forms. The Eurobarometer offers regular findings regarding the trust in institutions, The Eurobarometer (2024) offers in some aspects diverging views compared to the Edelman Trust Barometer. According to the Eurobarometer the trust in EU is the highest since 2007, reaching 51 %. 69 % of respondents agree that the EU is a place of stability in a troubled world. 44 % Europeans believe that the highest positive benefit for their lives comes from ensuring peace and stability.

The findings for the Czech Republic (autumn 2024) show slightly less positive expectations than the EU average. The two most important domestic economic issues were identified as costs of living and immigration. Czech respondents were more critical of the EU, national parliament and national governments. Especially the national government gained very low trust among the respondents. Czech respondents showed high attachment to their towns and the state, but relatively much lower to the EU.

1.2 Trustworthiness of the Police of the Czech Republic and other institutions according to STEM

The trust in institutions is also regularly measured by STEM, the Centre for Empirical Research. The latest report comes from May 2025. It is the repressive forces, the Police and the Army that enjoy the highest trust by the public topped only by the Czech National Bank. "The credibility of the Police Force is a topical issue in security theory and practice" (Dinušová, Sabayová, 2024). In the report from 2024, the analyst by STEM, Jiří Táborský, emphasized that the trust in institutions reflects the trust in the state and in the system as such. The Police enjoys the second-highest level of public trust, reaching 73 %. Between 2024 and 2025, trust in the police in the Czech Republic fell by one percentage point to 72 %, see Table 1 Trust in the Police of the Czech Republic and selected institutions according to STEM.

There are long-term divergencies among the institutions. The low trust in government, indicated by Eurobarometer (2025), is supported by STEM as well. There are clear political cleavages regarding the trust in the government and Parliament. The president and the Constitutional court on the other hand enjoy higher trust. As shown in Table 1 Trust in the Police of the Czech Republic and selected institutions according to STEM, the trust in EU fell to 38 %, especially because of socio-economic issues and immigration. Regarding the survey from 2024, most institutions and organizations experienced a decline in trust.

Table 1. Trust in the Police of the Czech Republic and selected institutions according to STEM

Institution	Level of trust
Police of the Czech Republic	72 %
Army of the Czech Republic	68 %
Czech government	23 %
European Union	38 %

Source: own elaboration based on STEM data (2025)

The erosion of trust especially in the vertical form (Palmisano & Sacchi, 2024; Williams, 2020; Lonardo, 2021) is disturbing, as it had and will necessarily have a political impact. Vertical trust can be

defined as trust of individuals in a hierarchical structure. An example is the trust between a subordinate and their manager, a supervisor, or an organization/instituions as a whole.

As the Czech Republic was not included in the Edelman research, we decided to conduct our research on topics connected with trust, especially focusing on economic topics. Regarding the reported high level of trust in the repressive forces (the Police) in an environment with lowering trust levels, we chose to focus especially on this group.

The Police of the Czech Republic is a unified armed security corps established by the Act of the Czech National Council dated June 21, 1991. It serves the public, protects the safety of people and property, public order, and prevents crime. It also performs tasks under the Criminal Procedure Code and other tasks in the field of internal order and security assigned to it by laws, European Union regulations, and international treaties that are part of the legal system of the Czech Republic. The Police of the Czech Republic is subordinated to the Ministry of the Interior of the Czech Republic, and with 40,203 police officers (as of January 1, 2025) it is both the largest security corps and the largest state body in the Czech Republic. "The relationship between the police and the public is not unilateral, but bilateral, so on the one hand it is formed under the influence of factors affecting the activities of the police force, quality of work and ability to fulfill certain social functions, on the other hand the general credibility, security and the economic situation and the overall situation of the citizen and the public" (Dinušová, 2020). "The rationalized myth that the police organization is evaluated according to its effectiveness in reducing crime is not confirmed by any relevant research" (Sabayova, 2021). Police officers "are both representatives of the people as well as bearers of institutionalized values" (Rothstein & Stolle, 2008).Their behavior represents an important signal to citizens about the moral standards of the society in which they live (Kydd, 2000; Delhey & Newton, 2004).

2. The objective and methods

The main aim of this article is to find out whether there are significant divergences from the findings of Edelman trust report 2025 and STEM research regarding the specific group of Police force members, as they themselves enjoy the highest level of trust by the Czech public. Based on this, the following hypothesis was formulated: "Police officers who have greater trust in the government have more optimistic expectations regarding future generations".

To gain evidence on trust related topics a questionnaire was created. The questionnaire included 24 questions. The general questions (gender, age, education, location etc.) were accompanied by the duration of the membership in the Police force. The trust questions included trust towards institutions, business representatives, journalist and media, the employers, and the system as a whole.

The respondents could express their (dis)trust in percentage points, ranging from 1 to 100%. The attitude questions were scaled as following (do you agree, do you believe) – definitely yes, rather yes, rather no, definitely no.

The questionnaire was sent to members of the Police force, who are at the same time also students at the Police academy of the Czech Republic in Prague, both in the intra-mural form and extra-mural form. There are 963 students, who are also members of the Police force. These students were sent the questionnaire. We gained 121 completed questionnaires. The research was conducted between February and March 2025 via online questionnaire and processed in early May 2025.

The evaluation methods included coding the data and using correlation analysis to identify the main relations between variables.

3. Results

The sample consisted of 121 respondents. 83% of the respondents were aged 26-45 and had secondary education (and studying at the Police academy). The majority of respondents were male (82%). The biggest group of respondents has been serving in the Police for more than 16 years. The respondents were quite equally spread among the regions of the Czech Republic, however prevailing were Prague and the region of Central Bohemia.

3.1 Trust in economic actors and trustworthiness of the societal system

The findings regarding trustworthiness revealed the following. The trust in institutions remains relatively low, with the largest group of respondents expressing trust levels of up to 25% on a scale from 1 to 100 percentage points. Figure 1. Respondent´s trust in selected economic actors demonstrates

the results. The lowest levels of trust were observed for the Czech government, while the highest level of trust was recorded for the employer (The Police of the Czech Republic).

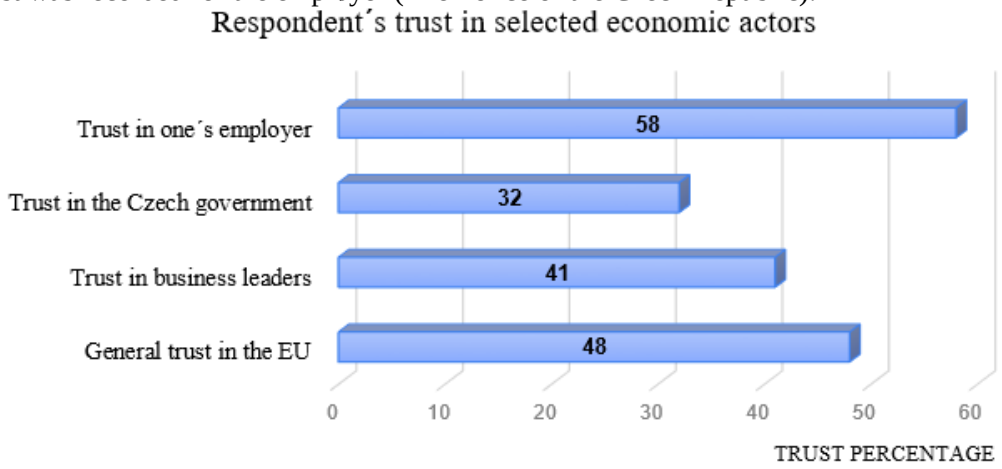

Figure 1. Respondent´s trust in selected economic actors
Source: own research (2025)

According to the above-mentioned Figure 1 Respondent´s trust in selected economic actors, the average level of trust among respondents was as follows: 58% for the employer, 48% for the EU, 41% for business leaders, and 32% for the Czech government.

As the Edelman trust barometer showed the importance of future expectations, a question regarding the living standard of the future generation was also included. The biggest group of respondents does not expect that the future generations will have the same standard (rather not).

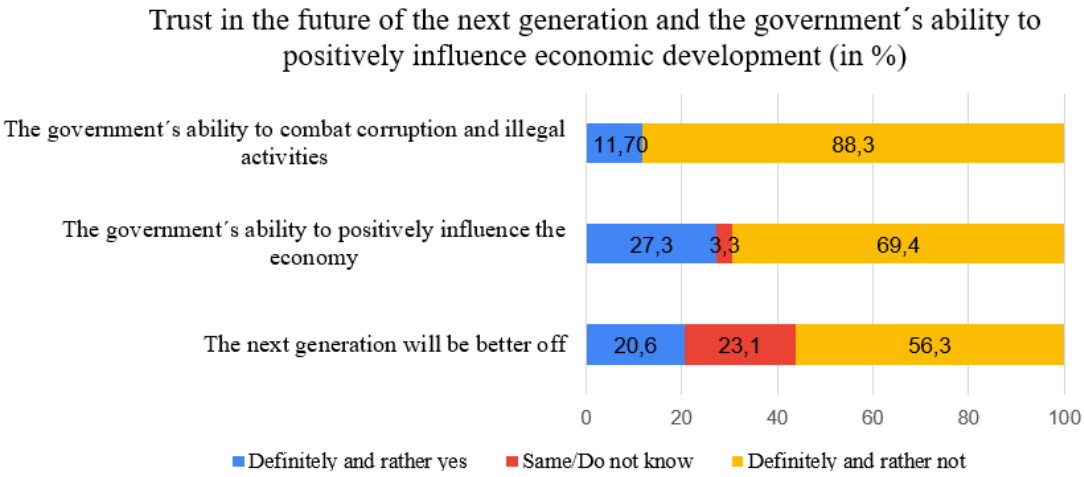

Figure 2. Respondents´ trust in the future of the next generation and government´s ability to positively influence economic development
Source: own research (2025)

According to the above-mentioned Figure 2: Respondents´trust in the future of the next generation and the government´s ability to positively influence economic development, the answers to the questions:

- Do you think the next generation will have a better future compared to the current situation? were as follows: 4,1 % of respondents answered “definitely yes”, 16,5% rather yes, 23,1% about the same as our generation, 41,4% rather no, 14,9% definitely not;
- regarding the government´s ability to positively influence the country´s economy and economic development, the responses were: 1,7% strongly agree, 25,6% rather agree, 3,3% don´t know, 32,2% rather disagree, 37,2% strongly disagree;
- regarding the government´s ability to fight corruption and illegal activities in public finances, the responses were: 11,7% rather agree, 47,5% rather disagree, 40,8% strongly disagree.

The final question contained also the issues of trustworthiness of the societal system. This time the respondents could grade (using a school grading scale 1-5; 1- excellent, 5 - insufficient). The most frequent "grade" was three, corresponding to average, followed by "4", as barely sufficient. The trustworthiness proved to be quite low towards all mentioned institutions, including the system itself.

Another important issue in the Edelman trust barometer was the inclination towards hostile activism. Our question was formulated as the understanding for protests. The majority of the respondents claimed they have no understanding for protests. This may be connected with the specific position of the repressive forces.

Although the sample may not be especially large, its benefits lie in the precise focus on the group of members of the Police of the Czech Republic. The relatively large data set enabled also correlations among important questions and categories.

3.2 Correlations, hypothesis verification, comparisons of trust

Correlations are strong among following categories:.the ability of the government to positively influence the country´s economic situation and development is connected with its ability of the government to fight corruption and illegal activites in the sphere of public finances. At the same time there is also correlation of the respondents´attitude towards the societal system as a whole. The trustworthiness of the government and the EU are correlated. Attitutes towards living standard of future generations are correlated with the respondents´attitued towards the societal system as a whole. The hypothesis was confirmed - respondents with more positive attitude towards the government and the societal system as a whole showed higher optimism towards the standard of living of future generations.

The hypothesis that "Police officers who have greater trust in the government have more optimistic expectations regarding future generations´ was confirmed. The results of the T-test for this hypothesis are as follows: t-statistic = 2,48 and p-value = 0,0168.

Table 2 Comparison of results in questions concerning trustworthiness in the Czech Republic offers comparison of trust categories by various institutions, in some case data were not available. As for the Edelman trust barometer, for illustration purposes Germany was chosen, as the Czech Republic was not included in the sample of countries. Due to relatively cultural vicinity to Germany the data are presented in the table, although interpretation should be conducted with caution. All survey share low trust in the government, which may be a connected with socio-economic situation. The data collected from the Police academy students show they have the highest trust in EU compared to other surveys (STEM and Eurobarometer). The time span overlaps, as all surveys were conducted in approximately the same time period.

Table 2. Comparison of results in questions concerning trustworthiness in the Czech Republic

Institution/Level of trust	**Edelman/Germany**	**STEM/Czech Republic**	**Eurobarometer/Czech Republic**	**Respondents at the Police academy of the Czech Repulic in Prague**
Data collected in	**Autumn 2024**	**April 2025**	**Spring 2025**	**February – April 2025**
The Government	35	23	29	32
The European Union	No data	39	43	48
Employer	69	No data	No data	58
Better prospects for the future generation	14	No data	No data	21
Business sphere	45	No data	No data	41

Source: own elaboration (based on own research, Edelman, STEM, Eurobarometer)

4. Discussion

The conducted survey among the members of the Police of the Czech Republic studying at the Police Academy of the Czech Republic in Prague offered some interesting results. The main findings show a correlation among the ability of the government to positively influence the economy, the fight against corruption and illegal activities and the attitude towards the societal system. Respondents viewing

positively the societal system are inclined to expect more positive results from the government, and also show more optimism towards future generations.

This pilot study provided important insights into the level of trust among police officers of the Police of the Czech Republic. Although the final sample consisted of 121 respondents out of 963 police officers contacted – representing only a small proportion of the overall police force – the targeted focus on police officers as a professional group offers a unique perspective.

The trust in government roughly corresponds to larger and more representative surveys like STEM and Eurobarometer, which were conducted in the same time period. It suggests that there are different cleavages determining the trust in the government than being a member of the police force. Further research, including the political preferences of the respondents is necessary to gain more information.

The authors acknowledge the limitations associated with this modest sample size and recognize that the findings may not fully reflect the views of the broader body of police officers in the Czech Republic. Moreover, the predominance of male respondents (82%) and experienced officers (more than 16 years of service) might have influenced the results towards a more positive evaluation of their own employer, i.e., the Police of the Czech Republic. Therefore, the results should be interpreted with caution and viewed as preliminary, with further research using a larger and more representative sample recommended. Future research plans regarding the highly important topic of trust thus include in-depth interviews, semi-structured interviews and larger sample questionnaires. Recent findings show, that there may be a link between the specific demands of a job and individual attitudes (Selenko, Schilbach, Brieger, Van Hootegem & De Witte, 2025), as police officers do not operate in a social vacuum. For example, Van Droogenbroeck, Kutnjak Ivkovic, and Spruyt (2022), in their large-scale study among Belgian police officers, found, that certain high-risk occupations, involving significant physical or psychological threats are associated with higher levels of ethnic prejudice, authoritarianism, and social dominance orientation. Although the number of such studies remains limited, they indicate that some professional environments – such as police work – may function as so-called “strong situations,” shaping attitudes and behaviors in specific ways and reducing the influence of personality traits (Cooper Withey, 2009). This perspective may be useful in further research on the mechanisms behind trust formation and attitudes among members of the Police of the Czech Republic.

Conclusion

The article was inspired by alarming findings of the Edelman trust barometer, which showed decreasing levels of horizontal trust especially among Western societies. As the police force has been enjoying high levels of public trust in the Czech Republic long term, they were chosen as the preferable sample of research. The survey conducted during February – April 2025 among the members of the Police of the Czech Republic at the Police Academy of the Czech Republic in Prague showed many interesting findings. A totl of 121 questionnaires were processed, using the method of coding and correlation.

The results indicate that members of the Police of the Czech Republic, even within this specific target group, share a low level of trust in key public institutions, particularly in the government. The hypothesis “Police officers who have greater trust in the government have more optimistic expectations regarding future generations” stated in this article was confirmed – respondents with positive attitudes towards the government´s capabilities showed higher optimism towards the living standard of future generations.

The survey also showed that the level of trust towards the government corresponds to levels gained by surveys conducted by STEM and Eurobarometer, where the time period overlaps.

The results highlight the need for a deeper analysis of trust within state security forces and the implications for their professional and civic attitudes.Further research will include larger samples of members of the Police of the Czech Republic, as well as in-depth interviews and semi-structured interviews.

Abstract

Research background: This paper examines the theoretical foundations for applying social responsibility in market economies, the development of CSR concepts, their characteristics and principles, the benefits of CSR and sustainable development. The healthcare sector, in particular, holds significant potential for advancing sustainability through targeted operational and policy interventions. Paper addresses current challenges related to the implementation of social responsibility in organizations operating within a market economy, with a specific focus on Slovakia, where the concept is still developing.
Purpose of the article: The aim of this paper is to analyze the application of social responsibility in organizations under market economy conditions and to propose measures to improve organizational responsibility in Slovakia.
Methods: Primary data was collected via a two-part questionnaire. A total of 62 respondents from 62 organizations in Slovakia participated in the study. The results were analyzed using advanced statistical methods in the Statistics 12 software, particularly the Kruskal-Wallis test, to verify two hypotheses: (1) that larger organizations achieve a higher social responsibility index than smaller ones, and (2) that organizations in the industrial sector outperform others in CSR performance.
Findings & Value added: The findings highlight size as a primary determinant of CSR performance, likely due to greater resources, formalized systems, and compliance incentives in large organizations. Smaller enterprises, often resource-constrained, lag behind in structured CSR implementation. This supports the argument that CSR frameworks and incentives need tailoring based on organizational capacity rather than industry type. The added value of this research lies in its empirical contribution to the understanding of CSR dynamics in transitional economies. Based on the findings, the research results will be beneficial for work not only in business and industry, but also in healthcare facilities and will also help in setting up processes when working with employees.

1. Introduction

In recent years, the regulation of business, public oversight of business outcomes, and their environmental impact have been increasingly discussed due to the expanding role of business in social development and growing expectations for transparency. Scholars such as Albareda (2007), Bowen (1953), Bartol (2008), Davis (1967), Carroll (1991), Carty (2002), Kotler (2005, 2013), Porter (2003),

* Corresponding author: eva.benkova@unipo.sk

Robert (2008), and Weber (2008) have explored the relationships between government, business, and society.

Key international CSR initiatives emerged in the 1990s, notably the UN Global Compact**,** which promotes ten principles, including support for human rights, environmental protection, anti-corruption, and non-discrimination (United Nations Global Compact, 2022).

1.1 Corporate social responsibility as a business concept in the modern era

The concept of corporate social responsibility (CSR) began to take shape in the 1960s (Skrynkovskyi, Kostiuk, Semchuk., Koropetskyi, 2016), evolving into a multi-dimensional framework by the 21st century. Today, CSR encompasses the stakeholder approach, corporate social initiatives, and business ethics. ESG reporting is increasingly recognized as a key element of corporate legitimacy in both Central and Eastern Europe and the healthcare sector **(**Hąbek & Wolniak, 2021; Trapp, 2023**).**

CSR is defined in various ways and can be analyzed through the lenses of EU policy, marketing strategy, or economic theory—as a means of profit generation. From the non-profit perspective, the theory of trust frames CSR as a mechanism that enhances public confidence in organizations compared to other less reliable sectors (Skovajsa, 2010).

CSR is broadly recognized as an ethical responsibility toward stakeholders, while also reflecting the broader societal impact of corporate behavior. Ideally, CSR represents "the responsibility of organizations to be ethical and accountable to the needs of their business as well as to the needs of stakeholders" (Kaufmann, 2014). From an economic perspective, Kotler and Keller (2013) describe socially responsible marketing as grounded in ethical, legal, and socially beneficial behavior. During crises, organizations tend to shift from traditional quality management toward anti-crisis and socially-oriented management concepts (Antoniuk, 2019).

Among the three dominant global management models—Anglo-American, Japanese, and German—the German and Japanese models, which emphasize social values, trust, and cultural cohesion, have gained prominence during global economic crises (Bochko, 2020). With growing pressure from investors, consumers, and regulatory bodies, CSR will likely become a standardized benchmark for long-term organizational legitimacy and competitiveness. As environmental and social criteria become embedded in business strategy and reporting (e.g., via the EU's CSRD Directive), the capacity of smaller firms and sector-specific institutions such as hospitals to adapt will require active public and private sector support.

The healthcare sector, in particular, faces unique operational and ethical challenges, making the implementation of CSR practices essential for long-term sustainability. Meyer et al. (2017) show that CSR strategies in healthcare can improve institutional trust and patient satisfaction. Kislinger and Richter (2020) demonstrate that stakeholder engagement and transparency in hospitals correlate with improved employee retention and public perception. Finally, Popa et al. (2019) argue that sustainability reporting and CSR adoption in public hospitals contribute to more efficient resource use and social accountability.

Recent scholarship has expanded CSR understanding across geographic and cultural contexts. For example, Aguinis and Glavas (2012) provide an integrative framework on CSR's psychological and organizational mechanisms; Jamali and Karam (2018) explore CSR in developing countries as an emerging research field; Maon et al. (2010) examine the organizational stages of CSR development; and Scherer and Palazzo (2011) highlight the political role of corporations in global governance.

2. Methodology for analysing the application of corporate social responsibility

The aim of this paper is to analyze the application of social responsibility in organizations under market economy conditions and to propose measures to improve organizational responsibility in Slovakia. Methods included a structured questionnaire and the application of statistical tools, particularly the Kruskal-Wallis test, to verify two hypotheses: (1) that larger organizations achieve a higher social responsibility index than smaller ones, and (2) that organizations in the industrial sector outperform others in CSR performance. Primary data was collected via a two-part questionnaire. The first part focused on determining the organization's size, industry, ownership form, headquarters region, and geographical scope—comprising five questions. The second part contained 25 questions divided into five categories: organization management, environment, labor-law relations, community

relations, and the business environment. A total of 62 respondents from 62 organizations in Slovakia participated in the study. The results were analyzed using advanced statistical methods in the Statistics 12 software.

In line with the main goal—analyzing the application of social responsibility in organizations under market economy conditions—hypotheses were tested using statistical methods with a significance level of $\alpha = 0.05$.

3. Results and evaluation of hypotheses

Hypothesis 1 – Relation to Company Size

H1: Large organizations achieve a higher value of the social responsibility index compared to smaller organizations.

To test this hypothesis, we used the Kruskal-Wallis test. The results are presented in tables and a box plot that displays the median, lower and upper quartiles, and range.

Management of the organization: The significance level achieved was $p = 0.0685$, based on the non-parametric Kruskal-Wallis ANOVA. Therefore, at the $\alpha = 5\%$ level, there is no statistically significant relationship between organization size and the social responsibility index in the area of organizational management.

Since it was not possible to confirm that larger organizations have a higher social responsibility index in management compared to smaller ones, only the graphical results for Hypothesis H1 are presented (Figure 1).

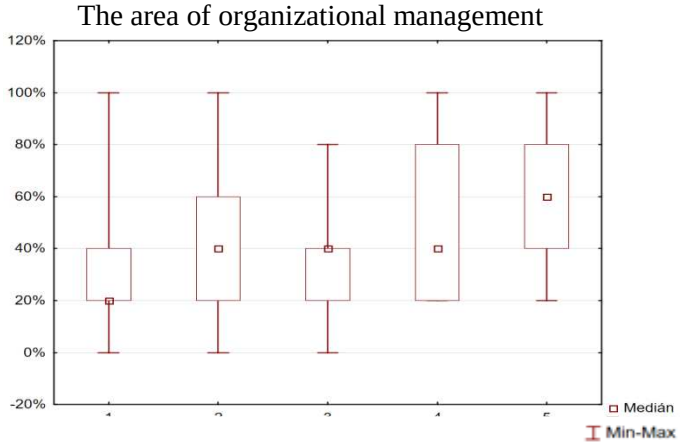

Figure 1. Results of testing hypothesis H1 in the area of organizational management

How many employees does your organization employ?
CODE: 1 – less than 10 employees, 2 – 10 to 19 employees, 3 – 20 to 49 employees, 4 – 50 to 249 employees, 5 – 250 or more employees

It follows from Graph 1 that the lowest index of social responsibility in the area of organizational management, i.e., 20%, is observed in organizations with fewer than 10 employees, while the highest index, i.e., 60%, is recorded in organizations with 250 or more employees.

Environment: We also used the Kruskal-Wallis test to examine Hypothesis H1 in the area of environmental responsibility. The results of the test are presented in Tables 1 and 2, as well as in Graph 2.

Table 1. Results of testing hypothesis H1 in the field of environment

Dependent:	Kruskal-Wallis ANOVA based on delivery; 2. ENVIRONMENT (recoded questionnaire) Independent (grouping) variable: I. How many employees does your organization employ? Kruskal-Wallis test: H (4, N= 62) =26.63207, p =0.0000

CODE: 1 – less than 10 employees, 2 – 10 to 19 employees, 3 – 20 to 49 employees, 4 – 50 to 249 employees, 5 – 250 or more employees

At the significance level of $p = 0.0000$, obtained using the non-parametric Kruskal-Wallis analysis of variance (ANOVA), we can confirm the acceptance of Hypothesis H1. The testing demonstrated a statistically significant relationship between company size and the value of the social responsibility index in the area of environmental responsibility at a significance level of $\alpha = 5\%$ (Table 1).

We are interested in identifying which groups of businesses differ from each other. For further analysis, we performed a multiple comparison of *p*-values (Table 2), which revealed a statistically significant difference in the environmental social responsibility index between organizations with fewer than 10 employees and those with 250 or more employees, as well as between organizations with 10 to 19 employees and those with 250 or more employees.

Table 2. Multiple comparison of p values for testing hypothesis H1 in the field of environment

Dependent:	Multiple comparison of p values (two-sided); 2. ENVIRONMENT (recoded questionnaire) Independent (grouping) variable: I. How many employees does your organization employ? Kruskal-Wallis test: H (4, N= 62) =26.63207, p =0.0000

CODE: 1 – less than 10 employees, 2 – 10 to 19 employees, 3 – 20 to 49 employees, 4 – 50 to 249 employees, 5 – 250 or more employees

Considering the statistically significant differences that were confirmed, we assume that large organizations have well-developed plans and programs aimed at reducing their environmental impact. These organizations implement activities focused on establishing monitoring systems to measure key environmental impacts — particularly resource usage and greenhouse gas emissions — as well as on the effective implementation of recycling programs. Compared to small and medium-sized enterprises (SMEs), large organizations are more frequently certified according to various ISO standards. This is especially important when ecological production processes require systematic monitoring and reporting — for example, in the case of reporting quantifiable reductions in greenhouse gas emissions compared to previous years.

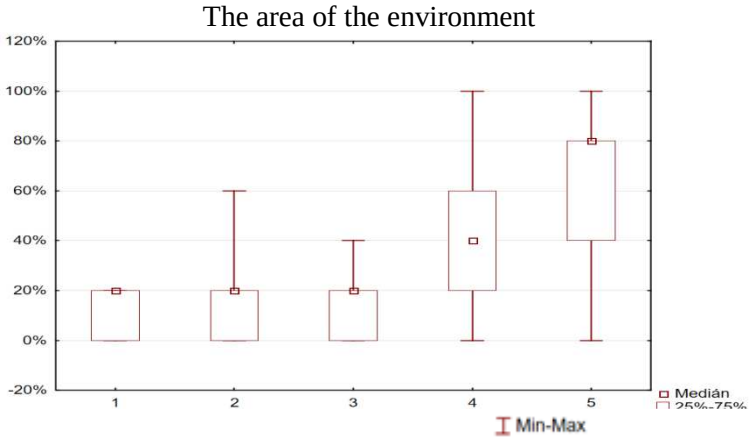

Figure 2. Results of testing hypothesis H1 in the area of the environment
Source: Own processing. Calculated by the authors using the Statistics program

How many employees does your organization employ?
CODE: 1 – less than 10 employees, 2 – 10 to 19 employees, 3 – 20 to 49 employees, 4 – 50 to 249 employees, 5 – 250 or more employees

Graph 2 shows that the lowest index of social responsibility in the area of the environment is recorded for organizations with fewer than 10 employees, as well as for those with 10–19 and 20–49 employees — all reaching an index of approximately 20%. In contrast, the highest index of social responsibility, around 80%, is achieved by organizations with 250 or more employees.

Labour-Legal Relations: At a significance level of α = 5%, we tested hypothesis H1 in the area of labour-legal relations. The results of the Kruskal-Wallis test are presented in Tables 3 and 4, as well as in Graph 3.

Table 3. Results of testing hypothesis H1 in the area of labour-legal relations

Dependent:	Kruskal-Wallis ANOVA based on delivery; 3. LABOUR RELATIONS (recoded questionnaire) Independent (grouping) variable: I. How many employees does your organization employ? Kruskal-Wallis test: H (4, N= 62) =15.45624, p =0.0038

CODE: 1 – less than 10 employees, 2 – 10 to 19 employees, 3 – 20 to 49 employees, 4 – 50 to 249 employees, 5 – 250 or more employees

The chosen test (Table 4) revealed a statistically significant difference in the value of the social responsibility index between companies with fewer than 10 employees and those with 250 or more employees in the area of labour relations. We assume that this significant difference arises from the fact that large organizations tend to focus more on evaluating the quality of human resource management. Although both large organizations and SMEs typically maintain a zero-tolerance policy for workplace accidents, the differences are mainly reflected in the existence of formal action plans — particularly those concerning human resources management and its regular evaluation, as well as official employee representation within the organization. Large organizations are also more likely to have plans to mitigate the negative effects of job reductions, along with a more rigorously developed policy for responsible behaviour toward employees.

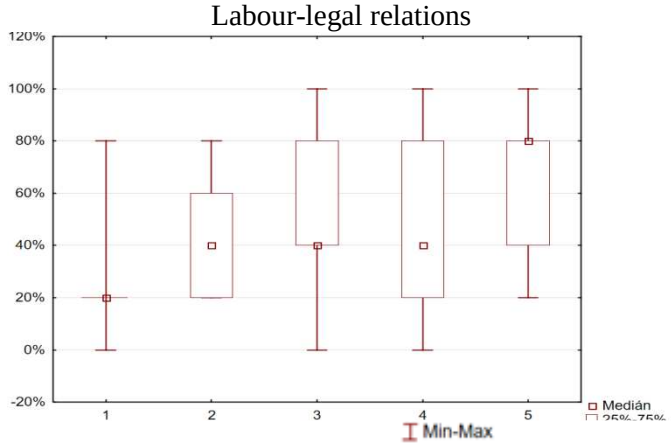

Figure 3. Results of testing hypothesis H1 in the area of Labour-legal relations

Influence of Organizational Size on CSR

The primary aim of this study was to examine whether there is a statistically significant relationship between the size of an organization—measured by the number of employees—and the achieved level of the social responsibility index in selected areas: namely, community relations, the business environment, and the overall corporate social responsibility (CSR) index. The Kruskal–Wallis non-parametric ANOVA test was used due to the relatively small sample size and the potential non-normality of the data distribution.

In the area of community relations**,** the analysis revealed a statistically significant relationship between company size and CSR index values (p = 0.0114). Organizations with 250 or more employees had the highest scores, while those with fewer than 10 or 10 to 19 employees scored significantly lower. This suggests that larger companies are more actively involved in community-oriented initiatives such as supporting civil society, cooperating with NGOs, participating in CSR-focused forums, and offering internships or training programs to develop local talent.

A similar trend was observed in the business environment domain, where the test also confirmed Hypothesis H1 with a high level of statistical significance (p = 0.0004). Organizations with fewer than 250 employees recorded the lowest CSR index scores, while larger firms achieved the highest values. This may indicate that large organizations are more likely to adopt ethical business practices, maintain internal governance structures for transparency, and integrate green procurement policies. These findings are consistent with Aguinis and Glavas (2012)**,** who highlight the role of organizational resources and institutional capacity in fostering CSR engagement.

The overall CSR index analysis yielded p = 0.0001, further supporting Hypothesis H1. The smallest organizations (under 20 employees) had the lowest scores, with CSR performance improving as organizational size increased. Firms with 250+ employees exhibited the highest levels of CSR, likely due to their structured, institutionalized approaches to managing social, environmental, and economic responsibilities—such as recycling programs, legal compliance, and internal ethics policies.

These outcomes align with the conclusions of Baumann-Pauly et al. (2013)**,** who found that larger companies are more likely to develop formal CSR strategies due to their broader stakeholder exposure and resource availability. Similarly, Gallo and Christensen (2011) emphasize that firm size significantly predicts the degree and sophistication of CSR involvement.

Hypothesis H1 was confirmed: *Larger organizations consistently achieve higher values of the social responsibility index compared to their smaller counterparts.*

Hypothesis H2: Industry-Specific CSR Differences

Hypothesis H2 posited that organizations operating in the industrial sector would achieve higher CSR index values than those in other sectors.

To test this, the Kruskal–Wallis ANOVA was applied across six dimensions: organizational management, environmental responsibility, labor-law relations, community relations, the business environment, and the overall CSR index.

In **organizational management**, the *p*-value was 0.1556, indicating no significant difference across sectors. Though the construction sector showed the highest score (80%), sectors like agriculture, transport, and business services scored much lower (20%).

For **environmental responsibility**, the *p*-value was 0.1735. The trade sector led with 30%, while agriculture, transport, and public services scored only 10%.

The **labor-law relations** category had a *p*-value of 0.2173, with trade showing the highest score (50%) and transport the lowest (10%).

In **community relations**, the *p*-value was 0.3830. The industrial sector scored up to 40%, but construction recorded a zero score.

In the **business environment** domain, the *p*-value was 0.4210, showing no significant variation. The industrial sector achieved 40%, but agriculture and construction remained low at 20%.

For the **overall CSR index**, $p = 0.1228$. The transport sector had the lowest average (14%), trade was highest (37%), and the industrial sector reached 32%.

Collectively, these results show no statistically significant differences in CSR performance by industry.

Hypothesis H2 was rejected. This outcome supports the view that organizational size, rather than industry, is a more critical determinant of CSR engagement. These results echo the findings of Jamali and Karam (2018)**,** who argue that contextual and institutional variables are stronger predictors of CSR practices than industry classification. Additionally, Miska, Stahl, and Mendenhall (2013) suggest that leadership, global CSR expectations, and organizational culture play a more influential role than sectoral norms in shaping CSR behavior.

4. Discussion

This study confirmed Hypothesis H1, showing that larger organizations consistently outperform smaller ones in all CSR domains—particularly in environmental practices ($p = 0.0000$), labor-law relations ($p = 0.0038$), community relations ($p = 0.0114$), and the business environment ($p = 0.0004$). Conversely, Hypothesis H2 was rejected: no statistically significant differences in CSR index values were observed across industry sectors ($p > 0.05$).

Key Findings:

- Small enterprises (fewer than 10 employees) demonstrate the weakest CSR performance, particularly in environmental and labor categories.
- Large organizations (250+ employees) achieve the highest CSR scores, in some cases up to 80%.
- Industry affiliation does not significantly affect CSR levels—highlighting the greater influence of organizational size and internal capacity.

Practical Implications:

These results suggest that CSR policies and support programs should be tailored by firm size rather than by sector**.** Policymakers should prioritize mechanisms that help small and medium-sized enterprises (SMEs) overcome barriers to CSR adoption, such as limited resources, lack of expertise, or regulatory burden. The healthcare sector, in particular, holds significant potential for advancing sustainability through targeted operational and policy interventions. Hospitals should prioritize energy efficiency, green procurement, and waste reduction while also engaging staff in sustainability initiatives. These measures can strengthen institutional resilience, reduce environmental impacts, and improve long-term health outcomes. To support this transformation, national health strategies should incorporate clear sustainability targets and dedicated funding schemes. In addition, hospital accreditation systems could integrate sustainability indicators to incentivize continuous improvement. Collaboration with local governments and communities can also enhance hospitals' social responsibility efforts and amplify their public health impact.

Future Research Directions and Outlook:

Looking ahead, future studies should explore:

- The longitudinal evolution of CSR practices within growing firms;
- The role of digitalization and ESG (Environmental, Social, Governance) reporting standards in CSR effectiveness;

- The cross-national variation in CSR outcomes among similar-sized firms operating under different institutional environments;
- Recommendations for the healthcare sector and hospitals in order to achieve their sustainability, particularly through the implementation of CSR strategies adapted to the specific operational, environmental, and societal challenges of the health sector.

Conclusion

With growing pressure from investors, consumers, and regulatory bodies, CSR will likely become a standardized benchmark for long-term organizational legitimacy and competitiveness. As environmental and social criteria become embedded in business strategy and reporting (e.g., via the EU's CSRD Directive), the capacity of smaller firms and sector-specific institutions such as hospitals to adapt will require active public and private sector support. Future research should also address recommendations for the healthcare sector and hospitals in order to achieve their sustainability, given their critical role in public well-being and their substantial environmental footprint. This includes investigating how hospitals can integrate CSR principles through energy efficiency, waste reduction, sustainable procurement, and stakeholder engagement.

The findings highlight size as a primary determinant of CSR performance, likely due to greater resources, formalized systems, and compliance incentives in large organizations. Smaller enterprises, often resource-constrained, lag behind in structured CSR implementation. This supports the argument that CSR frameworks and incentives need tailoring based on organizational capacity rather than industry type. The lack of industrial advantage in CSR performance suggests that external regulatory pressure or public expectations are uniformly applied or ineffective at distinguishing sector performance. Instead, firm-level strategies and resources appear more decisive.

The findings provide a basis for policymakers and managers to design more effective CSR strategies tailored to organizational size rather than industry affiliation.The healthcare sector, in particular, holds significant potential for advancing sustainability through targeted operational and policy interventions. Hospitals should prioritize energy efficiency, green procurement, and waste reduction while also engaging staff in sustainability initiatives. These measures can strengthen institutional resilience, reduce environmental impacts, and improve long-term health outcomes.

Abstract

Research background: Recent advances in digital technologies have introduced new, innovative approaches to recruitment and selection (R&S) in human resource management. Despite their growing adoption, there remains a need to empirically evaluate how these methods influence organizational outcomes, particularly candidate satisfaction, in the Slovak business environment.
Purpose of the article: The aim of the paper is to investigate the relationship between the use of innovative recruitment & selection methods and the level of satisfaction with selected candidates in Slovak enterprises.
Methods: The research was conducted in March 2025 on a sample of 153 medium-sized and large companies operating in Slovakia. Two hypotheses were tested using the chi-square test of independence to determine statistical relationships between the adoption of innovative methods and satisfaction outcomes.
Findings & Value added: The findings indicate a statistically significant association between the use of innovative recruitment methods and higher satisfaction with selected candidates. In contrast, no significant relationship was found between innovative selection methods and satisfaction levels. The study contributes to the understanding of HR digitalisation by highlighting both its practical benefits and the need for ethical and technological considerations in implementation.

Keywords: Human resources, Recruitment&selection, Innovation, Digital transformation.

JEL classification: M51, O33

1. Introduction

Organisations today are confronted with an unprecedented pace of technological advancement and continuously evolving labour market trends, which are fundamentally reshaping how they approach recruitment, selection, and talent retention. Attracting qualified professionals has become a strategic priority that directly influences a company's competitiveness. The digital age has disrupted traditional human resource management models—particularly in the domains of recruitment and selection—bringing not only new opportunities, but also significant challenges for experts in HR, occupational psychology, and technological innovation (Rashma, Jenithakarthiga, Pavithra, 2024).

Historically, both research and practice within work psychology and human resource management have placed considerable emphasis on the development of effective methods for selecting, evaluating, and integrating employees (Ryan & Ployhart, 2014; Markoulli et al., 2017).

Traditional recruitment processes typically followed a linear sequence—from identifying staffing needs through to the conclusion of an employment contract—relying heavily on static applicant databases, which were often outdated and underutilised. In recent years, however, technology has permeated virtually every aspect of this process (Woods et al., 2020), fundamentally reshaping standard practices. Innovations such as automated CV screening, advanced data analytics, and digital assessment tools are increasingly being adopted, even for the most routine recruitment procedures.

A notable development in recent years is the emergence of electronic recruitment, which preserves the structure of the traditional recruitment process while transferring it to an online environment—typically through company websites, job portals, and social media platforms. This digital shift has

[*] Corresponding author: jana.coculova@unipo.sk

considerably enhanced the efficiency of communication and candidate selection, particularly through algorithm-driven pre-screening based on qualifications. Simultaneously, organisations are increasingly prioritising proactive talent acquisition strategies, such as networking and direct outreach, in place of more passive methods of attracting candidates. Networking, in particular, has become a valuable recruitment tool, centred on the cultivation of professional relationships and the exchange of referrals. This relational approach has been shown to significantly improve the effectiveness of recruitment efforts (Tullier, 2006).

Another major driver of change is the growing integration of artificial intelligence (AI) into recruitment processes, bringing with it predictive analytics and automated decision-making capabilities. Contemporary application processing systems, such as HireVue and Pymetrics, employ video analysis and neuroscientific techniques to evaluate candidates' personality traits and cognitive abilities (Black & Van Esch, 2020). These tools are designed not only to enhance the precision of candidate assessment but also to reduce cognitive biases, thereby promoting greater objectivity in selection outcomes. Applicant Tracking Systems (ATS) further streamline recruitment by automating CV screening, identifying relevant keywords, and aggregating data from publicly available online sources—ultimately saving both time and human resources. In addition, many organisations are adopting AI-powered chatbots to provide real-time feedback to applicants, while simultaneously alleviating HR departments of repetitive administrative tasks (Upadhyay & Khandelwal, 2018).

In addition, novel approaches such as the gamification of selection processes and game-based assessment (GBA) are gaining traction, reshaping conventional testing methods into more interactive and dynamic formats. These tools immerse candidates in simulated environments, allowing for the observation of their responses to realistic workplace scenarios. This not only enhances candidate engagement but also improves the ecological validity of the data collected (Georgiou et al., 2019). Furthermore, gamification contributes to the organisation's appeal, particularly among younger applicants who increasingly expect a technologically advanced and interactive recruitment experience (Georgiou & Nikolaou, 2020).

However, the transformation of employee selection processes also presents a range of new challenges. While technology undoubtedly enhances efficiency, concerns persist regarding the validity and ethical implications of its use. For instance, although psychometric testing is increasingly common, it has been criticised for the potential over-objectification of human abilities (Michell, 2000). Equally significant is the ongoing need for the development and maintenance of applicant databases, which demands substantial investment in data management and cybersecurity (Goleji et al., 2023). In parallel, corporate career pages are assuming a more prominent role in employer branding. Visual content—such as employee testimonial videos and detailed portrayals of the working environment—not only enhances transparency but also helps to build trust among prospective applicants (Lievens & Slaughter, 2016). Moreover, these platforms enable the analytical tracking of job seeker engagement, website traffic, and interactions with content, thereby supporting the continuous optimisation of recruitment strategies.

Despite the growing array of innovative tools, empirical research on the effectiveness of e-recruitment methods remains relatively limited. As such, the selection of recruitment technologies should be guided not only by their technical capabilities, but also by the organisation's strategic objectives and cultural context. A critical factor in the successful implementation of digital tools is their alignment with the broader HR strategy, alongside ongoing evaluation of their impact on the efficiency, fairness, and ethical integrity of the selection process (Koivunen et al., 2022).

Digitisation is fundamentally reshaping the paradigm of human resource management. The future of recruitment & selection will depend on organisations' ability to integrate emerging technologies in a flexible manner, while preserving the human element in decision-making. Sustainable and effective talent acquisition strategies will be shaped by continuous outcome evaluation, procedural transparency, and a willingness to engage in interdisciplinary collaboration across fields such as information technology, data science, and behavioural economics.

2. Methods

A survey was carried out to examine the current use of modern recruitment & selection methods in Slovak organisations. One of the secondary aims of the study was to analyse satisfaction with candidates in relation to the use of innovative approaches within the recruitment and selection (R&S) process. The

research targeted companies operating in the Slovak Republic that qualified as medium-sized or large enterprises (employing 250 or more people), where a higher frequency of R&S activity could reasonably be expected. Data were collected through a questionnaire administered in March 2025. The sample consisted of 153 companies, which were categorised based on the independent variable: whether or not they made use of selected innovative R&S methods. As R&S represent distinct stages within the overall R&S process, the analysis treated them separately. The independent variable was defined as the use or non-use of innovative methods in each respective phase.

The paper presents the results of hypothesis testing conducted using the chi-square test of independence. Two hypotheses were examined:

H1: There is a statistically significant association between the use of innovative recruitment methods and the level of satisfaction with the selected candidates by recruitment.

H2: There is a statistically significant association between the use of innovative selection methods and the level of satisfaction with the selected candidates.

3. Results

One of the objectives of the survey, which focused on the use of innovative recruitment and selection (R&S) methods, was to determine whether companies employing such methods report higher levels of satisfaction with the applicants they ultimately select.

The first phase of the research examined innovative approaches used in the recruitment stage, that is, methods aimed at attracting suitable job candidates. Reaching a sufficient number of applicants who meet the desired criteria represents the initial step in securing high-quality hires. Although a wide range of methods is available for attracting applicants, the study focused on selected modern and innovative approaches. These included: (1) employer branding, (2) social recruiting (engaging candidates via social media platforms), (3) the use of mobile applications for initial contact (e.g., Messenger, WhatsApp), (4) experience-based recruiting, and (5) the use of artificial intelligence to analyse candidate profiles.

The results indicated that, out of the 153 participating organisations, 82 reported using at least one of the innovative methods listed, while 71 had no experience with any of them. The extent to which each of these methods is applied during the recruitment phase is illustrated in Figure 1.

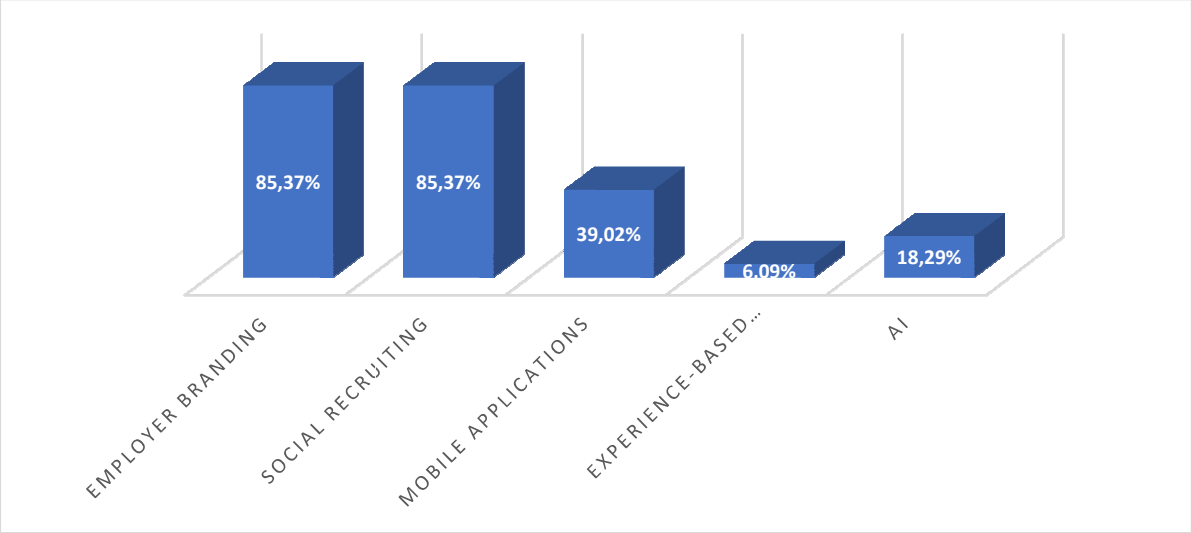

Figure 1. Use of innovative methods for recruiting employees
Source: own processing (2025)

H1: We hypothesise a statistically significant association between the use of innovative recruitment methods and the level of satisfaction with the selected candidates by recruitment.

Out of the total 153 companies participating in the study, 53.59% reported experience with at least one innovative recruitment method, while 46.40% had no experience with these methods. Table 1 presents the levels of satisfaction with the candidates invited to selection procedures over the past 12 months.

Table 1. Comparison of satisfaction with selected candidates according to the use of innovative recruitment methods

	Very satisfied	Satisfied	Neutral	Dissatisfied	Very dissatisfied
Yes	64.6%	24.4%	0.00%	11.0%	0.00%
No	49.3%	18.3%	22.5%	9.90%	0.00%

Source: own processing (2025)

The results of hypothesis H1 testing are shown in Table 2.

Table 2. H1 testing

Test type	χ^2 (chi-square)	df	p-value	Significance
Chi-square test of independence	20.73	3	0.00012	**p < 0.001**

Source: own processing (2025)

Based on the test results, H1 is accepted, confirming that companies employing innovative recruitment methods report higher levels of satisfaction compared to those not using any such methods.

The second part of the study examined innovative employee selection methods designed to evaluate candidates' required attributes. The research focused on Online Assessment Centres, video interviewing, nonverbal analysis, gamification, and AI-driven predictive analysis. Among the 153 companies surveyed, 33.98% utilised one or more of these methods, while 66.02% did not. Figure 2 illustrates the frequency of use for each of the innovative candidate selection methods.

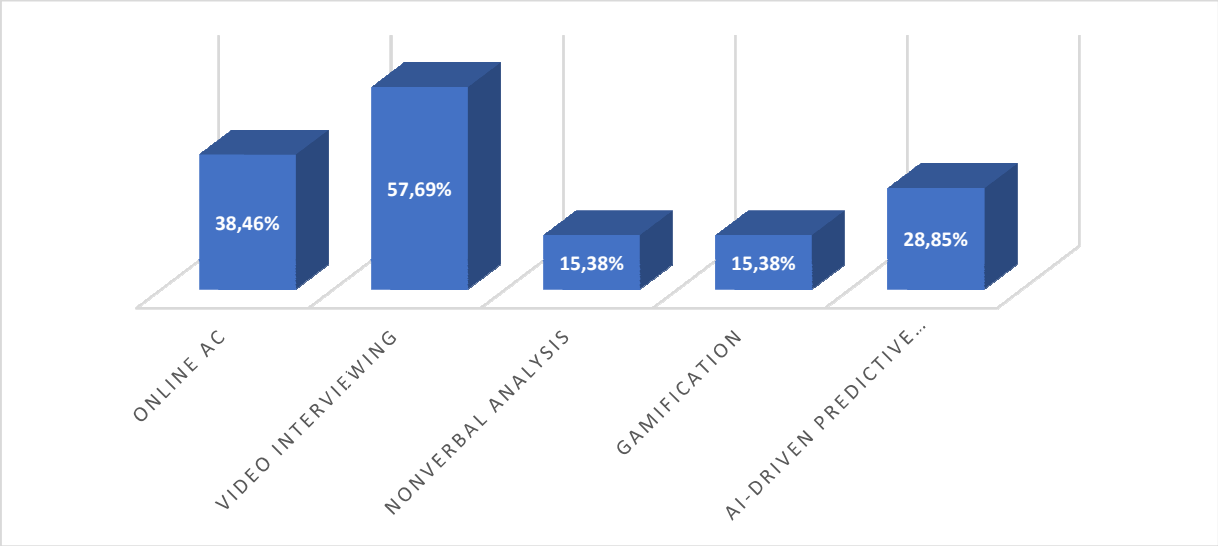

Figure 2. Use of innovative methods for selecting employees
Source: own processing (2025)

H2: We hypothesise a statistically significant association between the use of innovative selection methods and the level of satisfaction with the selected candidates.

Among the 153 companies surveyed, 33.98% reported experience with at least one innovative selection method, while 66.02% had no such experience. Table 3 presents a comparison of company satisfaction with selected candidates over the past 12 months, analysed in relation to the use of innovative staff selection methods.

Table 3. Comparison of company satisfaction with selected candidates by use of innovative staff selection methods

	Very satisfied	Satisfied	Neutral	Dissatisfied	Very dissatisfied
Yes (n=52)	27.5%	5.2%	0.7%	0.7%	0.0%
No (n=101)	47.7%	13.1%	2.0%	2.0%	1.3%

Source: own processing (2025)

The results of hypothesis H2 testing are shown in Table 4.

Table 4. H2 testing

Test type	χ^2 (chi-square)	df	p-value	Significance
Chi-square test of independence	2.01	4	0.733	n.s. (not significant)

Source: own processing (2025)

Based on the statistical analysis, hypothesis H2 is rejected, indicating no significant correlation between the use of innovative employee selection methods and satisfaction with the chosen candidates.

4. Discussion

The findings reveal that employer branding and social recruiting are the most widely adopted methods. Employer branding serves as a contemporary HR marketing tool, employed not only to attract new employees but also as part of a broader strategic effort to consistently cultivate a positive reputation among both current and prospective talent. It represents a defining characteristic of modern organisations that recognise the importance of articulating their approach to human resources. Such efforts can influence not only prospective "freelance" candidates but also existing employees who may be contemplating a change of employer. This positions employer branding as one of the most important innovative methods for attracting talented candidates. Social recruiting is also widely employed, enabling companies to target specific candidate groups through sophisticated marketing techniques. Mobile applications for initial contact have become a standard communication tool, significantly facilitating and accelerating interactions, and their use is expected to increase. The use of artificial intelligence to analyse candidate profiles is still relatively new, which could explain its comparatively low adoption rate. Experience-based recruiting is a highly specialised method, applicable only to certain job roles, and is therefore rarely used within our context.

Video interviews are the most commonly used method, likely due to their ability to replace traditional face-to-face interviews while being conducted online, which also simplifies scheduling. Online Assessment Centres represent another innovative approach, valued for their ease of organisation and their capacity to assess candidates' technical skills. Predictive analysis powered by AI marks a significant advancement in candidate evaluation, as it is not only easier to implement than previous methods but also enhances objectivity and accuracy in selecting the most suitable candidates.

The results show that companies using innovative recruitment methods report higher satisfaction with selected candidates (64.6% very satisfied) compared to those using traditional approaches (49.3%). This difference was statistically significant ($\chi^2 = 20.73$, $p < 0.001$), supporting Hypothesis H1. In contrast, the use of innovative selection methods (e.g., video interviews, online assessment centres, AI tools) did not significantly impact satisfaction levels ($\chi^2 = 2.01$, $p = 0.733$), leading to the rejection of Hypothesis H2.

Conclusion

The findings of this study underscore the value of innovative approaches primarily during the recruitment stage, where a clear positive impact on candidate satisfaction was identified. Techniques such as employer branding and social recruiting emerged as effective strategies for attracting high-quality applicants. In contrast, the role of innovation in the employee selection phase remains inconclusive, possibly reflecting its limited adoption or inconsistent application in practice. These results highlight the importance of carefully aligning digital recruitment tools with an organization's overall strategy and core

values. Moreover, maintaining the human element in selection processes is crucial, as an overreliance on technology risks compromising the personalized evaluation of candidates. Future research should place greater emphasis on the qualitative aspects of employee selection and investigate the long-term effects of modern recruitment methods on employee retention and job performance.

Work Engagement Among Healthcare Professionals: A Comparative Analysis of Key Influencing Factors

***Jana* Cocuľová**[1,*] **and *Veronika* Škerháková**[1]

[1] University of Prešov in Prešov, Department of Management, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: This paper examines the work engagement of healthcare personnel, a critical determinant of healthcare quality, staff performance, and patient satisfaction. Given the escalating demands and persistent staff turnover, exacerbated by the recent COVID-19 pandemic, understanding the drivers of engagement has become paramount

Purpose of the article: The purpose of this article is to critically analyse theoretical constructs and empirical findings pertaining to healthcare staff engagement. We achieve this through a secondary analysis of three distinct empirical studies presented herein. Our objective is to delineate shared factors that foster engagement and to propose actionable recommendations for healthcare management.

Methods: This paper synthesises established theoretical frameworks with a secondary analysis of three distinct quantitative studies. These comprise: (1) a systematic meta-analysis, (2) a study conducted within Slovenian primary healthcare, and (3) a study focusing on hospital nurses in Thailand. Crucially, all included studies utilised the standardised Utrecht Work Engagement Scale (UWES) and other validated questionnaires for their measurements.

Findings & Value added: Our findings indicate that engagement is primarily shaped by leadership quality, working conditions, team climate, and individual resilience. We also observed a strong negative correlation between engagement and burnout syndrome. Ultimately, fostering engagement through targeted organisational interventions can lead to enhanced staff satisfaction, diminished turnover rates, and a demonstrable improvement in healthcare quality

Keywords: Engagement, Health sector, Healthcare quality

JEL classification: J28, M12

1. Introduction

Whilst numerous authors have sought to define employee engagement, a singularly clear and universally accepted definition remains elusive, largely owing to its relatively nascent conceptualisation. Kahn (1990), widely credited with coining the term, initially characterised engagement as the degree of commitment and involvement exhibited by employees within their employing organisation. A similar understanding is advanced by Robinson et al. (2004), who describe engagement as "the positive attitude of employees toward their organisation and its value." They further elaborate that engaged employees demonstrate an acute awareness of the broader business context and readily collaborate with colleagues to enhance organisational performance. Rashid et al. (2011) contend that achieving a competitive advantage is imperative for any enterprise, positing that employee engagement represents the optimal strategy for securing such an edge. They suggest that fostering engagement can be achieved through various mechanisms, including involving employees in decision-making processes, promoting collegial cooperation, and implementing individual performance appraisals

1.1 Theoretical Basis of the Concept of Engagement

The organisation itself plays a pivotal role, as it must actively cultivate and sustain employee engagement, thereby necessitating a reciprocal relationship between employer and employee. A study

[*] Corresponding author: jana.coculova@unipo.sk

undertaken by Jung et al. (2021) empirically corroborated the link between employee engagement and the propensity for staff turnover. Their findings indicated that heightened employee engagement positively influences productivity, work efficiency, and, ultimately, the overall success of an organisation.

Indeed, employee engagement serves as a salient positive indicator for a company's ability to achieve its strategic objectives. The prevailing style of employee management is also of considerable import, with Kumar and Israel (2012) asserting its substantial impact on engagement. Furthermore, the provision of benefits, the strengthening of professional roles, the offering of training and development opportunities, and the creation of both professional networks and avenues for leisure pursuits are all intrinsically linked to fostering employee engagement.

While employee engagement is extensively discussed within academic discourse as a mechanism for mitigating staff turnover, a precise, universally accepted definition and a clear demarcation of its core determinants remain somewhat elusive. Chanan (2021) conceptualises employee engagement as a workforce that is both loyal and fully participating, readily embracing organisational principles for motives extending beyond conventional incentives. Furthermore, Ranjan (2014) posits that a continuous, bilateral flow of communication is indispensable for cultivating and sustaining robust employee-employer relationships. He stresses the effective role of internal communication in fostering engagement, adding that any organisation aspiring to expand, retain its clientele, and maintain an engaged and satisfied workforce simply cannot afford to overlook internal communication as a pivotal aspect of effective human resource management.

Employee engagement signifies an emotional commitment an employee feels towards their organisation and its objectives. The endeavour to engage, motivate, and secure employee loyalty has long been a key concern for management across many companies. When staff demonstrate such commitment or loyalty, it yields a range of positive outcomes, as highlighted by Budriene and Diskiene (2020):

- A sense of control over their work environment.
- Confidence in the future stability of the organisation.
- Self-assurance in their capacity to instigate positive change within the organisation.
- An eagerness to learn and experiment.
- A strong inclination to remain with the company, leading to lower staff turnover and higher retention rates.

Many leading consulting firms, including Accenture, Concours, Gallup, Hewitt, Mercer, Towers Perrin, and Watson Wyatt, have undertaken extensive surveys on engagement. Drawing upon these findings, Storey et al. (2008) identified seven common factors that significantly foster employee engagement:

- Vision: A clearly articulated organisational purpose for the future instils a sense of pride among its employees.
- Opportunity: The provision of new work opportunities allows for both personal and professional development.
- Motivation: Offering a diverse range of tangible and intangible benefits acts as a powerful stimulus for engagement.
- Meaning: Emphasising the significance and importance of an individual´s contribution to the work.
- Community: Cultivating a healthy work environment and a positive corporate culture.
- Communication: Ensuring an effective, bidirectional flow of information throughout the organisation.
- Experimentation: Implementing flexible policies regarding working hours, dress codes, and other arrangements, designed to meet the needs of both the organisation and its employees.

Each of these factors offers a suite of options that leaders can leverage to enhance employee engagement. It´s crucial to recognise that individual employees may place varying emphasis on each factor. Furthermore, an employee´s perception of these factors´ importance can evolve throughout their career; for instance, early in their career, incentives or financial reward might hold greater significance than other elements. Collectively, these seven elements can form an employee value proposition, representing the holistic return employees receive in exchange for their commitment to their employer.

1.2 Engagement and its Importance in the Healthcare Sector

Employee engagement is demonstrably crucial for organisational success, particularly within the service sector where workers are directly responsible for fulfilling consumer needs (Bailey 2022).

In healthcare, effective human resource management necessitates considerable supper and commitment from employees who are expected to undertake continuous skills development and training throughout their careers to deliver a high standard of service in patient care environments. Consequently, achieving a high level of engagement stands as a strategic objective for organizations across numerous industries, not least within healhtcare.

Engaged employees exhibit dedication to their employer, express satisfaction with their work, and are prepared to exert discretionary effort to achieve the organization's objectives. Research indicates that engagement profoundly influences other critical human resource outcomes, including staff retention, job performance, absenteeism, and – indirectly, through the enhacement of employer reputation – recruitment efforts (Gibbons and Schutt 2010).

It is clear that managing issues related to healthcare personnel has become considerably more complex since the COVID-19 pandemic. Research examining employee engagement during crises indicates that traditional forms of remuneration, such as bonuses and merit-based reward, are often employed to boost engagement (Olds et al. 2022). However, it is crucial to acknowledge other significant factors that are proving essential for developing and retaining a modern workforce. These include a better work-life balance, opportunities for career growth, and training specifically designed to prepare employees for crisis situations (Gabriel and Auguinis 2021).Therefore, healthcare organizations must implement actions and measures that actively promote employee engagement and recognise the factors influencing and supporting both the mental and physical well-being of their workforce.

Historically, the focus has predominantly been on cultivation "healthier" workplaces. However, contemporary imperatives demand a comprehensive, strategically focused approach to measuring and reporting on the quality of the healthcare work environment. This signifies a crucial paradigm shift toward programmes that champion employee integration within a holistic framework for enhancing the quality of healthcare provision.

Furthermore, there is increasing discourse surrounding the positive correlation between staff satisfaction and patient satisfaction. This is underscored, for instance, by research demonstrating robust links between employee engagement and client (patient) satisfaction. Indeed, a number of studies in the field of healthcare management suggest that managers can demonstrably elevate the standard of patient care by fostering greater staff satisfaction and engagement (Collins et al. 2008; Sikorska-Simmons 2006).

2. Methods

The primary aim of this paper is to analyse and compare current knowledge regarding healthcare staff engagement. We achieve this through an examination of selected empirical studies that specifically investigate its connections to workplace factors, burnout syndrome, and individual personality traits, such as resilience. Our objective is to identify recurring determinants of engagement and to formulate practical recommendations for healthcare management.

Following this theoretical framework, we conducted a secondary analysis of selected empirical studies examining the work engagement of healthcare personnel across diverse contexts. Our selection process was targeted, focusing on quantitive research published in peer-reviewed scientific journals after 2020. These studies had to meet the following criteria:

- The target group comprised heatlhcare workers, with a particular emphasis on nurses.
- Engagement was measured using standardised tools, such as the Utrech Work Engagement Scale (UWES)
- The research design and statistical analysis were clearly articulated.

From the final selection, we chose three representative studies, each originating from a distinct geographical and systemic context; an international meta-analysis by Aguiar-Diaz et al. (2023), national research from Slovenia by Szilvassy & Širok (2022), and a study from Thailand by Nantsupawat et al. (2024). national research from Slovenia by Szilvassy & Širok (2022), and a study from Thailand by Nantsupawat et al. (2024).

3. Results

The first study subjected to our analysis is the meta-analysis by Aguiar-Díaz et al. (2023). This particular study aimed to synthesise existing research exploring the level of work engagement and its association with burnout among nurses. The authors specifically focused on three principal dimensions for each phenomenon: in the case of burnout, these were emotional exhaustion, depersonalisation, and reduced personal accomplishment, whilst work engagement was assessed via vigour, dedication, and absorption.

This particular study drew its evidence from a search of the PubMed and Scopus databased. It incorporated nine quantitative studies that adhered to stringent selection criteria, including the mandatory use of validated measurement tools such as the Maslach Burnout Inventory (MBI) and the Utrecht Work Engagement Scale (UWES).

The finding unequivocally confirm a strong negative correlation between work engagement and burnout. This suggests that as nurses´ work engagement increases, the likelihood of experiencing burnout syndrome significantly decreases. The most pronounces protective effect was observed in the "vigour" dimension of engagement when contrasted with "emotional exhaustion" – components that, perhaps unsurprisingly, are the most prominent characteristics distinguishing engaged from burned-out employees.

The authors also pinpointed several factors acting as mediators in this relationship. At an individual level, these primarily include personal resources like resilience, self-confidence, and effective coping strategies. On an organisational level, support from management, the autonomy to make decisions regarding one's own work, and a favourable work environment emerged as significant. According to the authors, these factors not only have the potential to boost engagement but also serve as crucial preventative measures against burnout.

The work engagement of healthcare personnel within the primary healthcare context was the focus of a study by Szilvassy and Širok (2022). Their research was fundamentally driven by the critical need to better understand the factors influencing employee motivation, retention, and indeed, overall performance in this sector. The study specifically aimed to ascertain the level of work engagement prevalent among staff in public primary healthcare facilities and to meticulously analyse how this engagement correlated with various selected aspects of their work environment.

The authors particularly honed in on the quality of leadership, the standard of internal communication, the efficacy of work organization, and the readily available support from the broader organization. The research itself was conducted using a robust, standardised questionnaire, which crucially incorporated the Utrecht Work Engagement Scale (UWES) to measure the three key dimensions of engagement (vigour, dedication, and absorption), alongside further questions meticulously designed to map the perceived quality of the work environment.

Data was collected within a representative sample of employees working in the Slovenian public health system. The findings corroborated that engagement is significantly shaped by the calibre of the organisational environment. The salient determinants of heightened engagemet were identified as a congenial work atmosphere, unambiguously defined work tasks, readily available managerial support, and transparent, reciprocal communication. Conversely, substandard management and deficient work organisation were demonstrably linked to a decrement in engagement and diminished satisfaction with servies.

The topic of the nexus between engagement and the mental well-being of healthcare personnel is further elucidated in a study by Nantsupawat et al. (2024), published in BMC Nursing. The topic of the nexus between engagement and the mental well-being of healthcare personnel is further elucidated in a study by Nantsupawat et al. (2024), published in BMC Nursing. This research, conducted on a sample of Thai hospital nurses, primarily aimed to explore the interrelationships between resilience, burnout syndrome, and work engagement.

A particular emphasis was placed on identifying factors that might serve as protective mechanisms within a demanding work environment. To collet the requisite data, three standardised questionnaires were employed: the Connor-Davidson Resilience Scale (CD-RISC-10) for the measurement of psychological resilience; the Maslach Burnout Inventory (MBI) for the assessment of burnout across its three dimensions; and the Utrecht Work Engagement Scale (UWES-9) for the measurement of work engagement. Data analysis revealed a significant negative correlation between resilience and burnout, alongside a positive correlation with engagement. This indicates that nurses exhibiting higher levels of

psychological resilience were less susceptible to emotional exhaustion and, concomitantly, demonstrated greater activity, commitment, and absorption in their work. Furthermore, a negative relationship between engagement and burnout was substantiated, a finding consistent with the broader body of existing literature.

4. Discussion

An analysis of selected studies confirms that the work engagement of healthcare personnel is complexly conditioned by both personal and organisational factors. While individual characteristics such as mental resilience, coping strategies, and self-confidence play a protective role, organisational conditions—especially the quality of leadership, communication, and the work environment—are also of decisive importance.

Based on this analysis, it can be posited that engagement can be systematically fostered through targeted interventions. These notably include the establishment of a supportive work culture, the active promotion of participation, the recognition of performance, the provision of opportunities for growth, and access to professional supervision.

These findings correspond with theoretical models that define engagement as the interplay between an employee's personal commitment and the support system an organisation provides. Simultaneously, it confirms that high engagement is not only desirable for employees themselves but also constitutes a strategic factor influencing the quality and effectiveness of healthcare.

Conclusion

Based on theoretical knowledge and an analysis of selected empirical studies, it can be concluded that the work engagement of healthcare personnel represents a multidimensional phenomenom. This phenomenon arises from the intricate interplay of individual predispositions and the characteristics of the work environment. The presented studies consistently confirm that engagement is significantly influenced by the quality of leadership, opportunities for participation in decision-making, perceived support, and personnel resilience to stress. The highlights the imperative for management within healthcare organisations to adopt a strategic approach to engagement. Such an approach necessitates the implementation of programmes designed to foster resilience, enhance communication, bolster teamwork, and adequately recognise the contributions of employees. These interventions hold considerable potential for significantly reducing burnout and concurrently increasing motivation and satisfaction among healthcare staff. Given the paramount importance of workforce sustainability in healthcare, it is therefore essential not only to quantify levels of engagement but also to actively address its determinants as an integral component of modern human resource management.

Neuroscience in Leadership: An Integrative Framework for Optimizing Human Capital Performance

***Kefah-Rakiaa* Dabur**[1,*] **and *Sławomir* Banaszak**[2]

[1] Gaia College, Faculty of Education, Jerusalem, Israel
[2] Adam Mickiewicz University, Faculty of Education, Poznan, Poland

Abstract

Research background: Contemporary organizational science increasingly recognizes the interconnectedness between relational leadership experiences and neurobiological performance optimization, representing a paradigm shift from traditional management models emphasizing individual competency or structural influences.
Purpose of the article: This study proposes an integrated framework for understanding optimal human capital performance by synthesizing findings from organizational psychology, neuroscience, and management theory domains examining manager-employee relationship dynamics, executive presence impacts, and adaptive organizational theory applications.
Methods: A systematic integrative analysis approach was employed to examine convergent themes across three complementary research domains through thematic convergence analysis, theoretical framework mapping, empirical evidence synthesis, and practical application integration following established protocols for business research integration.
Findings & Value added: Analysis reveals four major convergent themes: relationship quality emerges as the primary determinant of performance outcomes across innovation, engagement, and strategic execution domains; neurobiological mechanisms demonstrate consistency through amygdala-medial prefrontal cortex networks sensitive to leadership quality; state-dependent performance occurs through optimal "performance states" created by leadership interactions; and environmental design supports performance through organizational incubation concepts. The integrated framework demonstrates that emotional intelligence, secure organizational attachment, and adaptive environmental responsiveness operate through interconnected neurobiological, behavioral, and cultural mechanisms, with performance optimization occurring within relationship-based organizational environments where relational quality serves as a primary determinant of innovation, engagement, and strategic outcomes.

Keywords: Relationship-based leadership, Executive presence, Adaptive organizational theory, Human capital optimization, Neurobiological management, Organizational attachment

JEL classification: A10, J24

1. Introduction

Contemporary organizational science increasingly recognizes the profound interconnectedness between relational leadership experiences and neurobiological performance optimization (Siegel, 2020). This recognition represents a significant paradigm shift from earlier management models that emphasized either individual competency development or structural organizational influence as primary drivers of business performance. Recent research convergence across organizational psychology, neuroscience, and management theory suggests that human capital optimization operates through complex, dynamic systems where relationship quality fundamentally shapes biological and psychological performance outcomes (Davidson & McEwen, 2012). This understanding challenges traditional dichotomous thinking about

[*] Corresponding author: kefah0112@walla.com

technical versus soft skills, instead proposing sophisticated models of leader-employee interaction that acknowledge the biological embedding of relational management experiences.

The present synthesis integrates three distinct but complementary research domains to propose a comprehensive understanding of optimal organizational performance. The first domain examines relationship-based management in professional settings, specifically exploring how manager-employee relationships influence innovation, engagement, and strategic execution (Dabur, 2025). This research tradition, rooted in organizational attachment theory and leadership psychology, provides empirical evidence for the transformative power of high-quality relational experiences in business contexts. The second domain investigates executive presence impacts on organizational performance through the lens of adaptive organizational theory, examining neurobiological mechanisms underlying leader-team interactions (Kefah & Fuchs, 2025). This research integrates contemporary neuroscience findings with organizational psychology to understand how executive presence creates specific biological conditions that either optimize or inhibit performance outcomes. The third domain presents a comprehensive theoretical framework for understanding organizational development as occurring within "adaptive reality" contexts that emphasize flexibility, connection, and conscious leadership practices (Fuchs, 2025).

The theoretical integration proposed herein addresses a critical gap in contemporary management science by providing a unifying framework that bridges individual performance optimization with broader organizational effectiveness. Current management theories often remain compartmentalized within disciplinary boundaries, limiting their practical application and strategic coherence (Bronfenbrenner, 1977). This synthesis offers a more comprehensive perspective that acknowledges the multidimensional nature of human capital performance while maintaining scientific rigor and business relevance.

2. Methods

This synthesis employed a systematic integrative analysis approach designed to examine convergent themes, complementary findings, and theoretical integration opportunities across three primary research domains. The methodological framework followed established protocols for business research integration while adapting to the specific challenges of bridging diverse disciplinary perspectives and research methodologies (Torraco, 2005).

The data integration process began with thematic convergence analysis, involving systematic identification of overlapping themes and concepts across the three studies. This analysis required careful attention to empirical findings that support similar conclusions through different methodological approaches, ensuring that apparent convergences reflect genuine theoretical and empirical alignment rather than superficial similarities. The thematic analysis examined both explicit convergences, where studies directly address similar phenomena, and implicit convergences, where different studies provide complementary perspectives on related performance processes (Braun & Clarke, 2006).

Theoretical framework mapping constituted the second major methodological component, examining how different theoretical perspectives complement and extend each other while identifying areas of convergence and potential integration. This analysis required careful examination of underlying assumptions, explanatory mechanisms, and scope conditions for different theoretical approaches. The mapping process identified points of theoretical tension or contradiction alongside areas of convergence, ensuring that the integration acknowledges complexity and nuance rather than artificially forcing theoretical coherence (Jabareen, 2009).

Empirical evidence synthesis involved integration of research findings across studies to identify robust patterns and relationships that emerge consistently across different organizational contexts. This synthesis required careful attention to methodological differences across studies while identifying findings that demonstrate consistency despite varying research approaches (Whittemore & Knafl, 2005). The empirical synthesis examined both direct replications, where similar findings emerge from similar methodologies, and conceptual replications, where similar conclusions emerge from different methodological approaches.

Practical application integration analyzed how findings from different studies can be combined to inform more comprehensive approaches to organizational performance optimization and leadership intervention. This analysis examined both individual study implications and emergent implications that arise from theoretical integration. The practical integration considered implementation challenges and opportunities while maintaining grounding in empirical evidence and theoretical coherence (Gough et al., 2012).

3. Results

3.1 Convergent Theoretical Foundations

The synthesis reveals three converging theoretical perspectives that collectively illuminate organizational performance processes in ways that individual approaches cannot achieve independently. These convergent foundations represent a sophisticated integration of established leadership theories with contemporary scientific understanding of neurobiological and behavioral mechanisms (Champagne & Curley, 2009).

Attachment-based leadership theory provides the foundational substrate for understanding how relational management experiences create templates for lifelong performance patterns. Bowlby's (2008) seminal work on attachment security, when applied to organizational contexts, establishes theoretical groundwork for comprehending how secure professional relationships create optimal conditions for performance. This theoretical foundation extends beyond simple emotional support to encompass cognitive performance, strategic competence, and organizational resilience. Contemporary organizational attachment research demonstrates that secure manager-employee relationships facilitate optimal brain function through multiple mechanisms, including stress regulation, neuroplasticity enhancement, and the establishment of healthy neurobiological performance patterns (Ainsworth, 1989). The attachment framework proves particularly valuable in understanding how professional relational experiences become biologically embedded through epigenetic mechanisms and neural pathway optimization.

3.2 Core Convergent Themes

The analysis reveals four major convergent themes that emerge consistently across the three research domains, providing robust empirical and theoretical support for an integrated understanding of organizational performance as fundamentally relational and neurobiologically embedded.

Relationship quality emerges as the primary determinant of performance outcomes across all three studies, with evidence spanning innovation, engagement, and strategic execution domains. The manager-employee relationship research demonstrates how emotional intelligence and supportive leadership significantly influence team performance, resilience, and competitive success through multiple pathways (Dabur, 2025). Leaders who provide consistent emotional validation create organizational environments where employees feel secure enough to take strategic risks, explore innovative possibilities, and develop authentic professional expression. The research reveals that this leadership support operates not simply through encouragement but through sophisticated processes of attunement, responsiveness, and co-regulation that help employees develop internal capacities for emotional regulation and strategic engagement (Hamre & Pianta, 2001).

Neurobiological mechanisms underlying leadership effects demonstrate remarkable consistency across research domains. The amygdala-medial prefrontal cortex network emerges as particularly sensitive to leadership quality, with direct implications for emotional regulation, strategic cognition, and performance function (Callaghan & Tottenham, 2016). Positive leadership experiences enhance the development of this crucial neural network while adverse experiences can disrupt its optimal functioning. The research reveals that leadership quality influences neural performance through multiple pathways, including stress hormone regulation, neurotransmitter balance, and synaptic plasticity enhancement.

State-dependent performance mechanisms reveal how performance outcomes depend on the creation of optimal "performance states" through leadership interactions. These states involve sophisticated integration of neurobiological, psychological, and organizational factors that create conditions either conducive to or inhibitive of optimal performance (Kefah & Fuchs, 2025). Parasympathetic activation emerges as a crucial component, as quality leadership promotes nervous system states that support learning, innovation, and adaptation (Porges, 2011). This activation facilitates enhanced neuroplasticity, enabling the brain to adapt and perform more effectively in response to business challenges and strategic opportunities.

Environmental design for performance emerges as a crucial theme across all studies, with emphasis on creating organizational environments that support optimal performance states. The "organizational incubation" concept provides a sophisticated framework for understanding how physical and relational environments can be designed to support continued performance optimization (Fuchs, 2025). This concept suggests that optimal environments maintain the nurturing, protective qualities of focused development while gradually introducing appropriate challenges that promote growth and strategic adaptation.

3.3 Integrated Performance Optimization Model

The synthesis suggests a comprehensive integrated model where optimal performance occurs through dynamic interaction of multiple interconnected organizational systems operating across different levels of analysis. This model transcends traditional approaches that focus on individual factors or simple cause-effect relationships, instead proposing a sophisticated understanding of performance as emerging from complex organizational system dynamics (Capra & Luisi, 2014).

At the individual level, the model encompasses neurobiological optimization, emotional regulation capacity, and cognitive function as interconnected aspects of personal performance. Neurobiological optimization includes brain architecture enhancement, neural network optimization, and physiological regulation system maturation (Shonkoff et al., 2009). The relational level incorporates leadership attachment security, emotional intelligence quality, and responsive management as fundamental components of performance context. Leadership attachment security provides the foundational trust and psychological safety necessary for innovation and strategic risk-taking (Bowlby, 2008).

4. Discussion

4.1 Theoretical Implications

The synthesis reveals several significant theoretical implications that advance understanding of organizational performance while challenging existing paradigms and assumptions within management science.

The integration transcends traditional individual-organizational dichotomies by demonstrating how leadership experiences directly influence genetic expression and neurobiological performance through sophisticated epigenetic mechanisms (Moore, 2015). This finding supports more nuanced models of leader-employee interaction that acknowledge the dynamic, bidirectional influences between biological and environmental factors. Rather than viewing individual capabilities as fixed determinants of performance outcomes, the research supports understanding individual factors as providing potentials that are activated or suppressed through leadership experiences.

The research collectively supports understanding performance as fundamentally co-regulatory, occurring through dynamic interactions between performing individuals and their leadership environments rather than through autonomous individual processes (Tronick, 2007). This co-regulatory perspective challenges traditional performance models that emphasize individual achievement and self-sufficiency as primary business goals. Instead, the research suggests that optimal performance involves learning to engage effectively in co-regulatory relationships that support mutual growth and strategic adaptation.

While supporting the importance of leadership experiences in establishing performance foundations, the findings suggest greater neuroplasticity throughout careers than traditionally assumed, with significant implications for intervention and support across organizational levels (Doidge, 2007). The research demonstrates that while early career experiences create important performance trajectories, these trajectories can be modified through subsequent high-quality leadership experiences.

4.2 Practical Applications

The integrated framework generates numerous practical applications across leadership development, organizational design, and strategic management domains that address current challenges in supporting optimal human capital performance.

Leadership development implications emphasize prioritizing relationship quality in leadership training as a fundamental prerequisite for effective performance management and strategic execution. This prioritization requires moving beyond traditional technical focus to recognize relationship development as a core leadership competency (Ferreira et al., 2021). Training leaders in attachment-informed practices becomes essential for creating organizational environments that support optimal performance states.

Organizational design applications emphasize utilizing attachment-informed organizational structures that recognize the relational foundations of performance optimization and strategic growth. Such approaches prioritize creating organizational relationships that provide corrective relational experiences while addressing specific performance challenges or strategic objectives. Creating organizational environments that promote optimal performance states involves attention to both physical

organizational spaces and relational organizational processes that support innovation and growth (van der Kolk, 2014).

Strategic management considerations emphasize supporting leader-employee relationships through organizational strategy as a fundamental investment in competitive advantage and sustainable performance. Such support includes leadership development policies, team quality standards, and organizational support services that enable leaders to provide high-quality relational experiences (Shonkoff & Phillips, 2000).

4.3 Limitations and Future Research

This synthesis, while comprehensive in its integration of available research, relies primarily on three related studies and would benefit from broader empirical validation across diverse industries and organizational contexts. The research base, while theoretically sophisticated and empirically grounded, represents a limited sample of the broader organizational research literature. Future research should expand the empirical foundation through systematic replication and extension studies that examine the proposed integrated framework across different industries, organizational sizes, and cultural contexts (Henrich et al., 2010).

Conducting longitudinal studies tracking performance outcomes across extended timeframes emerges as a crucial research priority for validating the proposed integrated framework. Such studies would examine how early leadership experiences influence performance trajectories across career development, leadership advancement, and organizational contribution. Longitudinal research would also investigate the persistence and modifiability of performance patterns established through early leadership experiences (Rutter & Maughan, 2002).

Conclusion

This comprehensive synthesis demonstrates remarkable convergence across diverse research domains, providing robust empirical and theoretical support for an integrated understanding of organizational performance as fundamentally relational and neurobiologically embedded. The evidence consistently indicates that optimal performance occurs when employees experience consistent, responsive leadership within environments designed to support growth and strategic contribution across multiple performance domains (Shonkoff & Garner, 2012).

The adaptive organizational theory framework provides a sophisticated unifying conceptual structure for understanding how leadership relationships create the conditions for optimal performance through neurobiological, psychological, and organizational mechanisms that operate in complex, dynamic interaction (Fuchs, 2025). This theoretical integration transcends traditional disciplinary boundaries while maintaining scientific rigor and business relevance.

The integration has significant implications for leadership development practice, suggesting fundamental shifts toward relationship-based approaches that prioritize psychological safety and co-regulatory capacity development alongside strategic achievement. Organizational design implications emphasize the importance of relationship-based optimization approaches that address both individual performance processes and relational capacity building.

Intercultural Communicative Competence Development in the Context of Managerial Foreign Language Education

Lucia **Dančišinová**[1,*]

[1] University of Prešov in Prešov, Department of Intercultural Communication, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: International contacts in business require specific skills among which intercultural communicative competence is of high importance. At present, cultural clashes can be seen in every aspect of social life. As tertiary education of future managers has to react to the current issues in society, intercultural communicative competence (ICC) development is also included in the process. ICC is frequently developed within foreign language courses. Longitudinal needs analysis among the students of the Faculty of Management and Business (FMB), University of Prešov, proved that the students do not fully understand the importance of intercultural training for the future.
Purpose of the article: The purpose of the article is to describe the importance of ICC for managerial education and describe the theories of Byram (1997) and Fantini (2000) as applied in the courses of English for Specific Purposes taught at the FMB.
Methods: A literature review was used to select two dominant theories of ICC development. Byram´s (1997) and Fantini´s (2000) models were described and applied in the qualitative analysis of the Learning Outcomes entry in the Course Description of Professional English Language for Master´s Degree to illustrate the reality of foreign language teaching of future managers enrolled in English for Specific Purposes (ESP) courses at the Faculty of Management and Business.
Findings & Value added: The results of the literature analysis and its application in the reality of teaching the courses of ESP at the Faculty of Management and Business showed that ICC teaching of future managers is dominantly focused on the target language proficiency aspect. It has further educational implications.

Keywords: Intercultural communicative competence, Culture, Managerial education, English for Specific Purposes, Managerial skills

JEL classification: M14, M53

1. Introduction

Intercultural communicative competence (ICC) is undeniably the ultimate goal of English language learning. As Byram (1997) claims language does not inherently contain cultural aspects, that is why a native speaker ideal should be replaced by an intercultural speaker. This belief is also reflected in the Common European Framework of Reference for Languages (Council of Europe, 2020). The CEFR is based on a sociocultural approach to foreign language learning and teaching and emphasizes the importance of intercultural competence as one of the key objectives of foreign language education (Martin, Nakayama & Carbaugh, 2012, p. 22). The current edition of CEFR „seeks to protect linguistic and cultural diversity, promote plurilingual and intercultural education, reinforce the right to quality education for all, and enhance intercultural dialogue, social inclusion and democracy (Council of Europe, 2025).

Martin and Nakayama (2022, p. 111-112) describe the relationship between communication and culture as „complex“ as „culture influences communication and is enacted and reinforced through communication". It is also the context that is important in communication:

[*] Corresponding author: lucia.dancisinova@unipo.sk

„It is the physical (or virtual) and social setting in which communication occurs or the larger political, social, and historical environment. Power is pervasive and plays an enormous, although sometimes hidden, role in intercultural interactions."

That is why intercultural communication mastery is also part of the business world. It is necessary for the students of economics and management to be trained in intercultural encounters.

ICC is developed also within the language courses as foreign language proficiency is an integral part of it (Fantini, 2000). Wiseman (2002, p. 208) defines ICC as involving „the knowledge, motivation, and skills to interact effectively and appropriately with members of different cultures." It is not only about being able to communicate but also about being appropriate in the context of intercultural situations. That is why it is not enough to know the vocabulary and the grammar rules of any foreign language, it is also necessary to understand what is polite, what are the taboo topics, and other aspects connected with culture. In business relations, it is also necessary to be able to negotiate effectively and appropriately and ICC can help it.

Tertiary education of future managers has to react to the current trends in business. ICC development is part of the training process. Longitudinal needs analysis among the students of the Faculty of Management and Business (FMB), University of Prešov, proved that the students do not fully understand the importance of intercultural training for future. The purpose of the article is to describe the importance of ICC for managerial education and describe the theories of Byram (1997) and Fantini (2000) as applied in the courses of English for Specific Purposes taught at the FMB.

2. Methods

Literature review and analysis of two dominant theories and approaches to ICC are applied in the context of foreign language teaching of future managers enrolled in English for Specific Purposes (ESP) courses at the Faculty of Management and Business as reflected in Course Descriptions to describe the reality of teaching and to highlight the possible problematic areas. As Randolph (2009) states, the literature review is useful in synthesizing different perspectives across disciplines to clarify conceptual frameworks. This method is particularly appropriate for interdisciplinary and methodologically heterogeneous research areas, such as intercultural communication. The selected literature was analysed using thematic coding to identify the most frequently cited and analyzed sources. Two primary sources of available text for literature review were selected as widely used for social networking and available to a wide scholarly audience: Academia and ResearchGate. The review was focused on the depth of analysis over exhaustive breadth.

Peng et al. (2020, p. 58) claim, based on their systematic literature review of intercultural competence research, that the most cited authors in the field are Michael Byram, Darla Deardorff, Claire Kramsch, Mitchell Hammer and Milton Bennett. The literature review of ICC models used in the context of English Language Teaching (ELT) and its assessment undertaken for this study showed that among the most cited are Michael Byram and Alvino E. Fantini.

A qualitative content analysis was then employed to examine the learning outcomes of a foreign language course through the theoretical lenses of intercultural communicative competence. The analysis was informed by two models selected by the literature review. The course description and learning outcomes were systematically coded and interpreted against the criteria established by both models. This dual-theoretical approach enabled a comprehensive evaluation of how the curriculum addresses ICC development in professional and educational contexts.

3. Results and Implications

Two dominant ICC theories were selected by a literature review to illustrate and give background to foreign language teaching at the Faculty of Management and Business. Byram (1997) and Fantini (2000) represent ICC researchers and practitioners who created models aimed at ICC development also within language courses.

3.1 Intercultural Communicative Competence: Byram´s and Fantini´s models

There still has not been agreement on the definition of ICC (Fantini, 2019; Jiang et al., 2022). It can be connected with the conceptualization differences, different academic backgrounds of researchers, or the context of its application. As Wiseman (2002, p. 211) says, ICC is not an innate or accidentally

occurring characteristic but rather a set of conditions that lead to being an interculturally effective communicator. As Byram (1997, p. 7) claims:

> „The concept 'communicative competence' was developed in the anglophone world by Hymes' critique of Chomsky and in the germanophone literature by Habermas. Hymes argued that linguists wishing to understand first language acquisition, need to pay attention to the way in which not only grammatical competence but also the ability to use language appropriately is acquired."

This approach put focus on sociolinguistic competence which led to communicative language teaching (Byram, 1997, p. 8). In the next decades, as Byram (1997) writes, there was a move from a sociolinguistic towards sociocultural competence which also resulted in the CEFR of 1996. Byram (1997, p. 11) points out that despite sociocultural focus, the learners of foreign languages tended to be viewed as „an incomplete native speaker." At present, the updated version of CEFR (2020) is even more focused on linguistic and cultural diversity and intercultural education.

Byram´s (1997, p. 57) model of ICC includes linguistic, sociolinguistic, discourse and intercultural components and involves factors, such as knowledge, skills, attitudes and critical cultural awareness. In a more detailed way, the teaching of foreign languages should focus on the following five factors:

- „knowledge of self and other; of interaction: individual and societal (savoir être)".
- „skills": „interpret and relate (savoir comprendre)"
- „education": „political education critical cultural awareness (savoir s'engager)";
- „skills": „discover and/or interact (savoir apprendre/faire)";
- „attitudes": „relativising self", „valuing other (savoir être)".

ICC components can be understood as „objectives," (Byram, 1997, p. 50-57). Attitudes are aimed at willingness and readiness to seek out, experience, and engage in intercultural settings, while being curious, open and ready to „suspend disbelief about other cultures and belief about one´s own" (Byram, 1997, p. 50). Knowledge aims at being aware of „the general processes of societal and individual interaction" (Byram, 1997, p. 51) and involves learning about one´s own and the other´s countries, their relationships, products and practices. Skills aim at the abilities of interpreting and relating and of discovery and interaction (Byram, 1997, p. 52-53). Education is aimed at critical cultural awareness and identification, evaluation, mediation, and acceptance where necessary based on one´s knowledge, skills and attitudes (Byram, 1997, p. 53).

Byram (1997, p. 70) points out that the model of ICC is designed for educational context and aims at intercultural speaker. He also distinguishes between intercultural competence (IC) and ICC (Byram, 1997, p. 70-71):

> In the first case, individuals have the ability to interact in their own language with people from another country and culture, drawing upon their knowledge about intercultural communication, their attitudes of interest in otherness and their skills in interpreting, relating and discovering, i.e. of overcoming cultural difference and enjoying intercultural contact." ... „On the other hand, someone with Intercultural Communicative Competence is able to interact with people from another country and culture in a foreign language." ... „Their knowledge of another culture is linked to their language competence through their ability to use language appropriately sociolinguistic and discourse competence and their awareness of the specific meanings, values and connotations of the language."

The main difference then lies in the foreign language mastery and proficiency. It supports the idea of ICC development being connected with foreign language teaching and learning.

Fantini (2000, p. 27) believes that ICC development involves language as well as intercultural areas. He points out that most of the ICC researchers leave out the language competence development while language teachers do not include intercultural abilities development in their teaching approach, „despite wide acknowledgement that language and culture are dimensions of each other, interrelated and inseparable" (Fantini, 2000, p. 27). Fantini (2000, p. 27) believes that language not only reflects but also affects people´s worldviews based on which people perceive and interpret their view of the world.

Fantini (2000, p. 28) points out that ICC manifests itself via behavioural traits or attributes, such as „respect, empathy, flexibility, patience, interest, curiosity, openness, motivation, a sense of humor, tolerance for ambiguity, and a willingness to suspend judgment, among others." Fantini (2000, p. 28) identifies five dimensions of ICC:

- awareness,
- attitudes,
- skills,
- knowledge,
- host tongue proficiency.

Fantini (2000, p. 29) considers awareness different from the rest. It is the basis of effective and appropriate interaction. Attitude is connected with affect, knowledge with cognition and skills with behaviour. Fantini (2000, p. 29-30) stresses that the process of ICC development is not finite but rather a continuous and lifelong activity, which is also highly individual as people can progress differently. It is also interconnected with foreign language proficiency development, as without mastering a host tongue, it excludes an intercultural communicator from an important insight into differences in conceptualizations in foreign languages.

Fantini (2000, p. 30) describes the World Learning program context, in which the four levels of development of ICC level are identified as follows:

- „Level I: Educational Traveler — e.g., participants in short term exchange programs/4-6 weeks.
- Level II: Sojourner — longer cultural immersion, e.g., interns and participants in college semester abroad programs and intercultural internships of long duration, 4-8 months.
- Level III: Professional — staff who work in an intercultural or multicultural context; e.g., School for International Training and World Learning employees, alumni, project staff, EIL national directors.
- Level IV: Intercultural/Multicultural Specialist — individuals involved in training, educating, consulting, and advising international students, overseas directors, and cross-cultural trainers."

Later in his research, Fantini (2019, p. 35) reconceptualized ICC based also on an extensive literature review from the multinational and longitudinal point of view:

> „Whereas ICC is the superordinate term, it has multiple subcomponents. For this reason, the literary search also sought to identify precisely the components and aspects that comprise it. The following components emerged consistently from the survey: (1) various characteristics or attributes, (2) three areas or domains, (3) four dimensions, (4) host language proficiency, and (5) degrees of attainment that evolve through a longitudinal and developmental process."

Concerning characteristics, Fantini (2019, p. 35) distinguishes them from personal traits as being related to social and cultural contexts. The three domains are: „the ability to establish and maintain relationships, the ability to communicate with minimal loss or distortion, and the ability to collaborate in order to accomplish something of mutual interest or need" (Fantini, 2019, p. 36). The four dimensions were previously mentioned: attitudes/affect, skills, knowledge, and awareness. The target language proficiency clearly makes intercultural communication easier. The last component is aimed at the fact that ICC attainment is a continuous process and progress which can be measured, for instance, by the four levels of development mentioned previously (Fantini, 2019, p. 37-38).

3.2 ICC Development within ESP Courses

At present, much attention is paid to ICC development within ELT (Abid & Moalla, 2019; Szkudlarek et al., 2020; Morady Moghaddam & Tirnaz, 2022; Pondelíková, 2022; Liao & Li, 2023; Baker, 2024; D'Orazzi & Marangell 2025). Fantini (2019, p. 39) states that at present, the approaches to foreign language teaching are increasingly communicative and competency-based. English language teaching focuses on cultural aspects and the development of intercultural communicative competence is a significant part of language proficiency (Byram & Wagner, 2018; Harper, 2020; Jiang et al., 2022; Cuartas Álvarez, 2020). However, Jiang et al. (2022) claim that effective communication „requires Intercultural Communicative Competence (ICC), but it is often called a hidden curriculum in ELT because its significance is still not acknowledged." Fantini (2019, p. 40) also argues that languages are still taught without a communicative approach and relevant cultural context and there can be huge differences among institutions or countries. There is a need for redefinition of a foreign language teacher´s role as foreign language proficiency needs time and continuous effort (Fantini, 2019, p. 42).

Byram (1997, p. 43) writes that „much acquisition of Intercultural Communicative Competence is tutored and takes place within an educational setting.“ Byram (1997, p. 71) also points out that the location where ICC is developed is important. He identified three location categories with different teacher´s and learner´s roles and relationships: „classroom, fieldwork and independent learning“ (Byram, 1997, p. 71).

Byram (1997, p. 79-80) argues that planning an ICC development curriculum follows six stages:

- the geo-political context: situational factors;
- the learning context: learning locations;
- the developmental factor: cognitive and affective learner´s development;
- the identification of objectives;
- the ICC threshold: goal of ICC;
- sequence in the curriculum: objectives´ ordering.

In comparison, Fantini (2019, p. 40-44) describes the curriculum design as The Process Approach Framework with seven stages of lesson units development: “from presentation of new material to practice, grammar exploration, transposition or use, sociolinguistic exploration, culture exploration, and, finally, intercultural exploration.” Fantini (2019, p. 42) also claims that although ICC development can occur without the host language knowledge, but it is not of the same quality as it lacks direct experience. When a learner masters the host language, he or she can enter a new world with its own culture. The interaction and participation have a significantly different depth.

3.2.1 ICC Development at the Faculty of Management and Business

At the Faculty of Management and Business, foreign language courses are provided by the Department of Intercultural Communication which is responsible for the curricula design in line with the accredited study programmes´ context. English language courses are designed as ESP courses aimed at the development of foreign language communication skills part of which is intercultural communicative competence. There are differences among the study programmes, but at least two ESP courses are compulsory at the bachelor´s and one at the master´s levels of study. All courses at the University of Prešov are described in the Course Descriptions, which also include Learning Outcomes entry. These are to be found online at the university information system MAIS (Prešovská univerzita v Prešove, 2025a).

This section presents a qualitative analysis of course learning outcomes as described in the Course Description of Professional English Language for Master´s Degree. This course was selected as compulsory and attended by the students who had already been enrolled in bachelor´s degree intercultural management courses. The learning outcomes are aimed at equipping students with B2-level language proficiency in accordance with the CEFR (Council of Europe, 2020). The analysis draws on two models of ICC development, which were selected by the literature review: Byram's (1997) and Fantini´s (2000) models.

Attitudes such as openness, curiosity, and a willingness to engage with cultural otherness are partially addressed in the course. The stated competence to “work responsibly in a team on the assigned task of developing the learner's language skills and communicating with team members regardless of cultural diversity” (Prešovská univerzita v Prešove, 2025b) suggests a foundational orientation toward intercultural sensitivity. In terms of knowledge, the course emphasizes the acquisition of domain-specific vocabulary and procedures within the field of management through the target language. The ability to “search for, process and analyze professional information from foreign language sources” (Prešovská univerzita v Prešove, 2025b) opens pathways to cultural exposure, yet the outcomes lack an explicit reference to the cultural contexts of professional communication practices. As such, there is limited indication that learners will develop substantive cultural knowledge about the target language community, which is essential for nuanced and contextually appropriate communication.

The skills component is addressed more directly. The ability to “negotiate and argue in a foreign language” and “work in diverse teams” (Prešovská univerzita v Prešove, 2025b) implies some development of interactive competence. Furthermore, the inclusion of self-regulated learning and reflective practices – “critically evaluate their progress in the study of the relevant foreign language” Prešovská univerzita v Prešove, 2025b) – supports the development of meta-cognitive awareness, a key enabler of ICC. However, the outcomes do not explicitly reference the skills of interpreting cultural meaning or mediating across cultural boundaries, which are central to intercultural communicative acts. Critical cultural awareness, the most evaluative and reflexive component of ICC, is the least developed. While the course encourages

learners to monitor their linguistic progress and explore self-directed strategies for improvement, there is no explicit focus on evaluating cultural perspectives or questioning ethnocentric assumptions. This represents a missed opportunity to incorporate critical pedagogy that would prepare learners not only to use a language proficiently but also to engage with the sociocultural values and discourses embedded within it. Finally, from a linguistic and pragmatic competence perspective, the learning outcomes are relatively robust. Learners are expected to achieve functional proficiency across speaking, reading, writing, and grammar, aligned with CEFR B2 standards. However, there is minimal reference to the pragmatic variation that often characterizes intercultural communication, such as differing norms of politeness, hierarchy, and directness in professional discourse, which can lead to misunderstandings if not explicitly addressed.

Table 1 provides a summary evaluation of the extent to which the analyzed course learning outcomes address key components of intercultural communicative competence (ICC), based on Byram's (1997) framework. Each component is assessed for its presence and depth within the course description.

Table 1. Learning Outcomes Analysis in the Context of ICC Development – Byram´s Model (1997)

ICC Factors (Byram, 1997)	Course Description/ Learning Outcomes	Comments
Attitudes	Moderate	Emphasizes teamwork across cultures, but lacks focus on empathy/perspective.
Knowledge	Basic	Focus on language and content, but not on cultural knowledge explicitly.
Skills	Moderate	Encourages argumentation and teamwork, but lacks explicit cultural skills.
Education/Critical Cultural Awareness	Weak	Reflection is linguistic, not cultural.
Skills/Linguistic/Pragmatic Use	Strong (linguistic), Moderate (pragmatic)	Strong in language skills, pragmatic cultural variation not covered.

Source: Own processing

To sum up, while the course learning outcomes provide a solid foundation for linguistic competence in a professional context, they only partially integrate the components necessary for comprehensive ICC development. To enhance their intercultural dimension, it is recommended that the course explicitly incorporate outcomes related to cultural knowledge, critical cultural reflection, and pragmatic variation across cultures.

Table 2 evaluates the extent to which the course learning outcomes support intercultural communicative competence (ICC) development, based on Fantini's model (2000). Fantini's model emphasizes four core dimensions: Awareness, Attitudes, Skills, and Knowledge, as well as the fifth overarching element—Proficiency in a host language.

Table 2. Learning Outcomes Analysis in the Context of ICC Development – Fantini´s Model (2000)

ICC Dimensions (Fantini, 2000)	Course Description/ Learning Outcomes	Comments
Awareness	Basic	Encourages self-evaluation of language progress, but lacks reflection on cultural assumptions or global perspectives.
Attitudes	Moderate	Promotes cooperation across diverse teams, indicating openness, but does not explicitly address curiosity or empathy.
Skills	Moderate	Focuses on negotiation and teamwork in a foreign language, but lacks focus on cultural interpretation and mediation skills.
Knowledge	Basic	Emphasizes subject-specific vocabulary but does not explicitly address cultural practices or frameworks.
Host Language Proficiency	Strong	B2-level proficiency target and diverse language tasks are well-aligned with functional competence in the second language.

Source: Own processing

Based on Fantini's model of intercultural communicative competence, the course demonstrates strong support for second language proficiency, aligning with CEFR B2 standards. It also moderately addresses attitudes and skills through team-based tasks and negotiation activities, indicating a degree of openness and interactional competence. However, awareness and cultural knowledge are only superficially integrated. Reflection is limited to linguistic progress, and there is no explicit focus on cultural frameworks or interpretive skills. To fully support ICC development as envisioned by Fantini, the course would benefit from incorporating deeper cultural reflection, comparative perspectives, and strategies for mediating intercultural encounters.

Conclusion

The development of Intercultural Communicative Competence (ICC) is a crucial component of foreign language education, particularly in preparing future managers for effective participation in globalized professional environments. This article has demonstrated that while English for Specific Purposes (ESP) courses at the Faculty of Management and Business aim to develop communicative and professional language skills, the integration of ICC, especially its deeper cultural, attitudinal, and critical dimensions, remains underdeveloped.

The article employs a qualitative literature review and content analysis of course learning outcomes through the lens of two theoretical ICC frameworks – Byram's and Fantini's models – to evaluate the current state of intercultural communicative competence development in ESP courses at the Faculty of Management and Business. Byram's (1997) and Fantini's (2000) models offer comprehensive frameworks that highlight the interconnectedness of linguistic proficiency with cultural knowledge, attitudes, and behaviours necessary for meaningful intercultural interaction. The analysis of course learning outcomes through these models reveals that while some elements of ICC, such as teamwork across cultures and language proficiency, are addressed to a moderate or strong extent, others, particularly critical cultural awareness, cultural interpretation skills, and deeper attitudinal engagement, are only partially present or notably absent.

To fully realize the potential of ICC within ESP curricula, it is recommended that course design go beyond linguistic objectives to explicitly incorporate intercultural content, reflective practices on cultural assumptions, and pragmatic competence across cultural contexts. This shift would better align educational practices with the demands of international business environments and contribute to the development of truly intercultural speakers rather than incomplete native speaker models. Ultimately, embracing ICC as an integral goal of language education ensures that graduates are not only linguistically capable but also culturally agile and professionally competent in a diverse world.

Sustainability of Social Service Provision in the Slovak Republic: An Innovative Example of Good Practice

Zuzana **Draková**[1,*]

[1] Trnava University in Trnava, Faculty of Health and Social Work, Department of Social Work, Univerzitné námestie 1, 918 43 Trnava, Slovakia

Abstract

Research background: The Slovak social services system has long been grappling with challenges such as regional disparities, staff shortages, and growing demands for service integration. In the context of an aging population, it is essential to strengthen the sustainability of services through innovative, technology-enabled solutions.
Purpose of the article: The aim of this paper is to analyze the possibilities for strengthening the sustainability of the social services system in the Slovak Republic in the context of demographic challenges. The article aims to present an innovative example of good practice, namely the model of community-oriented assisted living for seniors, and to highlight its potential as an alternative to institutional forms of social care. Based on qualitative research, it demonstrates how such a solution can support personalized, flexible, and cost-effective care that reflects the needs of an aging population while contributing to the systemic sustainability of social services.
Methods: The paper uses a case study supplemented by a qualitative analysis of semi-structured interviews with the founders of the organization and the target group of future users (n = 7). The methodology includes a content analysis of available data.
Findings & Value added: The results suggest that the model presented as an example of good practice, combined with local community support, increases the flexibility, personalization, and accessibility of services. It allows seniors to remain in their natural home environment while maintaining their quality of life. The paper highlights the potential of this innovative model as a tool for the sustainability of social services in the Slovak Republic, which represents an adaptable model linking smart technologies, interdisciplinarity, and volunteering and can serve as a reference framework for the further development of social policies.

Keywords: Sustainability of social services, Community care, Seniors, Slovak Republic, Example of good practice

JEL classification: H50, I10, M10

1. Introduction

The social services system in the Slovak Republic has undergone a transformation in recent decades, driven by demographic, economic, and technological changes. The key challenge today is to ensure its long-term sustainability, including an economic perspective, while respecting the growing needs of social service recipients, especially seniors, as well as public budget constraints and regional differences in the availability and quality of services provided. Schmahl (2022) warns that an even greater care deficit is expected in Slovakia in the coming years. According to Szüdi et al. (2016), faster legislative and financial changes are needed in Slovakia in the area of care for seniors. In this context, Vojtech (2016) adds that it is necessary to create stable and sustainable financial mechanisms that will enable the development of high-quality, accessible, and flexible services.

The sustainability of social service provision in the Slovak Republic is determined by the effective management of available resources, the introduction of innovative financing models, and the application of economically rational management tools that enable the optimization of costs while maintaining the

[*] Corresponding author: zuzana.drakova@truni.sk

quality and accessibility of the care provided. With growing demand for integrated, economically sustainable, personalized, and community-based forms of care, there is also a growing need to implement innovative solutions that reflect not only technological progress but also the principles of interdisciplinary cooperation, participation, and social inclusion, taking into account financial possibilities. Digital transformation, an emphasis on smart solutions, and the development of social entrepreneurship are promising tools for increasing the efficiency, quality, and accessibility of social services in conditions that are increasingly affected by an aging population and an outflow of labor from the social sector. According to the conclusions of a study by Matejovie et al. (2025), insufficient staffing leads to a decline in the quality of care provided. Szweda-Lewandowska (2022) adds that, given the declining workforce in the care and health sectors in many countries, there are already difficulties in fully meeting care needs.

The aim of this paper is to analyze the possibilities for strengthening the sustainability of the social services system in the Slovak Republic in the context of demographic challenges. The paper aims to present an innovative example of good practice, namely the model of community-oriented assisted living for seniors, and to highlight its potential as an alternative to institutional forms of social care. Based on qualitative research, it demonstrates how such a solution can support personalized, flexible, and cost-effective care as a potential framework for the strategic direction of social policies that reflect the needs of an aging population while contributing to the systemic sustainability of social services in Slovakia.

The welfare system in the Slovak Republic works on the principle that individuals must first help themselves. If their situation is so serious that they are unable to help themselves, their family or close friends should help them. If this fails, is lacking, or is unable to completely resolve the individual's unfavorable situation, only then does assistance from the state follow, which is often extremely costly for the state.

Demographic indicators predict an aging population, so it is essential to respond to this situation in an effective manner. In our contribution, we focus on the target group of seniors and consider it important to define who a senior is. Bočáková and Kubíčková (2015) state in their publication that a senior is characterized by belonging to an age group defined as 60 or 65 years of age. According to Matoušek (2008), aging in contemporary Western culture is an age period that begins at 60-65 years of age, when people retire. Some people have a greater need for health care as they age or gradually lose their self-sufficiency. Baňárová et al. (2016) point to the fact that the high increase in functional musculoskeletal disorders in recent decades is also associated with lifestyle changes. Ležovič et al. (2008) argue that it is generally known that with age, the likelihood of health problems and chronic diseases increases, as does the demand for healthcare resources. Individuals need long-term care due to disability, chronic illness, or disease that limits their ability to perform basic self-care or household tasks that must be performed every day. With increasing age, we are therefore talking about an increased need for social and health care. According to Korcová (2025), health and social care should therefore not be seen as isolated sectors, but as two interconnected support tools that together contribute to improving an individual's quality of life.

When moving from their home environment to a facility for seniors, people often have trouble adapting to their new surroundings, roommates, daily routine, etc. If a senior cannot remain completely independent in their own home, we consider community-based assisted living to be a suitable and highly effective alternative. The "Handbook on Community Mental Health Care and Psychosocial Support in Emergencies and Displacement" states that, in the broadest sense of the word, the term community refers to a group of people who share certain characteristics, such as the place where they live or come from, language, interests, beliefs, values, political affiliation, ethnic or cultural identity, sense of belonging, etc. They can be very small, e.g., nuclear family, to extremely large, e.g., the inhabitants of an entire continent. More precisely, communities are social systems characterized by mutual relationships and interactions between their members in a given context. According to Ludvigh-Cintulová and Buzalová (2021), a fundamental problem is the current perception of the transformation of care services for the elderly, which is understood primarily as a shift from institutional to community-based services. The community is thus perceived as a substitute for the state. Responsibility is transferred from the state to the municipal/regional level without the implementation of the necessary financial decentralization and organizational reform. According to Kurucová (2021), the aim of community care for seniors is to maintain their stable functional potential, provide assistance in performing daily activities, maintain the highest possible quality of life, and keep seniors in their original environment for as long as possible.

2. Methods

The paper uses a qualitative research approach to gain a deeper understanding of the potential of an innovative model of assisted living for seniors as a tool for the sustainability of social services in the Slovak Republic. The methodological part was based on a case study of a specific residential project in the village of Hviezdoslavov, which combines elements of assisted living, community support, and smart technologies.

The research focused on the innovative model of community-oriented assisted living Silvers, which was selected as an example of good practice based on the following criteria: focus on independence and quality of life for seniors, offering flexible and personalized services, integrating professional staff into community life, emphasizing the prevention of institutionalization, and supporting seniors to remain in their natural environment.

The data was obtained through:

- semi-structured interviews with deliberately selected representatives of the organization, referred to in the article as P1 and P2, and the target group of future users (n = 7),
- analysis of available documentation and promotional materials such as websites, information brochures, etc.,
- comparative analysis between the assisted living model and the traditional model of facilities for seniors (Table 1).

The interviews were recorded with the participants' consent and subsequently transcribed. The interviews were analyzed by coding thematic categories (e.g., independence, freedom, quality of support, community ties, etc.) using a content analysis approach.

However, our research also has several limitations, including the limited number of participants (n = 7), which reduces the possibility of generalizing the findings, as well as the qualitative nature of the study, which allows for deep understanding but not statistical representativeness, and also the case study of one specific project, which may be influenced, for example, by a specific regional or economic context.

3. Results

The increasing proportion of older people in the population of the Slovak Republic requires the transformation of the social services system towards long-term sustainable, economically stable, flexible and targeted forms of support. One innovative response to this demographic challenge is the introduction of assisted living models that combine senior autonomy with access to personalized support in their natural community environment. In this context, the Silvers assisted living residence is an example of good practice. In the village of Hviezdoslavov, a short distance from the health center and shops, with transport links to Bratislava and the surrounding area, there are 27 modern, low-energy, barrier-free one-, two- and three-room apartments, which can be purchased or rented and furnished and decorated according to the needs and ideas of the senior citizen. The rooms are bright and spacious and offer year-round thermal comfort thanks to ceiling heating and cooling. A great advantage is that the apartments are the homes of their owners – seniors – so they can receive guests whenever they want and also have their own pets (dogs, cats, rabbits, and others). At the Hviezdoslavov residence, seniors can live independently with a wide range of services, animations, and activities throughout the year, because even in old age it is necessary to stay fit, learn, discover, meet people, and build social ties, which is facilitated by a rich and varied program that allows seniors to meet other residents with common interests. Seniors can participate in volunteer activities or discover the local cultural heritage during excursions. The complex has freely accessible common areas that allow seniors to meet other residents and team members. Social events are organized to help create intergenerational bonds and friendships with people from different backgrounds.

Most importantly, seniors have access to attentive, friendly, and professional staff who provide support 24 hours a day, 7 days a week. Seniors are provided with a wide range of services according to their own individual needs to make their daily lives easier, such as cleaning, tele-assistance, laundry, ironing, administrative assistance, as well as hairdressing and other services. The apartments are equipped with fully furnished kitchens where seniors can prepare meals according to their own preferences, but if they want a change or are unable to cook for themselves, they can use restaurant services and partner catering establishments, which prepare varied and balanced meals for them.

In the long term, the construction and operation of facilities for seniors is extremely costly, as compared to assisted living, it requires significant expenditure on staff, heating, lighting, maintenance and repairs to interiors and exteriors, etc. The aim of the following analytical part of the paper is to present the

parameters of the assisted living model in comparison with the traditional institutional model of facilities for seniors in order to highlight the differences between these two models, which are shown in Table 1 below.

Table 1. Comparison of assisted living and facilities for seniors

CATEGORY	ASSISTED LIVING	SENIOR FACILITIES
Self-determination	Seniors are responsible for themselves, and support is organized in such a way that they can do so for as long as they feel able and comfortable.	The facility is responsible for the senior citizen and thus influences a certain degree of their freedom and independence.
Independent living	Seniors live in their own homes and do what they want, when they want.	The senior lives in a social services facility and adapts to the established rules and schedule of the facility.
Supporting independence	Seniors organize their days according to their own needs, while experts are nearby if they need help or support.	Seniors in the facility have a regular daily routine, including wake-up calls, bedtimes, and set meal times. Seniors in the facility become passive recipients of the services provided. For example, even if a senior enjoyed cooking for themselves regularly before entering the facility, they are provided with regular meals at the facility.
Freedom of movement	Seniors can leave their apartments at any time, not only during the day but also at night, depending on their needs.	Seniors may only leave the facility with the knowledge of the operator, who regulates their movement.
Animal companion	You can continue to keep your pet (dog, cat, etc.) with you.	Pets are usually not allowed in senior care facilities due to safety, hygiene, allergies, etc.
Family ties	Seniors can receive visitors at any time, and family members or friends can stay overnight or for the entire weekend.	Visits must comply with the facility's operating rules.
Health	Seniors or their family members are responsible for their health. Support is provided according to their needs or financial possibilities.	The facility is responsible for the health of seniors and coordinates the necessary healthcare.
Meals	Seniors eat according to their own free will. They can cook for themselves or opt for meal delivery, in which case the assistance service will arrange for meals to be delivered.	The facility provides a uniform diet, even if the senior is still able to cook for themselves or would prefer meal delivery.
Privacy	Seniors have their entire apartment at their disposal with complete privacy. If they feel like company, they can find it in the common areas; if they want to be alone, no one will disturb them.	Especially in large social service facilities, people often lose their privacy, sharing a room with a stranger who has their own habits and preferences.
Freedom of life	In senior residences, seniors are not restricted in their movement or in receiving visitors, and they have complete freedom, just as they are accustomed to.	It is difficult to maintain freedom and independence in a care facility. Seniors become part of a system that is unable to reflect their individual needs to the extent they are accustomed to.
Housing	If seniors set up assistance services correctly and their health does not deteriorate radically, they will not have to move anywhere else.	A stay in a senior care facility is often referred to as the "last stop" in a senior's life, because no one else can provide such intensive care.

Source: author's own work based on https://www.silvers.sk/ (2025)

Assisted living represents a significant alternative to traditional social service facilities in terms of long-term sustainability, economic and managerial aspects and efficiency. Compared to institutional care, it is less costly for public budgets and households, as seniors only use the services that meet their current needs. This optimizes costs and eliminates expenditure on redundant or unused services that are provided as part of a package in social service facilities. At the same time, this model significantly contributes to relieving the capacity of social service facilities, which can then focus specifically on clients with a high degree of dependency. In the context of an aging population, it is strategically necessary to shift social care from an institutional model to community-oriented forms of support. Assisted living requires less infrastructure, which contributes to the financial and operational sustainability of the system. At the same time, it allows seniors to maintain their daily activities, freedom of decision-making, and freedom of movement, which has a proven positive impact on their physical and mental health. Conversely, placing a senior in a social services facility is often accompanied by a loss of autonomy, passivity, feelings of isolation, depressive symptoms, and an overall poor adaptation process, which can lead to a deterioration in mental and psychosomatic health. A key aspect of assisted living is its individualization, as services are tailored to the senior's own needs and preferences (e.g., assistance with hygiene, cleaning, meals, etc.), which increases the relevance, effectiveness, and overall quality of life of the individual. Assisted living offers a number of advantages, some of which are mentioned in our article, and is a promising model that combines economic rationality with respect for human dignity, autonomy, quality of life for the aging population, and demographic predictions.

4. Discussion

The discussion section of the paper analyzes the perceptions and experiences of participants, who are representatives of the provider and future residents of assisted living, in the context of current challenges in the field of sustainable care for seniors.

Participants P1 and P2 agreed that it is necessary to address the aging population in Slovakia and provide long-term sustainable services, as aging is a natural part of life. According to Korcová and Borská (2019), aging is a natural process in which time affects human beings. According to authors Nestorová-Dická and Gurová (2022), current and projected geographical differences in population aging and the number of seniors are reflected in the emergence of significant differences in the availability of residential social services in Slovakia from a regional perspective, and this availability is expected to deteriorate further in most Slovak districts. According to Šolcová et al. (2022), Slovakia lags significantly behind in terms of community and home care capacity, as well as in the number of informal caregivers. The introductory part of the discussion points to a consensus among practitioners (P1 and P2) on the need for a systemic solution to demographic ageing, confirming the continuing relevance of this topic outside the academic sphere. The participants' unanimous opinion that aging is a natural, inevitable, and continuously deepening phenomenon corresponds not only with theoretical principles but also with empirical knowledge about demographic trends not only in Slovakia but also in Europe.

All participants from the category of future residents of assisted living (P3, P4, P5, P6 and P7) agreed in their responses that the main and most important factor in their decision to choose assisted living was that they did not want to go to a social services facility because they were afraid of this environment and could not imagine how they would adapt to it. According to Dvořáčková and Mojžíšová (2019), if a senior citizen cannot live safely in their home environment, they must make the difficult decision of whether or not to spend the rest of their life in a residential social services facility. In the new environment, they must adapt to its conditions and find new social contacts. They may be at risk of losing their privacy, experiencing shock from adaptation, and developing "last stop syndrome." Therefore, we see assisted living as a suitable alternative. Participant P1 stated that "in assisted living, seniors begin a new stage of their lives, but they don't have to worry about the new environment because our assistant will introduce them to the other residents, show them around, and be there for them if they have questions or problems finding their way around." Participant P2 added that "since we know that older people have problems adapting, our assistant will go through all the options offered by the community for the self-realization of a particular senior citizen with them so that they can adapt to the new environment as quickly as possible." Sengers and Peine (2021) point to the fact that European trends in age-friendly housing indicate a need to link physical space with community services and social innovations, enabling seniors to remain active and integrated in the long term. This part of the findings points to a high degree of agreement among participants in assessing assisted living as an adequate and preferred alternative to

institutional forms of care. Participants explicitly confirmed the need to maintain autonomy, privacy, and freedom of choice. The participants' responses indicate that the psychological aspect of the decision to choose assisted living and the fear of adaptation difficulties in traditional facilities for seniors are significant factors influencing the choice of care type among older individuals, which provides us with an important empirical contribution to deepening our understanding of seniors' preferences in the area of housing and care.

Participants P3, P5, P6 and P7 agreed that they like the fact that modern technological features are installed in the apartments, which will make them feel safer, because technology is all around us and they see the point of it. According to Draková (2024), we are currently seeing the increasing implementation of modern technologies into everyday life. We are also seeing their gradual establishment in the context of care for the elderly. According to Patyi (2022), dynamic global changes are taking place, mainly related to the unstoppable development of technology. Mangiatordi (2020) adds in this context that modern concepts of housing for seniors increasingly include digital technologies as part of the architectural design, creating environments that promote both independence and safety for residents. Vrančić et al. (2023) state that smart homes empower older adults by increasing their independence and autonomy. According to research by Šimšík et al. (2013) conducted in Slovakia, seniors' self-confidence increased after the installation of technology developed for assisted living in relation to the potential risks of falls or uncertainty. This third thematic line of discussion, which is the implementation of modern technologies, underscores the increasing acceptance of digital elements in the care environment by seniors. Participants positively reflected on their contribution to safety and a sense of control, which is consistent with findings from current research on the concept of smart living.

The discussion showed us that if assisted living is designed in accordance with the principles of personalization, community integration, and technological support, it has great potential to meet the criteria of a sustainable and inclusive model of social services in the Slovak Republic. From an economic and managerial perspective, the assisted living model represents a strategically sustainable innovation in the social services system, which contributes to long-term financial stability and rationalization of public spending through the efficient use of resources, flexible adjustment of services to the individual needs of seniors, and optimization of operating costs.

Conclusion

As mentioned in the article, demographic forecasts indicate that the Slovak Republic will face a significant increase in the elderly population in the coming decades, which will put pressure on the capacity and sustainability of the long-term care system. From the perspective of economics and social services management, it can be said that the long-term sustainability of the system is conditional on the implementation of strategically managed innovations that integrate economic efficiency, transparent financial management, and participatory management approaches, thereby creating the conditions for stability, quality, and adaptability of social services in changing socio-economic conditions. In this context, a shift from institutional provision of social services in social service facilities towards personalized, community-based and technology-supported models is essential. The presented example of good practice in assisted living shows that a combination of independent living, targeted services, social participation, and accessible professional support can fulfill the principles of active and dignified aging. At the same time, however, this model of care is proving to be a cost-effective alternative to classic and traditional social service facilities, not only in terms of public expenditure but also in terms of the individual preferences of recipients, as confirmed by our research. Many research findings also confirm that the flexibility and targeting of assisted living have a positive impact on the quality of life of seniors, reduce the risk of failure in the adaptation process, promote mental and physical activity, and allow for the preservation of elements of individuality, autonomy, and socialization. Community ties, age-friendly design of the environment, and the use of technologies that increase safety, comfort, and a sense of control over one's own life play an important role in this. We can also find inspiration in the form of examples of good practice abroad, e.g. in the Czech Republic, but also in the Netherlands, Austria, and France. In the Czech Republic, the SeniorGarden project offers barrier-free accommodation, a community program, leisure and social activities, modern technologies, teleassistance, volunteering, and more.

The article justifies the choice of assisted living as a tool that adequately responds to the need for flexible, accessible, and economically sustainable support for seniors, especially in areas with low availability of traditional social services facilities. In the long term, assisted living is not only an

innovative but also a systemically desirable element of the transformation of the Slovak social services system, the development of which, however, requires comprehensive support from various sectors and areas, not only financial but also legal, personnel, and strategic integration into national and regional policies in the areas of aging, housing, and social inclusion. Only in this way will it be possible to ensure that care for seniors does not become an unreasonable burden on the system, but rather a natural and dignified part of it.

Organizational Resilience and Employee Well-being: An Evidence-Based Analysis of Workplace Interventions and Performance Outcomes

***Nof* Eilon**[1,*]

[1] Gaia College - Academy of Applied Science & Technology, Faculty of Education, Jerusalem, Israel

Abstract

Research background: Organizations face unprecedented challenges requiring enhanced resilience and workforce well-being to maintain competitive advantage and operational continuity.
Purpose of the article: This study synthesizes current evidence on the relationship between organizational resilience, employee well-being, and performance outcomes through systematic analysis of workplace interventions.
Methods: A systematic review methodology was employed to analyze peer-reviewed literature from Web of Science databases published between 2015-2024, focusing on organizational resilience frameworks, employee well-being interventions, and their measured impacts on business performance.
Findings & Value added: Evidence demonstrates that organizations implementing comprehensive well-being programs and resilience-building interventions achieve significant positive outcomes: business resilience increases (35-25%), reduced absenteeism (10-20%), enhanced stress management capacity, and stronger crisis adaptation capabilities. Meta-analytic findings reveal that employee-level programs produce moderate effects (Cohen's d = 0.15-0.50), while multi-level resilience frameworks that integrate organizational, team, and individual interventions emerge as most effective approaches. Organizations combining mindfulness-based interventions, strategic human resource management practices, and technology-enhanced support systems demonstrate superior performance outcomes and sustained competitive advantage. The synthesis identifies critical success factors including leadership commitment, systematic measurement approaches, and context-appropriate intervention selection. This research contributes novel insights by demonstrating the synergistic relationship between organizational resilience and employee well-being as mutually reinforcing capabilities rather than separate constructs, with practical implications for evidence-based organizational development strategies.

Keywords: Organizational resilience, Employee well-being, Workplace interventions, Business performance, Stress management

JEL classification: J21, J24

1. Introduction

Contemporary organizations function within highly complex and volatile business environments defined by rapid technological advancements, economic instability, global disruptions, and shifting workforce expectations (Williams et al., 2017). The ability to effectively manage disruptions is now a crucial factor for ensuring long-term organizational survival and sustaining competitive advantage. Concurrently, employee well-being has gained prominence as both a moral obligation and a strategic business concern, with increasing evidence demonstrating a strong connection between workforce mental health and organizational performance outcomes (Nielsen et al., 2017).

Organizational resilience involves both absorbing challenges and adapting or transforming to maintain success in adverse conditions (Barasa et al., 2018). This perspective extends beyond traditional recovery models by emphasizing adaptive capacity and ongoing improvement. Recent research demonstrates that organizational and psychological resilience are closely associated with perceived well-

[*] Corresponding author: nofeilon147@gmail.com

being and employee resilience, highlighting the interconnectedness of individual and organizational factors in the workplace (Cooper et al., 2019).

The integration of resilience and well-being research has demonstrated that organizations increasingly recognize the critical role of employees in achieving and sustaining competitive advantage. The "happy worker-productive worker thesis" posits a positive relationship between employee well-being and performance outcomes, though the direction of causality is complex and context-specific (Ogbonnaya et al., 2017). Systematic reviews indicate that human resource management initiatives can improve both employee well-being and organizational performance through diverse HR practices, emphasizing the value of integrated workforce optimization strategies (Nielsen et al., 2017).

The post-pandemic workplace introduces distinct challenges and opportunities for the implementation of integrated resilience and well-being strategies. With 83% of US workers reporting work-related stress (Fidelity & Business Group on Health, 2023) and 33% considering changing employers within the next year, prioritizing workforce well-being is essential for organizational stability and talent retention (Mental Health America, 2024). Workforce expectations have shifted significantly, as 92% of employees value organizations that prioritize emotional and psychological well-being, and 52% regard mental health support as extremely important (American Psychological Association, 2023). Organizations recognized as exemplary workplaces report substantially higher employee well-being scores compared to non-ranked firms, reinforcing the business rationale for comprehensive well-being initiatives (Barton et al., 2024).

2. Methods

2.1 Research Objectives

This study aims to: (1) synthesize current evidence on organizational resilience frameworks and their relationship to business performance; (2) analyze the effectiveness of employee well-being interventions in workplace settings; (3) examine the interconnections between organizational resilience and employee well-being outcomes; (4) identify evidence-based practices for implementing integrated resilience and well-being strategies; and (5) provide recommendations for organizations seeking to enhance both adaptive capacity and workforce optimization.

2.2 Study Design

This study employed a systematic review methodology following established guidelines for management and organizational research (Tranfield et al., 2003). The approach integrates evidence from multiple databases to provide comprehensive analysis of organizational resilience and employee well-being interventions in workplace contexts.

2.3 Search Strategy

Systematic searches were conducted in Web of Science Core Collection, PubMed, and other peer-reviewed databases for articles published between 2015-2024. Search terms included combinations of "organizational resilience," "employee well-being," "workplace interventions," "business performance," "stress management," and "organizational psychology." Boolean operators and truncation symbols were applied to capture all relevant variations of key terms.

2.4 Inclusion Criteria

Studies were included if they: (1) focused on organizational resilience or employee well-being interventions in workplace settings; (2) reported quantitative or qualitative outcome measures related to business performance; (3) were published in peer-reviewed journals indexed in Web of Science; (4) employed rigorous methodological approaches including randomized controlled trials, quasi-experimental designs, or systematic reviews; and (5) provided sufficient detail for analysis of intervention components and outcomes.

2.5 Analysis Framework

Guided by the Adversity-Decision-Outcome (ADO) framework, the analysis examined adverse events, multilevel antecedents, decisions on actions along the resilience process, and outcomes (Williams et al., 2017). This approach enables systematic examination of how organizations develop resilience capabilities and implement well-being interventions to achieve desired performance outcomes.

3. Results

3.1 Organizational Resilience Frameworks

Multi-level Resilience Models

Recent bibliometric analysis of organizational resilience research reveals significant growth, with 622 journal articles from the Web of Science core database examining the field at macro, meso, and micro levels over the past two decades (Hillmann & Guenther, 2021). A more recent bibliometric study analyzing 469 articles identified key themes including crisis management, innovation, COVID-19, dynamic capabilities, sustainability, and change management as crucial to understanding organizational resilience (Mhlanga & Dzingirai, 2024). Current evidence supports multi-dimensional models that address individual, team, organizational, and network-level factors contributing to resilience capabilities.

Contemporary resilience research has advanced beyond viewing resilience as merely "bouncing back" to prior states. An ecology-based reconceptualization categorizes resilience attributes under three dimensions: process, structure, and strategic action, providing a more comprehensive framework for understanding organizational adaptation (Khan et al., 2024). This integrated perspective recognizes that resilience manifests in multiple forms depending on adversity severity: avoidance, absorption, elasticity (static resilience), and learning and rejuvenation (dynamic resilience) (You, 2023). Organizations must attend to the need to challenge predetermined beliefs, assumptions, and behaviors, developing new workarounds through cultivating collaborations within and outside organizational boundaries.

Workplace team resilience has been proposed as a potential asset for work teams to maintain performance in the face of adverse events (Hartwig et al., 2020). Research demonstrates that team-level resilience serves as a mediating factor between individual psychological resources and organizational outcomes, with particular importance for complex, high-stakes work environments.

Empirical Crisis Evidence

Recent mixed-methods research examining organizational resilience throughout actual crisis periods provides valuable insights into how resilience functions in practice rather than through retrospective analysis (Hollands et al., 2024). This research highlights that organizations navigate crises through dynamic processes involving preparedness, responsiveness, adaptability, and learning—four pillars that together constitute organizational resilience capacity. The importance of relational connections within and outside organizations provides contextual conditions in which resilience-related resources and capabilities can be activated (You, 2023). Evidence shows that organizations can tap into their networks when responding to adverse events, with resilience functioning as a latent capacity banked in social relationships and organizational ties.

Measurement and Quantification

Addressing previous criticisms that resilience has been conceptually unclear and requiring clearer measurement approaches (Hillmann & Guenther, 2021), recent research has developed operational assessment frameworks. The Organizational Resilience Index (ORI), based on the Integrated Resource Efficiency View framework, provides quantifiable measures for four levers of organizational resilience, enabling managers to assess and benchmark their organizations' resilience capabilities (Vishwakarma et al., 2023). This capability-based conceptualization decomposes resilience into three successive stages—anticipation, coping, and adaptation—each with underlying capabilities that together form organizational resilience (Duchek, 2020; Raetze et al., 2022).

Strategic Human Resource Management and Resilience

Strategic human resource management (SHRM) practices play a transformative role in enhancing organizational resilience. Empirical research using structural equation modeling with 501 employees demonstrates direct effects of SHRM practices on organizational resilience, with organizational culture serving as a crucial mediating factor (Elsayed & Di Nardo, 2024). This evidence validates and extends earlier theoretical work on developing organizational resilience capacity through strategic HRM (Lengnick-Hall et al., 2011), providing contemporary empirical support for integrated HR and resilience strategies.

Contextual Considerations

While much resilience research focuses on large organizations, recent umbrella reviews examining small and medium-sized enterprises reveal important contextual factors. SME resilience is constrained by

three key barriers: firm size limitations, financial constraints, and ineffective leadership, while organizational culture and information systems emerge as critical enablers (Koporcic et al., 2025). These findings highlight that resilience-building strategies must be tailored to organizational context, resources, and capabilities.

Dynamic Capabilities and Adaptation

Organizations must develop their capacity for change, which is predicated on the capacity for continuous learning (Lengnick-Hall et al., 2011). Evidence indicates that resilient organizations demonstrate superior learning agility, enabling rapid adaptation to changing market conditions and operational challenges. Knowledge, as the key antecedent of organizational resilience, is fundamental for resilient system performance across diverse organizational contexts (Barasa et al., 2018).

3.2 Employee Well-being Interventions

Mindfulness-Based Approaches

Meta-analytic evidence from randomized controlled trials demonstrates that mindfulness-based interventions produce small to moderate positive effects on well-being outcomes immediately post-intervention, with sustained benefits observed at follow-up periods for healthcare professionals and other occupational groups (Vonderlin et al., 2020). These interventions consistently improve stress management capacity and emotional regulation among participants.

Systematic analysis of workplace health promotion initiatives targeting stress reduction, mental health, cardiometabolic health, health-related behaviours, and musculoskeletal disorders reveals that mindfulness interventions demonstrate superior effectiveness compared to control conditions (Richardson & Rothstein, 2008).

Organizational Support Systems

Meta-analytic evidence indicates that interventions specifically found to be useful include enhancing employee control, promoting physical activity, cognitive behaviour therapy for stress management, and problem-focused return to work programmes (Richardson & Rothstein, 2008). Evidence supports multi-component approaches that address both individual skill development and organizational environmental factors.

Research demonstrates that organizational interventions directly targeting working conditions and environments, including flexible working arrangements and frameworks to deal with violence and harassment at work, produce superior effectiveness compared to individual-focused approaches alone (Nielsen et al., 2017).

Technology-Enhanced Interventions

Systematic review evidence indicates low-to-moderate quality support for individual-focused digital interventions in supporting employee well-being and managing work-related stress through web-based platforms (Richardson & Rothstein, 2008). Digital interventions offer scalability and accessibility advantages, though effectiveness varies based on intervention design and participant engagement levels.

3.3 Performance Outcomes

Business Performance Indicators

Empirical research demonstrates that work environment has positive influence on employee performance and psychological wellbeing, with significant relationships between employee psychological wellbeing and performance (Cooper et al., 2019). Organizations implementing comprehensive well-being programs report measurable improvements in productivity metrics, quality indicators, and financial performance measures.

Meta-analytic evidence demonstrates that employee well-being and resilience are factors that directly influence personnel performance. Recent research further demonstrates that work events influence engagement through emotional responses, with this relationship strengthened by psychological capital resources (Penza & Gasiorowska, 2023), with particular importance in high-stress occupational contexts (Ogbonnaya et al., 2017). Organizations investing in well-being initiatives observe reduced turnover rates, lower healthcare costs, and enhanced organizational reputation.

Crisis Adaptation Capabilities

Research indicates that organizations providing employees with more resources to deal with the stress of uncertainty, with organizational resilience serving as an external resource, demonstrate superior crisis response capabilities (Cooper et al., 2019). Evidence shows that organizations with established resilience frameworks demonstrate superior crisis response capabilities and faster recovery times during disruptive events.

Systematic review findings indicate the importance of building organizational resilience across various contexts, including external threats such as economic and financial crises, natural disasters, the COVID-19 pandemic, cybersecurity issues, and military conflicts (Barasa et al., 2018). Organizations with integrated resilience strategies show enhanced capacity to navigate multiple simultaneous challenges.

4. Discussion

4.1 Integrated Resilience-Wellbeing Model

The evidence supports an integrated model where organizational resilience and employee well-being function as mutually reinforcing capabilities rather than separate organizational domains (Williams et al., 2017). Recent organizational resilience research demonstrates that adverse events and antecedents at individual, group, organizational, and network levels affect organizational-resilience processes and their outcomes.

This integration addresses previous criticisms of resilience research, where researchers have criticized resilience for being conceptually unclear, requiring clearer conceptual development and measurement approaches (Hillmann & Guenther, 2021). By linking resilience capabilities to well-being outcomes, organizations can develop more precise metrics and intervention strategies.

4.2 Implementation Strategies

Multi-Level Intervention Design

Organisational intervention studies that target work conditions and create a preventative or primary approach to reducing occupational stress are more effective in promoting healthier workplaces than individual-focused approaches (Nielsen et al., 2017). Effective implementation requires addressing individual skill development, team dynamics, organizational policies, and environmental factors simultaneously.

The job stress prevention process involves three distinct steps: problem identification, intervention, and evaluation, requiring organizations to be adequately prepared with management commitment and employee involvement (Richardson & Rothstein, 2008). Successful programs demonstrate sustained engagement through participatory approaches and continuous improvement processes.

Evidence-Based Practice Selection

Meta-analytic evidence indicates that several workplace interventions are effective in improving work ability, well-being, perceived general health, work performance, and job satisfaction while reducing psychosocial stressors, burnout, and sickness absence among healthcare workers (Vonderlin et al., 2020). However, organizations must carefully select interventions based on their specific contexts, workforce characteristics, and organizational readiness.

The evidence suggests that no single intervention can work in isolation, requiring a package of interventions at organization level which could be accessed by those in need (Barasa et al., 2018). Successful organizations adopt portfolio approaches that combine individual, team, and organizational-level interventions.

Measurement and Evaluation

Employee well-being research requires systematic examination of diverse factors shaping the relationship between employee well-being and organizational outcomes through integrated frameworks of antecedents, mediators, moderators, and outcomes (Ogbonnaya et al., 2017). Organizations implementing resilience and well-being initiatives must establish comprehensive measurement systems to track progress and optimize interventions.

Employee perceptions are usually the most sensitive measure of stressful working conditions and often provide the first indication of intervention effectiveness (Richardson & Rothstein, 2008). Evaluation

frameworks should incorporate both subjective well-being measures and objective performance indicators to provide comprehensive assessment capabilities.

Limitations and Future Directions

Current research demonstrates several limitations requiring attention in future studies. Understanding the resilience dynamics during organizational change is particularly important given challenges including technological disruption, economic uncertainty, and social transformation (Williams et al., 2017). Organizations must adapt resilience strategies to address emerging technological and social challenges.

Additionally, cross-cultural validation of resilience and well-being interventions requires basic epidemiological studies to understand context-specific factors and implementation barriers (Barasa et al., 2018). Global expansion of evidence-based practices requires cultural adaptation and context-specific validation.

Conclusion

Our paper shows that organizational resilience and employee well-being are closely interconnected capabilities. Together, they provide measurable competitive advantages by enhancing adaptability, reducing operational risks, and improving human capital performance. We emphasize that organizations implementing integrated approaches achieve superior outcomes compared to those addressing resilience or well-being in isolation (Nielsen et al., 2017).

Evidence-based interventions including mindfulness training, organizational support systems, and multi-level resilience frameworks consistently demonstrate effectiveness across diverse organizational contexts (Vonderlin et al., 2020). However, successful implementation requires systematic approaches that address individual, team, organizational, and environmental factors simultaneously.

Organizations seeking to optimize both resilience and well-being should prioritize: (1) comprehensive assessment of current capabilities and needs; (2) multi-level intervention design addressing individual skills and organizational systems; (3) evidence-based practice selection tailored to specific organizational contexts; (4) robust measurement and evaluation frameworks; and (5) continuous improvement processes based on employee feedback and performance outcomes (Richardson & Rothstein, 2008).

Future research should focus on developing more precise measurement frameworks, exploring cultural and contextual moderators of intervention effectiveness, and examining long-term sustainability of integrated resilience-wellbeing strategies (Hillmann & Guenther, 2021). As organizations face increasingly complex challenges, the integration of resilience and well-being capabilities will become essential for sustainable competitive advantage and workforce optimization.

Abstract

Research background: In the field of commerce, there is a need to explore the factors that influence decision-making processes and strategic management. However, limited research has focused specifically on the Slovak business environment, warranting further investigation.
Purpose of the article: The article examines the relationships between primary area of operation (production, services, combination) and company size concerning aspects of implementation and control of strategies in a select group of companies in Slovakia. It aims to highlight the importance of the commercial strategic management issue.
Methods: Using the VOSviewer software, a bibliographic analysis of Scopus articles on the given issue was performed to lay the foundation for the examination of the issue. To analyze the research data, statistical methods were employed, including the nonparametric Kruskal-Wallis test and post hoc analysis using the pairwise comparison post hoc test. These tests were applied to identify statistically significant differences between the chosen factors and individual variables relating to commercial strategic management.
Findings & Value added: The findings indicate that the company size significantly influences commerce strategic decisions in areas such as Efficiency and Perfection, Quality and Deliberation, Formality and Collaboration, and Alignment and Stability. Similarly, the company size seems to play a role in strategic management and Efficiency and Perfection, Quality and Deliberation, Formality and Collaboration, and Alignment and Stability decisions. The findings offer insights into the specific context of commerce strategic management in the Slovak business environment. They also provide practical implications for decision-making processes, resource allocation strategies, and organizational design. The research fills a gap in the literature by focusing on the relationships between various business factors and adds a new point of view using bibliographic analysis in this field. It also serves as a foundation for future research, guiding further exploration and understanding of the factors affecting commerce strategic management in Slovakia.

Keywords: Commerce, Strategy, Management, Business, Sustainability

1. Introduction

In the ever-evolving field of commerce, the need to comprehend the intricate factors shaping decision-making processes and strategic management has been a recurring theme in academic discourse.

* Corresponding author: skypalova.renata@gmail.com

While numerous studies have explored these dimensions, there exists a noticeable void in the literature, particularly in the context of the Slovakian business environment. The scarcity of research in this specific domain emphasizes the urgency for a more nuanced investigation. The current article addresses this research gap by focusing on the relationships between the primary area of operation (production, services, combination) and company size concerning the implementation and control of strategies within a selected group of companies in Slovakia. The endeavor is motivated by the recognition of the critical importance of the commercial strategic management problem in this unique context.

To establish a comprehensive understanding and direction for this inquiry, the researchers undertook a meticulous bibliographic analysis using Voswiever, a systematic approach for reviewing and analyzing Scopus articles relevant to the issues at hand. This methodological choice laid a robust foundation for the study, ensuring that the research direction aligns with the existing scholarly discourse. In the subsequent stages, the researchers employed rigorous statistical methods to analyze the collected data. The nonparametric Kruskal–Wallis test and post hoc analysis, specifically the pairwise comparison post hoc test, were applied. These analytical tools were instrumental in identifying statistically significant differences between chosen factors and individual variables related to commercial strategic management. The findings of the study illuminate several critical insights. Notably, company size emerges as a significant influencer of commerce strategic decisions, impacting areas such as Efficiency and Perfection, Quality and Deliberation, Formality and Collaboration, as well as Alignment and Stability. Similarly, the primary area of operation was found to exert a significant influence on commercial strategic management, particularly in the identified aspects. The study significantly contributes to the existing body of knowledge by providing insights specific to the context of strategic management in the Slovakian business environment. The utilization of statistical analysis methods enhances the rigor of the findings, adding a layer of credibility to the research outcomes. Beyond its academic contributions, the study holds practical implications for decision-making processes, resource allocation strategies, and organizational design within the commercial sector. By addressing a specific gap in the literature, the research adds a novel perspective to the understanding of the relationships between factors influencing commerce strategic management. In conclusion, this study not only sheds light on the dynamics of commerce strategic management in Slovakia but also acts as a foundation for future research in the field. The insights generated pave the way for further exploration and a deeper understanding of the intricate factors that shape and influence commerce strategic management in the unique business landscape of Slovakia.

2. Literature review

Strategic management in the realm of commerce plays a pivotal role in shaping the direction and success of businesses. The globalized and dynamic nature of the business environment necessitates a thorough understanding of the factors influencing decision-making processes and the formulation of effective strategies (Afsharian et al., 2021). While strategic management principles are widely studied, it is crucial to contextualize these theories within the specific dynamics of Slovak business. This literature review aims to explore the importance of strategic management in commerce, particularly in the Slovakian context, and to delve into the examination of relationships between primary areas of operation and company size are concerning strategy implementation and control. Strategic management encompasses the formulation and execution of initiatives that align organizational goals with the ever-changing business environment accroding to Amdam and Benito, (2022). In the context of commerce, Amin and Viganola (2023) state that, where competitiveness and adaptability are paramount, effective strategic management is instrumental for sustained growth and survival. A comprehensive review of the literature reveals that strategic management contributes to enhanced decision-making, resource optimization, and the establishment of a sustainable competitive advantage. In Slovakia, a country with a burgeoning business landscape and unique socio-economic factors, the significance of strategic management is heightened. BadewI (2016), underscores the importance of tailoring global strategic frameworks to fit the local context, considering factors such as cultural nuances, regulatory environments, and market dynamics specific to Slovakia.

Studying strategy implementation and control is of paramount importance as it represents the critical juncture where organizational aspirations move from conceptualization to realization. While strategy formulation sets the direction and goals, effective implementation ensures that these strategies are translated into actions and embedded into the daily operations of the organization Bahoo et al. (2020). This phase serves as the linchpin connecting strategic planning with tangible outcomes. Understanding

strategy implementation is essential for aligning resources, managing change, and fostering organizational agility. Moreover, according to Bena (2017), the study of strategy control is indispensable for evaluating whether the executed strategies are achieving their intended results and making necessary adjustments. In essence Banerjee et al., (2023) states that, delving into strategy implementation and control is a strategic imperative, ensuring that organizations not only set ambitious goals but also possess the capability to bring these visions to fruition and adapt them as circumstances evolve.

The identification of a research gap in the realm of strategic management in commerce, particularly focusing on the nuanced areas of implementation and control with considerations for factors such as company size and primary areas of operations (production, services, combination), holds paramount significance within the academic and business landscape (Ben-Daya et al., 2019; Cachón-rodríguez et al., 2022; Safrankova & Sikyr, 2024).

This gap signifies an untapped opportunity for scholars to delve into the intricacies of strategic decision-making processes, shedding light on the unique challenges and dynamics that emerge in varied organizational sizes and operational domains. By undertaking this exploration, researchers can contribute substantively to the refinement and evolution of existing strategic management theories, advancing the field and offering a more comprehensive understanding of how size and primary operational focus interact in the successful execution and oversight of strategies. Importantly, this scholarly endeavor is not merely an academic pursuit; it carries tangible implications for practitioners, policymakers, and businesses, guiding them towards more effective and tailored strategic approaches. Bridging this gap in the literature is, therefore, not only an intellectual endeavor but also a pragmatic imperative, as it empowers businesses to make informed decisions and optimizations in their strategic management practices, fostering adaptability and resilience in the dynamic landscape of commerce.

2.1 The role of company size and primary area of operation in strategic *commerce*

The role of company size and the primary area of operation in strategic commerce constitutes a complex and multifaceted domain that merits in-depth exploration and scholarly attention. The varying sizes of companies, ranging from small and medium enterprises (SMEs) to large corporations, inherently influence strategic decision-making processes, resource allocation, and overall organizational dynamics (Anini et al., 2015). Likewise, the principal domain of activity, pertaining to production, services, or a mix of the two, presents distinct obstacles and prospects that profoundly influence strategic plans. Not only is it intellectually stimulating to comprehend the complex interactions between these two important variables, but it also has significant applications, particularly for Slovak enterprises. Slovakia's socioeconomic structure, with its fluctuating market conditions and many industry sectors, emphasizes how crucial it is to customize strategic approaches to the unique characteristics of businesses according to their size and operational focus. Surprisingly, there is a significant vacuum in the literature at the moment when it comes to fully covering these particular dynamics in the Slovakian context. As Slovak businesses aim to maintain their competitiveness and growth, they must find ways to bridge this gap (Kormaníková and Šenková, 2023). These strategies must be both effective and flexible enough to respond to the unique issues that arise across various industry sectors and operational scales. Understanding how a company's size and major region of activity connect with strategic decision-making becomes crucial for promoting innovation, resilience, and sustainable business development as Slovakia places itself within the larger European economic landscape. Moreover, this exploration should extend beyond a binary consideration of size and primary focus; other contextual factors, such as regulatory environments, cultural nuances, and technological landscapes, should also be integrated into the analytical framework to provide a holistic understanding of strategic commerce in Slovakia. As researchers delve into this multifaceted subject, they contribute not only to the theoretical foundations of strategic management but also offer invaluable insights that can guide businesses, policymakers, and academics in navigating the intricate landscape of commerce in Slovakia (Ďaďo et al., 2015; Daft and Albers, 2012; Dahmash, 2015).

The role of company size and the primary area of operation in strategic commerce stands as a pivotal yet understudied domain, particularly in the context of Slovak businesses. Recognizing the intricate interplay between these variables is imperative for a comprehensive understanding of strategic decision-making processes according to Maylor and Turner (2017). Slovakia's distinct socio-economic environment, along with its varied business community, calls for a careful investigation of the ways in which a company's size and main industry—production, services, or both—affect the development, execution, and oversight of strategic plans. Given the current dearth of a substantial body of literature

addressing these particular processes in the Slovakian context, this investigation becomes even more crucial. Comprehending the ways in which these variables influence strategic trade in Slovakia has significant practical ramifications in addition to being intellectually stimulating. Tailored strategic methods can help Slovak businesses achieve their goals of growth and competitiveness by utilizing insights into the unique opportunities and difficulties presented by different company sizes and operational foci. Moreover, the absence of literature on this subject underscores the urgency to fill this research gap, offering a foundation for evidence-based decision-making for businesses and policymakers alike. Additionally, it is imperative to broaden the scope of inquiry to consider other relevant factors that might synergistically impact strategic outcomes, thus contributing to a more holistic understanding of the multifaceted nature of strategic commerce in the Slovakian business landscape (Dwivedi et al., 2021; Foley and Manova, 2015; Sikyr et al., 2024).

2.2 Hypothesis

As the literature states, there are many factors that influence the process of strategic management in commerce. However, since this is a very broad field in the field of commerce and management, we decided to examine the very implementation and control of commercial strategies and through the factors of the size of the company and the primary area of operation of the company.

Considering the size of a company as a factor in strategic commerce is crucial also, according to Teece (2018). The scale of a business significantly influences strategic decision-making processes. Larger enterprises, with more resources, often engage in sophisticated planning, while smaller companies may adopt more agile approaches. Understanding the impact of company size is essential, especially in Slovakia's diverse business landscape. Analyzing this factor provides valuable insights for practitioners aiming to optimize strategic management practices in varying business environments.

Analyzing the primary area of operation is vital in strategic commerce, influencing how organizations tailor their strategies. Whether in production, services, or a combination, this factor shapes strategic decisions. Understanding its impact is crucial for adapting strategies to the unique dynamics of each sector (Hou et al., 2022). In Slovakia's diverse business landscape, exploring this influence provides practical insights for businesses seeking strategic alignment with their operational domains.

- Hypothesis 1 (H1): Variations in strategic management practices will be evident among companies of different sizes – small, medium, and large. Specifically, it is anticipated that larger enterprises will exhibit a higher likelihood of employing more extensive and sophisticated strategic management processes compared to their smaller counterparts. This hypothesis posits that the scale of operations and available resources influences the depth and complexity of strategic management efforts.
- Hypothesis 2 (H2): Distinctive differences in strategic management practices will be identified across various primary areas of operation – production, services, and a combination of both. Companies engaged in production are expected to prioritize strategic initiatives related to supply chain efficiency and production optimization, while service-oriented businesses may focus on enhancing customer experiences. This hypothesis anticipates that the nature of the primary area of operation significantly influences the strategic management approaches adopted by businesses in commerce.

3. Methods

This paper evaluates the previously identified aspects of the strategic management process in commerce companies operating in Slovakia. This includes the identification of the strengths and weaknesses of the implementation and control process in specific companies, as well as proposals for rationalization measures to improve their strategic management commerce processes. The research was conducted in the form of interviews and a questionnaire survey. Prior to sending out the questionnaire, pilot verification was carried out with the help of experts on the given subject and representatives from the private sector, with improvements made accordingly. As the presented study is based on previous research, which included a pilot study, pilot verification was considered sufficient. However, interviewers had to be familiar with the topic of interest and the questionnaire itself as part of the preparatory phase. Of the 400 companies addressed, 352 cooperated, representing a response rate of 87.50%. Following data adjustment (Teunissen, 2003), all 350 companies fell into the sample set. For this research, stratified randomization was applied. The respondents were selected based on one criterion – the participating legal entity must be registered in the Slovak Commercial Register. The only additional prerequisite was that a company representative aware of the issues surrounding strategic

management in commerce filled in the questionnaire. This inevitably meant addressing a director or top management levels. For the purpose of this study, two main factors were selected, size of company and primary area of operation either production, service or combination. The first part of the questionnaire contains questions related to the interface / qualifications of the respondents. This is followed by a general part about strategic management and then 5 basic key areas from the mission, vision and goals, through the external environment followed by the internal environment. The penultimate part of the questionnaire contains questions focused on the selection, evaluation and implementation of strategies. The last part consists of questions aimed at checking strategies. A total of 67 questionnaire survey questions are prepared, divided into 7 sections according to the topic. Considering the focus of the publication, the last area of research focused on strategy implementation and control was selected. For each response sought, a Likert scale of 1-5 was applied: 1 – completely disagree; 3 – neutral; 5 – completely agree. To analyze the differences in the application of planning processes, the following research questions were formulated:

RQ1 - Does the implementation and control processes in the company depend on size of company?
RQ2 - Are there differences in the implementation and control processes in companies depending on the primary area of operation?

For the purpose of this study variable optimization was applied for a better understanding of the individual factors (see Table 1 below).

Table 1. Operationalisation of variables

Variable	Operationalisation	Method of measurement
Size of the company	Determinate your company size according to number of employees.	Micro enterprise; small business; medium enterprise; big business
Primary are of operation	Select the primary are of business operations	Production; services; a combination of the above
Implementation and Control questions (Implementation; Quality; Formalization; Alignment; Reserves; Growth; Motivation; Monitoring; Check; Review)	Items G1 - G10	Likert scale 1–5: 5 – completely agree; 3 – neutral; 1 – completely disagree

4. Results

The first goal of the work was to make a basic overview of scopus articles using bibliographic analysis, while the articles should focus on the implementation and control of strategic commercial processes. This analysis offers a basic overview of the main relevant terms, followed by an overview of the number of words, connected to the cluster distribution of the issue using graphic maps showing the classification of clusters and the temporal development of publications. The last step enables the preview of the heat map for the deep field cluster of the graphic representation of the intensity of the relevant terms.

Table 2. Occurence score model

Term	Occurence*
Supply chain	365
Price	329
Condition	289
Production	251
Profit	245
Adoption	227
Interaction	207
Supplier	196
Manufacturer	196

*60% Rellevance score and 10x term article repetition
Source: own processing

The analysis of Scopus articles on strategic management in commerce, utilizing the Voswiever software, reveals a significant emphasis on terms that underscore the intricate dynamics of business operations. The prominence of terms such as "supply chain," "price," "condition," "production," "profit," "adoption," "interaction," "supplier," and "manufacturer" indicates a robust focus on core elements that drive strategic decision-making. The recurring mention of "supply chain" emphasizes the critical role of efficient logistical processes and interconnected networks in commerce. "Price" and "profit" signify a keen interest in financial aspects, underscoring the importance of pricing strategies and profitability in strategic management discussions. The term "condition" suggests an examination of external factors influencing business environments. The frequent occurrence of "production" aligns with a concentration on operational processes and manufacturing strategies. "Adoption" indicates a consideration of innovative practices or technology integration in commerce. The terms "interaction," "supplier," and "manufacturer" collectively highlight the significance of collaborative relationships, supply chain dynamics, and production partnerships. In summary, the prevalence of these terms reflects a comprehensive exploration of multifaceted aspects crucial to strategic management in the complex landscape of commerce.

Table 3. Relevance score model

Term	Relevance
Trading enterprise	6.53
Strategic sustainability	6.12
Post digital world	5.32
Busy executive	4.75
Latest management development	4.67
Practical thinking	4.60
Briefing	4.54
Technology roadmapping	4.20
Virtural water	3.43

Source: own processing

The highest relevance scores in the analysis, particularly for terms such as "Trading enterprise," "Strategic sustainability," "Post digital world," "Busy executive," "Latest management development," "Practical thinking," "Briefing," "Technology roadmapping," and "Virtual water," suggest a nuanced focus on contemporary and forward-looking aspects of strategic management in commerce. The term "Trading enterprise" reflects a specific attention to businesses engaged in trade, potentially indicating an emphasis on global market dynamics and international trade strategies. "Strategic sustainability" suggests a growing awareness of the importance of integrating sustainable practices into strategic management approaches, aligning with the global shift toward environmentally conscious business strategies. The mention of the "Post digital world" indicates a recognition of the evolving digital landscape and its impact on commerce, highlighting the need for adaptive and innovative strategic approaches. "Busy executive" and "Latest management development" point towards a focus on the role and skills of executives, indicating a consideration of leadership and professional development in the context of strategic management. "Practical thinking" may suggest a pragmatic orientation, emphasizing the application of strategic concepts in real-world scenarios. "Briefing" hints at a preference for concise and informative communication, potentially reflecting an awareness of the importance of effective communication in strategic decision-making. "Technology roadmapping" underscores the significance of technology planning and foresight in strategic management, aligning with the rapid advancements in technology that shape modern commerce. Lastly, the term "Virtual water" could indicate an exploration of water footprint considerations, reflecting a broader awareness of sustainability in resource management within the strategic context. Overall, the highest relevance scores for these terms suggest a comprehensive and future-oriented exploration of strategic management in commerce, encompassing technological advancements, sustainability, leadership, and practical application.

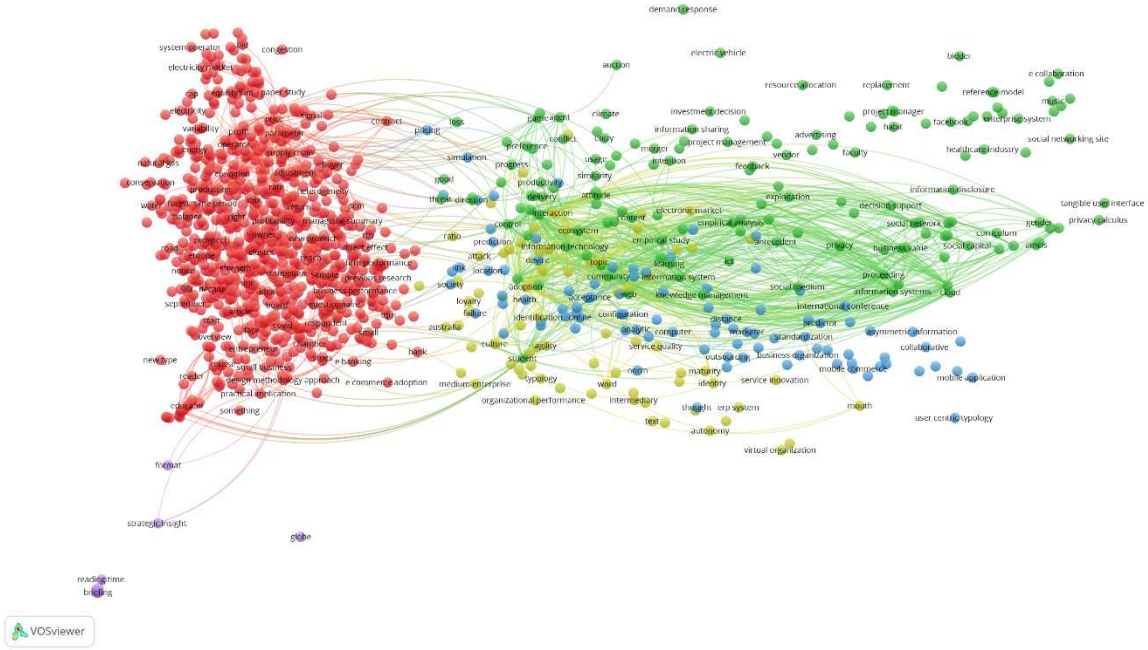

Figure 1. Graphic illustration - Network visualization
Source: own processing

For each of the 2377 terms, a relavance score was calculated. Based on this score, the most relevant terms were selected. The default choice was set for 60% most relevant terms. In total 1426 terms are presented with occurence more then 10 times per article.

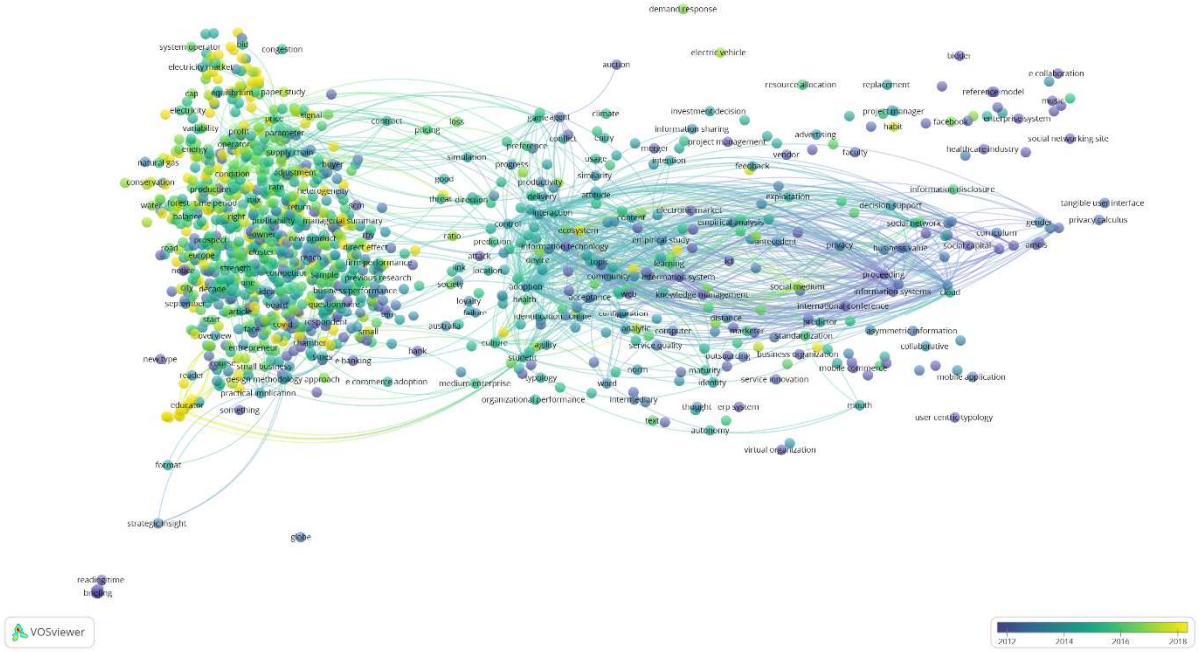

Figure 2. VOSviewer analysis - term relevance
Source: own processing

The examination of Scopus articles utilizing the Voswiever software yields insightful observations concerning the pivotal themes shaping discourse on strategic management within the commercial domain. The prevalence of terminologies such as "supply chain," "price," "condition," "production," "profit," "adoption," "interaction," "supplier," and "manufacturer" accentuates the intricate and multifaceted nature inherent in the processes of strategic decision-making. These terminologies collectively underscore the significance of factors such as logistical efficiency, financial considerations, external influences,

operational methodologies, innovation, and collaborative relationships within the commercial sphere. Transitioning to the metric of relevance scores, expressions like "Trading enterprise," "Strategic sustainability," "Post digital world," "Busy executive," "Latest management development," "Practical thinking," "Briefing," "Technology roadmapping," and "Virtual water" elucidate a prospective orientation within strategic management discourse. "Trading enterprise" implies a focus on global market dynamics, while "Strategic sustainability" signifies a dedication to incorporating sustainable practices into strategic paradigms. The reference to the "Post digital world" indicates cognizance of the transformative impact of the evolving digital landscape on commerce, necessitating adaptive strategic approaches. "Busy executive" and "Latest management development" signal an attention to executive roles and competencies, emphasizing considerations related to leadership and professional growth. The term "Practical thinking" suggests a pragmatic inclination, emphasizing the application of strategic concepts in real-world scenarios. "Briefing" underscores the importance of succinct communication in the context of strategic decision-making. "Technology roadmapping" aligns with the significance attributed to technology planning, while "Virtual water" denotes an awareness of water footprint and sustainability considerations in resource management within the strategic context. These relevance scores collectively underscore a comprehensive and forward-looking exploration of strategic management within commerce, encompassing aspects of technological advancements, sustainability practices, leadership dynamics, and practical application.

4.1 Strategic management area - implementation and control of strategy

Strategy implementation and control, often referred to as strategic management, is a critical process for organizations seeking to realize their long-term goals. From careful planning and resource allocation to monitoring and adaptation, this process involves systematic steps to ensure the effective execution of strategic initiatives. Key aspects are regular evaluations, the use of KPIs to track progress and create feedback to ensure that the strategies implemented are in line with the original objectives. In addition, it is essential to manage risks and be ready to adapt to changes in the internal and external environment. Communication and obtaining feedback from employees and stakeholders are key elements that support the success of this process. Strategy implementation and control are not static tasks, but a dynamic cycle of continuous improvement and adaptation for an organization to achieve and maintain its competitive advantage. In our research, we therefore focused on several specific points mentioned above. Questions G1 to G10 examine the given issue.

4.2 Implementation and control of the strategy according to the size of the company

The implementation and control of the strategy according to the size of the enterprise is adapted to the specific needs and characteristics of the organization. In the case of large enterprises, where there is a complex structure and multi-level management, it is crucial to create specialized teams and management layers that will be responsible for individual aspects of the strategy. The use of technological tools and software enables effective monitoring and coordination of all phases of implementation. In addition, it is essential to ensure clear communication channels between different levels of management and operatives. Conversely, SMEs may prefer a more flexible approach with less formal management. In these cases, it may be important to encourage creativity and rapid adaptation to environmental changes. Regardless of business size, it is critical to constantly monitor and evaluate strategy to adapt to dynamic business conditions and achieve long-term success. The following table shows the average values of the company size factor.

Table 4. Report

Size of the company		G1	G2	G3	G4	G5	G6	G7	G8	G9	G10
Microbusiness	Mean	3,38	3,65	3,16	3,46	3,61	3,59	3,71	3,10	3,10	3,14
Small business	Mean	3,66	3,70	3,44	3,69	3,64	3,86	3,80	3,52	3,60	3,53
Medium business	Mean	3,32	3,62	3,41	3,42	3,51	3,77	3,43	3,49	3,51	3,37
Large business	Mean	3,91	3,97	3,68	3,73	3,76	3,96	3,60	3,88	3,75	3,78
Total	Mean	3,59	3,75	3,45	3,58	3,63	3,81	3,62	3,55	3,53	3,49

Source: authors (2025)

Analysis of strategy implementation and control factors shows that large enterprises excel at implementing decisions, probably due to having enough resources for smooth and effective implementation. On the contrary, small and medium-sized enterprises placed more emphasis on the quality of strategy implementation than on its speed. From the point of view of sharing best practices, large enterprises have formal mechanisms ensuring the transfer of best practices between different areas of activity. Synchronizing strategy with organizational structure is a priority for both large and small businesses. As a result, large enterprises generally have the highest values in the area of sufficient reserve resources, signaling their ability to respond to deviations from strategy. Strategic planning shows a high impact on the growth of sales and profits in both large and small businesses. Employee motivation and remuneration are of a high standard, with the highest values for large enterprises. Monitoring and evaluation of implemented strategies is actively practiced primarily in large and small enterprises. Pre-implementation and post-implementation control is gaining importance for both small and large businesses. Overall, it can be concluded that the size of the company plays a key role in the process of strategy implementation and control, influencing the approach of organizations to various aspects of strategic management.

Table 5. Test Statistics[a,b]

	G1	G2	G3	G4	G5	G6	G7	G8	G9	G10

a. Kruskal Wallis Test
b. Grouping Variable: Approximate size of the surveyed company by employees
Source: authors (2025)

The analysis showed that there are significant differences in some aspects of strategy implementation and control between different sizes of enterprises. In the case of implementing decisions (G1) and monitoring and evaluating strategies (G8), the differences are more pronounced between medium-sized and large enterprises, as well as between micro-enterprises and large enterprises. These differences

can be explained by probable differences in available resources and complexity of business processes between different size categories. In the field of quality vs. speed of implementation (G2), the differences are most pronounced between medium and large enterprises, indicating a possible different prioritization of these factors depending on the size of the enterprise. The sharing of best practices (G3) and control before strategy implementation (G9) show differences between micro-enterprises and large enterprises, which may reflect different approaches to management practices and the needs to exchange experiences in these categories. Monitoring after strategy implementation (G10) shows differences between medium-sized and large enterprises, as well as between micro-enterprises and large enterprises, which could be related to the complexity of monitoring and evaluating strategies depending on the size of the organization. These findings could provide valuable information for managers when adapting the company's strategy in an effort to increase the efficiency and success of strategy implementation.

4.3 Implementation and control of the strategy according to the primary area of operation

The implementation and control of strategy can be influenced by the company's primary area of operation, whether it is manufacturing, service provision, or a combination of both. Each of these areas has its own characteristics and specifics that can affect the way an organization formulates, implements and monitors its strategies.

1. Production:
   - In the area of production, the key factor is the efficiency of production processes and supply chain management.
   - Strategies may include optimizing production processes, investing in technology, and securing the supply of raw materials.
   - Control includes product quality monitoring, storage management and optimization of production capacities.
2. Services:
   - In the service industry, a focus on providing high-quality and customized customer service is important.
   - Strategies may include personalized service, process innovation, and building a strong relationship with customers.
   - Control consists in measuring customer satisfaction, monitoring service performance and adapting the strategy according to the changing needs of clients.
3. Combination (Production and services):
   - For organizations combining production and services, a balanced approach to both sectors of activity is a key aspect.
   - Strategies may involve the integration of production and services, resulting in the delivery of value to customers at multiple levels.
   - Control includes monitoring performance in both sectors and ensuring synergy between them.

In any case, it is important that organizations take into account the specific needs and challenges of their primary area of operation when formulating and implementing strategy. For example, a manufacturing business will focus more on processes and inventory optimization, while a service business will emphasize customer interactions and innovative approaches. The combined company will have to manage the challenges of both industries and look for synergistic opportunities. In the following table, we will look at the average values in the case of the factor primary area of operation of the company.

Table 6. Report

Primary are of peration		G1	G2	G3	G4	G5	G6	G7	G8	G9	G10
Production	Mean	3,44	3,81	3,43	3,48	3,67	3,66	3,62	3,67	3,57	3,42
Service	Mean	3,53	3,63	3,38	3,54	3,67	3,81	3,59	3,47	3,45	3,47
Combination	Mean	3,81	3,90	3,60	3,75	3,54	3,95	3,68	3,58	3,64	3,59
Total	Mean	3,59	3,75	3,45	3,58	3,63	3,81	3,62	3,55	3,53	3,49

Source: authors (2025)

The manufacturing, service, and combination sectors differ greatly in terms of strategy implementation and control. Manufacturing businesses lead with lower ratings in the area of decision implementation, indicating greater complexity and the need to overcome technological and logistical obstacles. The ability to execute decisions quickly and efficiently, on the other hand, is a strength of the service sector and can be a hallmark of service delivery. The best values are attained by combined businesses, demonstrating their adaptability and capacity to carry out decisions in both industries. In terms of quality versus speed of implementation, manufacturing and service industries stand out with an emphasis on quality, while combined businesses show a balanced approach. Regarding the sharing of best practices, manufacturing enterprises achieve lower values, while services and combined industries show a higher importance of sharing best practices. The manufacturing sector exhibits greater difficulty in aligning strategy with organizational structure, whereas services demonstrate a superior ability to do so. The highest values are attained by combined businesses, demonstrating a balanced strategy in both industries. The services sector outperforms the industrial sector in terms of allocating appropriate reserve resources. Lower values are obtained by combined firms, which would suggest that reserve resource management requires a balanced strategy. Services outperform manufacturing in terms of how strategic planning affects sales and profit growth, whereas combined businesses have a balanced approach. Employee motivation and compensation are more important in the service industry, while combined businesses show higher value in both aspects. Monitoring and evaluation strategies show similar values for manufacturing and combined industries, with a greater need for improvement for services. A pre-strategy check shows similar values for manufacturing and combined industries with lower values for services. In the area of control after strategy implementation, manufacturing and combined enterprises achieve similar values with lower values for services. Overall, it follows that each industry has its own specific characteristics and prioritizes different aspects of strategy implementation and control.

Table 7. Test Statistics[a,b]

	G1	G2	G3	G4	G5	G6	G7	G8	G9	G10

b. Grouping Variable: Area in which the company primarily operates
Source: authors (2025)

The difference in values between production and combination in question G1 on the implementation of decisions can be interpreted in the context of the characteristics of these industries. Manufacturing enterprises achieve lower values, which could be related to their probably higher complexity and the need to solve logistical and technological challenges in the process of implementing decisions. On the contrary, combined enterprises achieve the highest values, indicating their flexibility and ability to implement decisions in both sectors. These differences may reflect the different needs and challenges associated with strategy implementation in manufacturing and combined activities, where combined firms are likely to excel in adaptability and coordination of decisions for different parts of their business structure.

5. Discussion

The research methodology employed in this study involved a comprehensive evaluation of strategic management processes within commerce companies operating in Slovakia. The focus was on identifying strengths and weaknesses in the implementation and control processes of specific companies and proposing rationalization measures to enhance their strategic management processes. The research utilized a combination of interviews and a questionnaire survey. Prior to the questionnaire distribution, pilot verification was conducted with subject matter experts and private sector representatives to refine the instrument. With a response rate of 87.50%, 350 out of 400 companies formed the final sample after data adjustment. Stratified randomization was applied based on the criterion that participating entities must be registered in the Slovak Commercial Register, with company representatives familiar with

strategic management issues completing the questionnaire. The survey instrument consisted of 67 questions divided into seven sections, focusing on respondent qualifications, general strategic management aspects, and specific key areas ranging from mission and vision to internal and external environmental considerations. The final part of the questionnaire centered on strategy implementation and control, with Likert scale responses ranging from 1 (completely disagree) to 5 (completely agree). The subsequent analysis of Scopus articles, employing Voswiever software, provided valuable insights into the dominant themes in strategic management within commerce. Such an aprroach using Voswiever software is also recommended by Arruda et al. (2022) . The identification of terms such as "supply chain," "price," "condition," "production," "profit," "adoption," "interaction," "supplier," and "manufacturer" underscored the multifaceted dynamics influencing strategic decision-making. Simmiliar studies such as Purnomo et al. (2021) came to familiar conclusions in Indonesia. A relevance score analysis revealed contemporary and forward-looking focuses, with terms like "Trading enterprise," "Strategic sustainability," "Post digital world," and others indicating a nuanced exploration of strategic management aspects which are supported also by Rao and Shukla (2023). Further visualizations and heat maps illustrated the intensity and relevance of identified terms, offering a comprehensive overview of the research landscape. Ellegaard, O. (2018) on the other hand, he warns that bibliographic methods should be used wisely, as their misinterpretation can lead to errors.The subsequent survey results delved into the implementation and control of strategic processes, focusing on size and primary area of operation as variables. The statistical analyses, including Kruskal-Wallis tests, unveiled significant differences in various aspects of strategy implementation and control based on the size and primary area of operation of companies. Regarding company size, large enterprises demonstrated superior decision implementation and monitoring of strategies, likely due to enhanced resources, especially after Covid pandemic. This aprroach is highlighted also by Ketchen et al. (2020). Small and medium-sized enterprises emphasized the quality of strategy implementation over speed, and large enterprises exhibited formal mechanisms for sharing best practices and aligning strategy with organizational structure. For example Arora et al. (2018) points out the problematic of decline of science in corporate R&D. Strategic planning's impact on sales and profit growth, employee motivation, and strategy monitoring were actively practiced in both large and small enterprises. Bryson et al. (2018) states that strategic planning in any company is essential. Concerning the primary area of operation, manufacturing enterprises prioritized decision quality over speed, while service industries excelled in implementing decisions quickly. The need to focus in such a factors is also pointed by Jones andKierzkowski (2018). Combined enterprises exhibited a balanced approach. This aprroach is also supported by Pawlak and Kołodziejczak (2020) in agriculture sector. Significant variations were observed in sharing best practices, aligning strategy with organizational structure, and allocating sufficient reserve resources among different sectors. In conclusion, the research provides a robust methodological approach, integrating Scopus articles analysis with survey data to offer comprehensive insights into the strategic management processes of commerce companies in Slovakia. The findings shed light on the impact of company size and primary area of operation on specific aspects of strategy implementation and control, offering valuable information for managers seeking to enhance efficiency and success in strategic management. The study contributes to the broader discourse on strategic management in the complex landscape of commerce, emphasizing the need for adaptable and nuanced approaches tailored to specific organizational contexts. Such a research can contribute to better understanding of business enviroment and can be compared to other countries such as Czech Republic or Poland, where simmiliar results emerge accroding to Šebestová (2020).

Conclusion

In conclusion, this study provides a significant contribution to the understanding of strategic management within the context of commerce in Slovakia. Through meticulous research methodology and robust analysis, the study investigates the interplay between company size, primary area of operation, and the implementation and control of strategies. The findings shed light on various dimensions of strategic management, including Efficiency and Perfection, Quality and Deliberation, Formality and Collaboration, as well as Alignment and Stability. The research fills a notable gap in the literature by focusing specifically on the Slovakian business environment, emphasizing the importance and timeliness of its findings. By addressing this gap, the study not only enhances theoretical understanding but also offers practical implications for decision-making processes, resource allocation strategies, and organizational design within the commercial sector. The utilization of statistical analysis methods adds rigor to the

findings, bolstering their credibility and applicability. The comprehensive exploration of factors influencing commerce strategic management in Slovakia lays the groundwork for future research endeavors in this field, guiding further exploration and understanding of the multifaceted dynamics at play. The hypotheses formulated and tested in this study provide valuable insights into the variations in strategic management practices among companies of different sizes and primary areas of operation. Through rigorous methodology and meticulous data analysis, the study illuminates the nuanced challenges and opportunities inherent in strategic decision-making processes within the Slovakian business landscape. Looking ahead, this research sets the stage for continued exploration and refinement of strategic management practices in commerce, particularly within Slovakia's unique context. By bridging the gap in the literature and offering a nuanced understanding of the factors shaping commerce strategic management, this study facilitates evidence-based decision-making and strategic optimization in the dynamic and evolving landscape of commerce within Slovakia. On the other hand, however, we want to point out the limitations of this work in the context of the sample size, which although represents the representation of Slovak companies, but a larger number of respondents would help. We also see limitations as a result of focusing only on Slovak companies, even if the results were compared with similar works in the discussion, there is still an overview of, for example, the Central European region as a whole. Therefore, we still see possibilities for deeper research.

Optimizing Managerial Decision-Making Processes in Complex Organizational Systems using Transformative Intelligence-Based Strategic Frameworks

***Hila* Fuchs**[1,*]

[1] Gaia College - Academy of Applied Science & Technology, Faculty of Education, Jerusalem, Israel

Abstract

Research background: Complex organizational systems present significant challenges for managerial decision-making, often characterized by cognitive biases, competing pressures, and multidimensional dynamics between cognitive, emotional, and social management processes.
Purpose of the article: This research examines how Transformative Intelligence (TI) theory can enhance leaders' decision-making processes and strategic action implementation within complex organizational systems, with focus on understanding relationships between cognitive flexibility, psychological adaptability, and managerial effectiveness.
Methods: A mixed-methods approach was employed including quantitative analysis of data from 60 committee chairs and 87 committee members, plus qualitative systematic content analysis of 50 committee minutes from 2019-2023. Selection and characterization committees in special education served as the case study context, representing complex managerial decision-making systems with ethical dilemmas, budget constraints, and competing organizational pressures.
Findings & Value added: Analysis revealed systematic cognitive biases operating across leadership levels: representativeness heuristics (73.2% of cases), availability heuristics (79.3%), and anchoring heuristics (81.7%). Chairpersons with high levels of transformative intelligence (17.3% of sample) showed significant improvements in decision quality metrics: bias identification and reduction (89.2% vs. 34.7% in control group), decision flexibility (78.4% vs. 23.8%), and innovative solution development (84.1% vs. 19.2%). Psychological flexibility demonstrated high correlations (r = 0.66-0.79) with all transformative intelligence components.

Keywords: Decision Making Processes Management, Transformative Intelligence, Complex Organizational Systems, Cognitive Biases, Psychological Flexibility

JEL classification: J24, J21

1. Introduction

Complex organizational systems present unprecedented challenges for managerial decision-making in contemporary business environments. These systems are characterized by multiple stakeholders, competing objectives, resource constraints, and ethical considerations that create cognitive load and decision-making complexity beyond traditional management frameworks (Fasolo et al., 2025). Research demonstrates that cognitive biases significantly impact strategic decision-making processes, with systematic biases operating similarly across individuals including overconfidence, escalation of commitment, and various heuristic-based errors that can substantially impair organizational performance (Laureiro-Martínez & Brusoni, 2018).

Research demonstrates that cognitive biases significantly impact strategic decision-making processes, with systematic biases operating similarly across individuals including overconfidence, escalation of commitment, and various heuristic-based errors that can substantially impair organizational performance (Laureiro-Martínez & Brusoni, 2018). Recent comprehensive reviews reveal that while the detrimental influence of cognitive biases on organizational performance is well-established, there remains insufficient

[*] Corresponding author: hila.ariel@gmail.com

attention to bias mitigation interventions that can improve organizational decisions in practice (Fasolo et al., 2025).

The emergence of cognitive flexibility as a critical factor in organizational adaptation has garnered significant attention in management research. Cognitive flexibility, defined as the ability to match the type of cognitive processing with the type of problem at hand, enables decision makers to achieve significantly higher decision-making performance when facing complex organizational challenges (Laureiro-Martínez & Brusoni, 2018). This capability proves particularly crucial in uncertain environments where traditional decision-making frameworks may prove inadequate.

Psychological flexibility has emerged as another vital component in organizational effectiveness, representing the ability to adapt to changing circumstances, manage emotions effectively, and stay aligned with personal and organizational values (Archer et al., 2024). Research indicates that psychological flexibility serves as a mediating mechanism for various organizational outcomes, including stress resilience, job performance, and adaptive capacity in complex work environments.

The intersection of cognitive biases, psychological flexibility, and organizational decision-making creates a complex landscape requiring sophisticated theoretical frameworks to understand and optimize managerial effectiveness. Current research reveals that decision-making in organizational contexts is influenced by both internal factors such as perception and external factors including digitalization and environmental complexity (Castaldi et al., 2021). However, existing frameworks often fail to integrate these multiple dimensions into coherent approaches for managerial practice.

This research addresses these gaps by examining how Transformative Intelligence theory can enhance decision-making processes in complex organizational systems. The study focuses on selection and characterization committees in special education as a representative case of complex managerial environments characterized by ethical considerations, resource constraints, and multiple stakeholder interests requiring sophisticated decision-making capabilities.

2. Methods

2.1 Research Design

This study employed a mixed-methods approach designed to examine the relationship between transformative intelligence components and decision-making effectiveness in complex organizational contexts. The research design integrated quantitative analysis of decision-making patterns and qualitative content analysis of decision processes to provide comprehensive understanding of managerial effectiveness factors.

2.2 Participants and Setting

The study examined selection and characterization committees in special education systems, representing complex organizational environments with multiple stakeholders, ethical considerations, and resource constraints. The sample included 60 committee chairs and 87 committee members across various organizational levels and functional areas.

Selection criteria required participants to have at least two years of experience in committee leadership or membership roles, involvement in decision-making processes with significant organizational impact, and willingness to participate in both quantitative assessments and qualitative interviews. The special education context was selected due to its representation of complex decision-making environments involving ethical dilemmas, budget constraints, legal requirements, and multiple stakeholder interests.

2.3 Data Collection

Quantitative data collection involved comprehensive assessment of cognitive bias patterns, psychological flexibility measures, and decision-making effectiveness indicators. Participants completed validated instruments measuring representativeness heuristics, availability heuristics, anchoring biases, and other cognitive biases documented in organizational decision-making research (Kahneman & Tversky, 1974).

Psychological flexibility was assessed using established measures examining acceptance, mindfulness, values clarification, and behavioral adaptation capabilities (Hayes et al., 2006). Decision-making effectiveness was evaluated through multiple indicators including bias recognition, decision revision capability, innovative solution generation, and stakeholder consideration in decision processes.

Qualitative data collection involved systematic content analysis of 50 committee meeting minutes from 2019-2023, providing longitudinal perspective on decision-making patterns and processes. Content analysis focused on identifying decision-making strategies, bias manifestations, flexibility demonstrations, and innovative problem-solving approaches across different organizational contexts and challenges.

2.4 Analytical Approach

Quantitative analysis employed correlation analysis, regression modeling, and group comparison techniques to examine relationships between transformative intelligence components, psychological flexibility, and decision-making effectiveness measures. Statistical analyses were conducted using established procedures for organizational research, with appropriate controls for organizational level, experience, and contextual factors.

Qualitative analysis followed systematic content analysis procedures, involving independent coding by multiple researchers, inter-rater reliability assessment, and thematic identification across decision-making episodes (Kuo et al., 2018). Integration of quantitative and qualitative findings provided comprehensive understanding of mechanisms underlying effective decision-making in complex organizational systems.

3. Results

3.1 Cognitive Bias Patterns in Organizational Decision-Making

Analysis revealed systematic patterns of cognitive biases operating across multiple levels of organizational leadership, consistent with previous research on professional decision-making (Montibeller & von Winterfeldt, 2015) and recent comprehensive reviews of bias mitigation in organizational contexts (Fasolo et al., 2025). Representativeness heuristics appeared in 73.2% of cases, typically manifesting as over-reliance on stereotypical characteristics when evaluating individuals or situations rather than considering base rate information or statistical evidence.

Availability heuristics occurred in 79.3% of cases, demonstrating tendency to overweight easily recalled information or recent events when making probability assessments or strategic evaluations. This bias proved particularly problematic in resource allocation decisions where memorable but unrepresentative cases influenced funding priorities and program development strategies.

Anchoring heuristics appeared in 81.7% of cases, showing strong tendency to rely heavily on initial information presented during decision-making processes. Committee chairs frequently anchored on first proposals or initial budget figures, with insufficient adjustment based on subsequent information or changing circumstances.

These bias patterns created systematic deviations from optimal decision-making processes, leading to suboptimal resource allocation, inadequate consideration of alternative solutions, and reduced adaptability to changing organizational requirements. The combination of multiple biases operating simultaneously created compound effects that significantly impaired decision quality across organizational levels, consistent with recent frameworks identifying the need for systematic bias mitigation interventions in organizational settings (Fasolo et al., 2025).

3.2 Transformative Intelligence Components and Decision-Making Effectiveness

Chairpersons identified as having high levels of transformative intelligence (17.3% of the sample) demonstrated significant improvements across all decision-making effectiveness metrics compared to control groups. This high-performance group showed superior bias identification and reduction capabilities (89.2% vs. 34.7% in control group), indicating enhanced metacognitive awareness of their own decision-making processes.

Decision flexibility measures revealed substantial differences between high and low transformative intelligence groups (78.4% vs. 23.8%), demonstrating enhanced ability to modify initial decisions when presented with new information or changing circumstances. This flexibility proved crucial for adaptive management in complex organizational environments requiring responsiveness to stakeholder needs and environmental changes, aligning with recent research on organizational flexibility and performance outcomes (Eng et al., 2025).

Innovative solution development showed the largest effect sizes (84.1% vs. 19.2%), indicating that transformative intelligence components particularly enhance creative problem-solving capabilities. High-

performing leaders demonstrated ability to generate novel approaches to organizational challenges while maintaining practical feasibility and stakeholder acceptance.

Perceptual flexibility emerged as a key component, representing metacognitive ability to recognize and change meaning contexts when interpreting organizational challenges and opportunities. Leaders with high perceptual flexibility showed enhanced ability to reframe problems, consider multiple perspectives, and identify underlying assumptions affecting decision-making processes.

3.3 Psychological Flexibility as Mediating Mechanism

Psychological flexibility demonstrated high correlations with all components of transformative intelligence ($r = 0.66$-0.79), suggesting integrated relationships between acceptance-based psychological processes and cognitive adaptability in organizational contexts (Archer et al., 2024). These correlations remained significant after controlling for experience, organizational level, and contextual factors.

The mediating role of psychological flexibility appeared particularly important for stress management during high-stakes decision-making episodes. Leaders with higher psychological flexibility maintained decision-making effectiveness under pressure, showed reduced emotional reactivity to criticism or setbacks, and demonstrated greater persistence in pursuing optimal solutions despite organizational obstacles.

Values-based decision-making emerged as a crucial component, with psychologically flexible leaders showing enhanced ability to maintain ethical standards and stakeholder consideration while pursuing organizational objectives. This capability proved essential for sustainable decision-making in complex environments involving competing interests and limited resources.

3.4 Organizational Meta-Capability Development

When all transformative intelligence components operated synergistically, analysis revealed emergence of organizational meta-capability enabling continuous learning, process optimization, and sustained improvements in decision-making effectiveness. This meta-capability transcended individual leader performance to create systemic improvements in organizational decision-making processes, consistent with recent frameworks for designing intelligent organizations through human-AI collaboration principles (Kolbjørnsrud, 2024).

Organizations with multiple high-transformative intelligence leaders demonstrated enhanced collective decision-making capabilities, including improved information sharing, reduced groupthink tendencies, and enhanced consideration of diverse perspectives in strategic planning processes. These organizational-level effects suggested potential for systematic cultivation of transformative intelligence across management hierarchies.

4. Discussion

4.1 Theoretical Implications for Management Science

The research reveals significant theoretical implications for understanding decision-making effectiveness in complex organizational systems. The integration of cognitive flexibility, psychological flexibility, and values-based decision-making provides a more comprehensive framework than traditional approaches focusing solely on analytical or technical competencies (Smit et al., 2025).

The finding that psychological flexibility mediates relationships between cognitive capabilities and decision-making effectiveness challenges traditional separation between cognitive and emotional factors in management research. This integration suggests that effective decision-making requires simultaneous development of analytical thinking skills and psychological adaptability, consistent with emerging research on holistic leadership approaches and recent empirical validation of psychological flexibility as a key organizational resource (Archer et al., 2024).

The emergence of organizational meta-capability when multiple leaders demonstrate transformative intelligence suggests potential for systemic interventions addressing decision-making effectiveness at organizational rather than individual levels. This finding extends current research on organizational learning and adaptation by identifying specific mechanisms through which individual capabilities aggregate to create organizational capabilities, aligning with contemporary frameworks for organizational intelligence design (Kolbjørnsrud, 2024).

4.2 Practical Applications for Organizational Development

The research provides specific guidance for developing transformative intelligence capabilities across organizational levels. Leadership development programs should integrate cognitive flexibility training with psychological flexibility interventions, moving beyond traditional focus on analytical skills to include emotional regulation, values clarification, and adaptive thinking capabilities (Kuo et al., 2018). Recent evidence demonstrates that organization-wide psychological flexibility training can significantly improve workforce resilience and performance, suggesting scalable approaches for transformative intelligence development (Archer et al., 2024).

Selection and promotion criteria should incorporate transformative intelligence assessments alongside traditional competency evaluations. The research suggests that leaders with high transformative intelligence create positive spillover effects throughout their organizational units, making these capabilities valuable for organizational performance beyond individual effectiveness. This approach aligns with contemporary research on balancing employee flexibility and organizational performance, particularly in innovation and productivity outcomes (Eng et al., 2025).

Organizational design implications include creating decision-making processes that support rather than inhibit transformative intelligence expression. This includes reducing time pressures that promote reliance on heuristics, creating diverse decision-making teams that challenge individual biases, and establishing feedback mechanisms that enable continuous improvement in decision-making processes. Contemporary frameworks for intelligent organization design provide additional guidance for implementing systematic approaches to human-cognitive capability collaboration (Kolbjørnsrud, 2024).

4.3 Integration with Existing Decision-Making Research

The findings integrate with existing research on cognitive biases in organizational settings while extending understanding of mitigation mechanisms. While previous research has documented extensive bias effects in managerial decision-making (Montibeller & von Winterfeldt, 2015), this study identifies specific capabilities that enable bias recognition and reduction in applied organizational contexts.

The role of psychological flexibility extends existing research on acceptance and commitment approaches in organizational settings by demonstrating specific mechanisms through which these capabilities improve decision-making effectiveness (Hayes et al., 2006). The research provides empirical support for integrated approaches combining cognitive and psychological interventions for managerial development.

4.4 Limitations and Future Research Directions

The study's focus on special education committees, while providing rich context for examining complex decision-making, may limit generalizability to other organizational contexts. Future research should examine transformative intelligence effects across diverse industries and organizational types to establish broader applicability of these findings.

The cross-sectional nature of quantitative assessments limits understanding of how transformative intelligence capabilities develop over time and respond to organizational interventions. Longitudinal research tracking capability development and decision-making improvements would provide valuable insights for leadership development practice, building on recent evidence for the effectiveness of systematic psychological flexibility interventions (Archer et al., 2024).

Sample size limitations, particularly for the high-transformative intelligence group (17.3% of sample), restrict statistical power for examining interaction effects and moderating variables. Larger-scale studies would enable more sophisticated analyses of factors influencing transformative intelligence effectiveness across different organizational contexts, potentially incorporating principles from contemporary organizational intelligence design frameworks (Kolbjørnsrud, 2024).

Future research should explore the integration of transformative intelligence with emerging organizational flexibility models, particularly examining how different flexibility profiles (flexible dividers, non-flexible dividers, etc.) relate to transformative intelligence capabilities and organizational outcomes (Eng et al., 2025).

Conclusions

This research demonstrates that transformative intelligence provides a valuable framework for enhancing decision-making effectiveness in complex organizational systems. The integration of cognitive

flexibility, psychological flexibility, and values-based decision-making creates capabilities that enable leaders to recognize and reduce cognitive biases, adapt to changing circumstances, and generate innovative solutions to organizational challenges.

The finding that psychological flexibility mediates relationships between cognitive capabilities and decision-making effectiveness suggests that effective leadership development requires integrated approaches addressing both analytical thinking skills and psychological adaptability. Organizations investing in transformative intelligence development can expect improvements in decision quality, adaptive capacity, and innovative problem-solving across management levels.

The emergence of organizational meta-capability when multiple leaders demonstrate transformative intelligence indicates potential for systematic transformation of organizational decision-making processes. This suggests that transformative intelligence development should be approached as an organizational rather than individual intervention, with systems-level support for capability cultivation and expression, consistent with contemporary frameworks for designing intelligent organizations (Kolbjørnsrud, 2024).

Future research should focus on developing and testing specific interventions for cultivating transformative intelligence capabilities, examining long-term effects on organizational performance, and exploring applications across diverse organizational contexts. The ultimate goal involves creating organizational conditions where transformative intelligence can flourish, enabling sustainable improvements in decision-making effectiveness and organizational adaptability in increasingly complex business environments.

Transformative Intelligence in Decision-Making Processes and Policy Implementation Management: An Integrated Framework for Organizational Process Optimization in Complex Systems

***Hila* Fuchs**[1,*]

[1] Gaia College – Academy of Applied Science and Technology, Faculty of Education, Jerusalem, Israel

Abstract

Research background: Contemporary organizational environments face unprecedented complexity requiring decision-making frameworks that transcend traditional rational models. Cognitive biases systematically compromise decision quality in multidisciplinary professional contexts where technical expertise must integrate with ethical judgment.
Purpose of the article: This study explores transformative intelligence theory as a comprehensive framework for improving decision-making quality in complex systems, specifically examining Israeli special education committees as exemplars of multidisciplinary professional contexts.
Methods: A convergent parallel mixed-methods design examined 60 committee chairs and 87 multidisciplinary committee members, supplemented by systematic content analysis of 350 committee minutes from 2019-2023. Transformative intelligence was operationalized through four integrated components: perceptual flexibility, adaptive functioning, ecological engagement, and transformative creativity.
Findings & Value added: Cognitive biases manifested in 73-82% of committee decisions, with representativeness, availability, and anchoring heuristics significantly impacting decision quality. Transformative intelligence components collectively explained 67% of variance in decision-making effectiveness ($R^2 = .67$, $F(4,55) = 27.8$, $p < .001$), with psychological flexibility mediating 61% of total effects. Participants scoring high on all components (17.3% of sample) demonstrated synergistic performance improvements with exceptionally large effect sizes ($d = 3.8$-4.6).

Keywords: Transformative intelligence, Decision-making, Cognitive biases, Psychological flexibility

JEL classification: M51; O15; J24

1. Introduction

Organizational environments face unprecedented complexity due to rapid technological advances, climate change, geopolitical uncertainty, and evolving social dynamics. This complexity manifests in decision-making systems where traditional rational models, developed under conditions of relative stability, prove inadequate for addressing interconnected challenges requiring simultaneous integration of technical, ethical, budgetary, and social considerations (Kahneman, 2011). Research demonstrates that up to 70% of organizational change initiatives fail, while 60% of public policy implementations fail to achieve stated goals, often due to fundamental mismatches between complexity demands and existing cognitive capabilities (Tversky & Kahneman, 1974). Recent research has challenged the widely-cited 70% failure rate as an unsubstantiated myth lacking empirical evidence, with scholars noting this figure has no credible scientific foundation and may be useful primarily for management consultants rather than reflecting actual organizational reality (Hughes, 2024).

Contemporary research reveals a complex, multidimensional structure underlying heuristics and biases, with recent studies showing that different biases relate to each other in nuanced ways, and that cognitive structure underlying these biases can be investigated through individual differences approaches (Berthet et al., 2022; Burgoyne et al., 2023). More than 180 cognitive biases have been identified over six decades of research in cognitive science, with this list continually evolving and requiring deeper study to understand their mechanisms and dynamics in both human and AI systems (Vakali & Tantalaki, 2024). A systematic review across four occupational areas confirms that professionals use heuristics to cope with

[*] Corresponding author: hila.ariel@gmail.com

complex and uncertain environments, which may result in inappropriate or suboptimal decisions, though the mechanisms behind cognitive biases still require further study (Berthet, 2022).

Recent research on organization design reveals that decision-making structures can have unintended organizational-level consequences, with structures effective at information aggregation not necessarily fostering individual learning (Joseph & Sengul, 2025). Additionally, complexity theory applications in organizational and management research demonstrate that complex systems span multiple scales, from industries and markets to firms and individuals, requiring dynamic and systemic methodological approaches (Cincotti et al., 2024). Modern decision-making systems operate in three critical dimensions challenging traditional approaches. First, increasing problem complexity requires managing interdependent factors with multi-level effects and non-linear dynamics leading to uncertainty and unexpected outcomes. Second, accelerated change pace demands rapid response capability while maintaining analytical depth and quality. Third, multidisciplinary challenges require integrating knowledge and perspectives across different fields and cultural contexts (Holland, 1995).

A 2022 systematic review across four occupational areas confirms that professionals use heuristics to cope with complex and uncertain environments, which may result in inappropriate or suboptimal decisions, though the mechanisms behind cognitive biases still require further study (Berthet, 2022).

Recent research on organization design reveals that decision-making structures can have unintended organizational-level consequences, with structures effective at information aggregation not necessarily fostering individual learning (Joseph & Sengul, 2025). Additionally, complexity theory applications in organizational and management research demonstrate that complex systems span multiple scales, from industries and markets to firms and individuals, requiring dynamic and systemic methodological approaches (Journal of Cincotti et al., 2024).

Modern decision-making systems operate in three critical dimensions challenging traditional approaches. First, increasing problem complexity requires managing interdependent factors with multi-level effects and non-linear dynamics leading to uncertainty and unexpected outcomes. Second, accelerated change pace demands rapid response capability while maintaining analytical depth and quality. Third, multidisciplinary challenges require integrating knowledge and perspectives across different fields and cultural contexts (Holland, 1995).

The Israeli special education system provides a particularly instructive case study. Amendment 11 to the Special Education Law (2019) aimed to shift from medical to social conceptions of disability, emphasizing inclusion and equal opportunities. However, implementation led to a 35% increase in students eligible for special education services and a 68% budget increase, raising fundamental questions about decision-making quality and system efficiency. Preliminary findings indicate that 94.7% of committee chairs cope with frequent policy changes, 89.2% report gaps between formal clarity and actual complexity, and 87.3% identify significant knowledge gaps among committee members.

Classical rational approaches, based on complete information and linear logical processing, fal in systems characterized by incomplete and variable information where decision effects unfold unpredictably over time and context (Kahneman & Tversky, 2000). Research reveals systematic patterns in decision errors through three key heuristics: representativeness heuristic leading to oversimplified categorization based on superficial similarities while ignoring base rates; availability heuristic causing over-reliance on easily retrievable information; and anchoring heuristic creating fixation on initial judgments inappropriately influencing subsequent evaluation (Stanovich, 2011).

This research proposes transformative intelligence theory as an integrated framework addressing existing decision-making approach limitations. Transformative intelligence is defined as meta-systemic ability to recognize, understand, and modify dynamic interactions between reality perception and functioning, enabling adaptive and generative responses to complex changing environments. This conceptualization extends beyond traditional intelligence frameworks (Sternberg, 2019) to encompass adaptive capabilities that transcend context-specific competencies. The theoretical framework integrates four core components: perceptual flexibility representing metacognitive ability to identify, evaluate, and change meaning-making frameworks while maintaining psychological coherence; adaptive functioning encompassing response regulation across functional domains based on contextual demands; ecological engagement involving understanding, managing, and influencing complex systems while recognizing interdependencies; and transformative creativity representing the ability to develop solutions transforming existing constraints into opportunities. These components align with broader frameworks emphasizing character strengths and virtues as foundational to human excellence (Peterson & Seligman, 2004).

2. Methods

2.1 Research Design

This study employed a convergent parallel mixed-methods design (Creswell & Plano Clark, 2017) to investigate relationships between transformative intelligence components and decision-making quality in complex organizational systems. The research was anchored in a pragmatic philosophical framework emphasizing practical outcomes while applying methodological rigor to both quantitative and qualitative data collection and analysis.

2.2 Participants

The research population consisted of two primary cohorts recruited through purposive and snowball sampling strategies. The primary cohort included 60 special education eligibility and characterization committee chairs with inclusion criteria of at least three years committee leadership experience, participation in 120 hours mandatory annual training programs, and actively chairing three to five committee meetings weekly. Demographic analysis revealed 85% (n = 51) female participants, with mean age of 49.63 years (SD = 4.2), all holding master's level academic degrees with 15-20 years special education experience.

The secondary cohort included 87 multidisciplinary committee members representing five professional groups: school psychologists (n=28, 32.2%), special education consultants (n=34, 39.1%), community school consultants (n=6, 6.9%), parent organization representatives (n=13, 14.9%), and general school counselors (n=6, 6.9%). This cohort consisted of 88.5% females (n = 77) with mean age of 43.72 years (SD = 6.8).

2.3 Data Collection Instruments

Quantitative Measures

Psychological flexibility was assessed using the Acceptance and Action Questionnaire-II (AAQ-II; Bond et al., 2011), demonstrating robust psychometric properties with Cronbach's $\alpha = .91$ in the current sample. The Transformative Intelligence Component Scale was developed specifically for this study, comprising four subscales: perceptual flexibility (8 items, $\alpha = .89$), adaptive functioning (10 items, $\alpha = .92$), ecological engagement (7 items, $\alpha = .87$), and transformative creativity (9 items, $\alpha = .90$). Confirmatory factor analysis supported the hypothesized four-factor structure ($\chi^2/df = 2.14$, CFI = .94, RMSEA = .07).

The Quality of Decision-Making Index represented a composite measure integrating multiple effectiveness indicators, emphasizing functional diagnosis accuracy and cognitive bias reduction. Inter-rater reliability exceeded .85 across all dimensions.

Qualitative Data Sources

Systematic content analysis was conducted on 350 committee meeting minutes spanning 2019-2023, representing approximately 14% of all regional committee meetings. Semi-structured interviews explored participants' perceptions of committee processes, decision-making challenges, and professional development needs through carefully constructed open-ended questionnaires.

2.4 Data Analysis

Statistical analyses employed hierarchical multiple regression examining relationships between transformative intelligence components and decision-making outcomes, with systematic adjustment for demographic variables and professional experience indicators. Missing data (3.2% of total dataset) were addressed through multiple imputation using MICE algorithm. Committee meeting transcripts underwent systematic thematic analysis following Braun and Clarke's (2006) six-stage analytical framework. Inter-coder reliability achieved $\kappa = .82$ across all primary themes.

2.5 Ethical Considerations

Comprehensive ethical approval was obtained from institutional review board, supplemented by Department of Education Research Committee authorization. Informed consent was obtained from all participants with particular attention to maintaining student and family confidentiality. All data were stored in encrypted systems accessible exclusively to research team members.

3. Research Findings

3.1 Manifestation of Cognitive Biases

Qualitative analysis of 350 committee transcripts revealed pervasive cognitive bias patterns systematically influencing decision-making quality across multiple dimensions. The representativeness

heuristic was observed in 73.2% of analyzed cases (n = 256), characterized by overreliance on superficial academic performance indicators despite comprehensive multidimensional student presentations. The availability heuristic demonstrated greatest influence, occurring in 79.3% of cases where dramatic or emotionally salient past cases inappropriately influenced current decisions regardless of contextual relevance (d = 1.41, large effect). Anchoring effects were most prevalent at 81.7% frequency, indicating initial assessment information had disproportionate impact on overall deliberative processes despite conflicting evidence presentation (d = 1.52, large effect).

Table 1. Cognitive Bias Frequency and Impact on Decision Quality

Bias Type	Frequency	95% CI	Effect on Decision Quality†	Cohen's d
Representativeness	73.2%	[68.1, 78.3]	-2.14***	1.23
Availability	79.3%	[74.6, 84.0]	-2.31***	1.41
Anchoring	81.7%	[77.2, 86.2]	-2.45***	1.52

*Note: Decision quality measured on 5-point scale. ***p < .001*
Source: the researcher

Secondary analysis identified socio-psychological factors reinforcing individual cognitive limitations through group interaction processes. Contrast effects influenced 43.7% of sequential case reviews (n=153), with severity ratings systematically biased by previous case characteristics ($F(1,348) = 24.7$, $p < .001$, $\eta^2 = .07$). Groupthink phenomena occurred in 71.4% of committee meetings (n = 250), particularly when discussions exceeded planned duration ($r = .34$, $p < .001$) or dominant authority figures discouraged dissenting views ($r = .41$, $p < .001$).

3.2 Transformative Intelligence Predictive Validity

Hierarchical regression analysis revealed significant relationships between all transformative intelligence components and decision quality indicators, with the full model explaining 67% of variance in overall decision quality ($R^2 = .67$, $F(4,55) = 27.8$, $p < .001$). Each component contributed unique variance in decision outcomes, supporting conceptualization of transformative intelligence as distinct but interrelated cognitive abilities.

Table 2. Transformative Intelligence Components Predicting Decision Quality

Predictor		E			p	r^2
Perceptual Flexibility	42	08	38	.25	<.001	18
Adaptive Functioning	35	09	31	.89	<.001	14
Ecological Engagement	29	07	27	.14	<.001	12
Transformative Creativity	33	08	29	.13	<.001	13

Note: sr^2 = squared semi-partial correlation (unique variance explained)
Source: the researcher

Perceptual flexibility emerged as the strongest predictor ($\beta = 0.38$, $p < 0.001$), accounting for 18% unique variance in outcomes. This component demonstrated particular effectiveness in bias identification capabilities ($r = .72$, $p < .001$) and perspective-taking ability ($r = .68$, $p < .001$).

3.3 Psychological Flexibility Mediation

Bootstrap mediation analysis with 5,000 replicate samples examined psychological flexibility's mediating role between transformative intelligence components and decision outcomes. Results provided robust support for significant indirect effects across theoretical pathways.

Psychological flexibility mediation model:

- Overall effect (c): .62***
- Direct effect (c'): .24*
- Indirect effect (ab): .38, 95% CI [.28, .52]
- Proportion of mediated effects: 61%
- Model R^2: .73

The mediation model explained 73% of variance in decision quality, with psychological flexibility mediating 61% of total transformative intelligence effects on decision outcomes. This substantial mediation suggests transformative intelligence improves decision-making primarily through increased psychological flexibility.

3.4 Synergistic Effects Analysis

Analysis of participants scoring above 75th percentile on all four transformative intelligence components (n=11, 18.3% of sample) revealed synergistic effects exceeding additive predictions. This elite group achieved 89.2% accuracy in bias identification compared to 34.7% in low transformative intelligence groups, with opinion changes following contradictory evidence occurring 78.4% versus 23.8% respectively. Effect sizes for these comparisons ranged from $d = 3.8$ to $d = 4.6$, indicating exceptional practical significance.

4. Discussion

4.1 Transformative Intelligence as Integrated Framework

The strong predictive power of transformative intelligence components, explaining 67% of decision-making quality variance, provides empirical support for theoretical frameworks proposing that human functioning emerges through dynamic integration across multiple domains rather than isolated abilities. The synergistic effects observed when all components operate at high levels provide empirical support for the theoretical proposition that human abilities arise from multiplicative rather than additive interactions between functional domains.

4.2 Psychological Flexibility as Mediating Mechanism

The mediating role of psychological flexibility, accounting for 61% of total effects linking transformative intelligence to decision outcomes, provides critical insight into mechanisms underlying effective decision-making in complex environments. This finding extends acceptance-based therapeutic frameworks to organizational effectiveness domains while providing empirical support for psychological flexibility's transdiagnostic nature across different life contexts (Hayes et al., 2006).

Committee members exhibiting higher psychological flexibility demonstrated improved ability to recognize existing approach limitations while remaining open to innovative solutions. This finding relates to broader research on mindfulness and contemplative practices in organizations, suggesting that organizations seeking improved decision-making capabilities should incorporate contemplative approaches alongside technical training.

4.3 Practical Implications

The research findings suggest fundamental reconceptualization of educational approaches at all levels, from early childhood to continuing professional development. Traditional educational models emphasizing knowledge transmission and skill acquisition appear insufficient for developing integrated capabilities needed to meet contemporary challenges. Developing transformative intelligence requires

educational approaches cultivating metacognitive awareness, emotional regulation, social collaboration, and creative problem-solving within integrated learning experiences.

Organizations seeking enhanced decision-making effectiveness should consider implementing integrated development programs addressing all four transformative intelligence components. However, synergistic effects observed suggest these components need coordinated rather than isolated development. Organizational climate results indicate structural and cultural factors significantly influence individual capability expression.

4.4 Limitations and Future Research

Several methodological limitations warrant acknowledgment. The sample's focus on Israeli special education committees limits generalizability to other cultural and organizational contexts. The cross-sectional design precludes definitive causal inferences about transformative intelligence developmental trajectories. Self-report assessment of transformative intelligence introduces potential response bias, partially mitigated through anonymous data collection and triangulation with behavioral indicators.

Future research requires extensive cross-cultural validation and longitudinal studies examining transformative intelligence development across different career trajectories and life stages. Intervention studies testing specific training approaches should include randomized controlled trials comparing transformative intelligence-based development with traditional professional training approaches.

Conclusion

This research provides empirical validation of the transformative intelligence framework while demonstrating that systematic capability development can significantly enhance decision-making capacity and reduce cognitive bias susceptibility. The discovery of synergistic effects when all components operate at high levels suggests transformative intelligence represents an emergent capability transcending traditional conceptualizations of human intelligence and competence.

The mediating role of psychological flexibility provides critical insight into effective decision-making mechanisms, establishing links between individual psychological processes and collective effectiveness outcomes. Most importantly, research demonstrates that cognitive and emotional limitations constraining human decision-making are not fixed barriers but challenges overcome through systematic capability development in appropriate organizational and cultural contexts.

As humanity faces increasingly complex challenges requiring integration of technical expertise with wisdom, compassion, and creative innovation, developing transformative intelligence capabilities becomes essential for collective flourishing. The research provides both theoretical foundation and practical guidance for this development, recognizing the journey involves continuous learning, adaptation, and growth without fixed endpoints.

The Effect of Self-Efficacy and Perceived Career Threats on Attitude Towards Parental Leave

Petia **Genkova**[1,*] **and** ***Tim*** **Speckmann**[1]

[1] University of Applied Sciences Osnabrück, Faculty of Business Management and Social Sciences, Osnabrück, Germany

Abstract

Research background: Taking time for parental leave to fully embrace their live as a family is important for the majority of German employees. Current literature shows that the decision regarding parental leave is influenced by different factors, such as income or workplace factors, but does not consider potential interaction effects and attitude towards parental leave.
Purpose of the article: This study addresses key topics in Human Resource Management and Organizational Behavior by examining the interaction between self-efficacy and perceived career threats as predictors of participants' attitude toward parental leave, as well as family involvement and traditional gender role attitude as potential moderators.
Methods: Using a cross-sectional survey design and quantitative methods, data was analyzed through Welch´s test and moderation analysis.
Findings & Value added: Using quantitative methods, the results of a Welch-test indicate that there is a significant difference between men and women, whereas women have a more positive attitude toward parental leave. Further, by using moderation analysis, a negative relationship between perceived career threats and attitude toward parental leave was shown, moderated respectively by family involvement and traditional gender role attitude. There was a positive relationship between self-efficacy and attitude toward parental leave, moderated by traditional gender role attitude but not by family involvement. The results indicate that the difference in utilization of parental leave attitude is also reflected in different attitude toward parental leave between the genders. Further individual views and opinions about family seem to be essential in questions regarding parental leave.

Keywords: Parental leave, Self-efficacy, Career threats, Gender roles, Family involvement

JEL classification: J13, J16, M12

1. Introduction

The importance of parental leave grows rapidly in German society and also as a topic in companies. Besides of work-family compatibility, the main goal is equality between the sexes (BiB, 2022). Due to the pandemic, women often did the majority of childcare work, they reduced their working hours more than men and in general the psychological load within the family due to work-family compatibility increased (BMFSFJ, 2021). Families in Germany suffer significantly more from the increasing prices, which occur due to the war in the Ukraine and as a matter of fact, cuts in income aren't possible for many (BMFSFJ, 2023). This highlights the importance of parental leave, as covid as well as the inflation harden the situation. Understanding attitudes towards parental leave is essential for HR managers and organizational leaders aiming to design effective work-family policies and promote gender equality in the workplace.

Parental leave is considered as time off work for new parents who want to look after their children themselves and embrace their family life. Employees in Germany can request this for up to three years in total. To compensate cuts in income, parents also have the opportunity to receive parental allowance for up to twelve months and additionally for extra two months exclusively when both parents reduce their working hours (so called "Partnermonate"; BMFSFJ, 2022).

[*] Corresponding author: petia@genkova.de

Since 2006, fathers' utilization of parental leave in Germany has increased from 3.6 % to 42.1% in 2018. Yet the majority (75.4 %) only uses the exclusive months. On the other hand, 94 % of women in Germany use parental leave for at least 10 months (Statistisches Bundesamt, 2021; Eng.: German Federal Statistical Office). This shows a clear gap between men and women regarding parental leave in Germany. According to social role theory (Eagly, 1987), prevailing social gender stereotypes are responsible for different behaviors and attitudes of men and women through social pressure and societal expectations of individuals (Eagly & Wood, 2012).

Both men and women want to be successful in their profession while also meeting the needs of their family life (Wiese, 2005). Yet research shows, that women reduce their working hours to take care of their family more often, especially with regard to parental leave (Maume, 2006). Literature demonstrates that negative career consequences follow longer career breaks, such as wage reduction (Lequien, 2012). This indicates that parental leave is a question of career management due to its long-lasting impact on the career (Horvath et al., 2018).

Research examined factors which explain the observed gap such as income or workplace factors, to address career and equality issues and to limit the impact of longer career breaks (e.g., Berrigan, 2018). Attitude toward parental leave only has been investigated sporadically. As meta-analyses show that there is a clear relationship between attitude and actual behavior and that attitude significantly predicts behavior (e.g., Glasman & Albarracín, 2006), attitude toward parental leave and different predictors of this attitude should be considered when facing the problem of parental leave.

The career self-management model (CSM; Lent & Brown, 2013), which is based on the social cognitive career theory (Lent et al., 1994) assumes that individual and contextual factors are necessary to manage professional developmental tasks and unforeseen events (e.g., job loss). With this model, a wide array of professional events, such as parental leave, can be analysed. Self-efficacy and the expected effects of one's own behavior are the two cognitive-personal factors within this model (Lent & Brown, 2013), which can both be transferred to parental leave.

When considering CSM and social role theory, effects on attitude toward parental leave may be explained by factors of these theoretical approaches. As previous studies on parental leave didn't focus on attitude, it is still unclear, whether subjectively perceived external factors and self-efficacy play a role regarding attitude towards parental leave. Including the importance of family and gender stereotypes as moderators, in consideration of CSM and social role theory, is thus legitimate.

Therefore, we investigate the research questions in how far attitude toward parental leave is related to perceived career threats and self-efficacy, and whether gender role attitude and family involvement may have a moderating role in these relationships. Moreover, gender differences in the attitude toward parental leave will be examined. In the following section, we outline the theoretical framework for our research questions and present the generated hypotheses.

1.1 Attitude toward parental leave, Gender roles and family involvement

People's ideas and beliefs about parenthood, gender roles, and family play an essential role in relation to parental leave. A person has many different roles in their life. These different roles are directly related to each other, so that one role might be more important than another. Both, men and women rate family roles as more important than work roles. Yet, at the same time, men consider work roles as more important than women, while the latter assign higher importance to other roles (Reitzes & Mutran, 2016).

These differences might result in different behavior with regard to family and career. For example, the socially defined role of a mother is much more demanding for a woman than the role of a father for a man. A reduction of working hours caused by family demands is more likely and more frequent for women – this is also partly independent of the prevailing gender role attitude in respective families (Maume, 2006).

A representative German study showed that 12 % of men from Western-Germany can imagine taking parental leave for longer than six months, whereas 83 % of women would take parental leave for at least one year (Allmendinger et al., 2013). Various studies show that, especially for fathers, negative career expectations are a main reason against parental leave (BMFSFJ, 2018).

Based on these results presented, we hypothesize:

H1: Women have a more positive attitude toward parental leave than men.

The views on gender roles play a decisive role in the consideration of parental leave. Many studies show that a modern understanding of gender roles is positively related to an equal division of parental leave (Maume, 2008) and childcare (Bulanda, 2004). However, the operationalization was rather

heterogenous. In our study, we used operationalization from Braun (1999), who distinguishes between modern and traditional gender roles. Traditional meaning women caring for their families and men being breadwinner; modern gender roles meaning both partners care for their family.

Vogt and Pull (2010) showed that modern gender role attitude increases the probability of taking parental leave. Studies also showed such a correlation for attitude toward parental leave (e.g., Miyajima & Yamaguchi, 2017). These results are in line with social role theory, which attributes differences in behavior between men and women to gender role differences (Eagly & Wood, 2012). We anticipate a moderation effect as the relationship between different factors and attitude towards parental leave will depend on individual's views on gender roles.

Based on the findings on value differences between men and women regarding family and work roles, we assume that the importance of family for one's own life is important with regard to parental leave. We assume that family involvement plays a central role in the evaluation of potential parental leave. Following Duvander (2014), this study operationalizes the importance of one's mother/father role with the construct family involvement. Duvander (2014) demonstrated that family involvement of women is related to the length of parental leave. Analogously, Brandt (2017) showed that family involvement of men is associated with a higher probability and length of taking parental leave.

Vogt and Pull (2010) highlighted the relevance of family involvement and examined it as a moderator for the relationship between the Big Five and the use of parental leave. However, no moderating effect could be identified. Thus, the effect of family involvement isn't clear yet. Unless their results, we follow their assumption and assume a moderating effect of family involvement.

1.2 Perceived threat for the career

The already mentioned CSM is suitable to explain behavior which affects careers in a long-lasting manner. Horvath et al. (2018) already used this model regarding parental leave. The expected effects of one's own behavior are the expected obstacles to one's own career after returning to work from parental leave (Vogt & Pull, 2010) as well as expected occupational risks that may be associated with parental leave (Wiese, 2005). Studies showed that the use and duration of parental leave is highly dependent on previously anticipated career obstacles and general risks to one's career (Vogt & Pull, 2010; Wiese, 2005). A representative study was able to show that for men, negative career expectations are often an important reason against taking parental leave (BMFSFJ, 2018). In line with CSM as well as previous findings, we thus expect:

H2: There is a negative relationship between perceived career threats and attitude toward parental leave.

H2a: Family involvement moderates the relationship between perceived career threats and attitude toward parental leave. With low expressions of family involvement there is a stronger negative relationship between perceived career threats and attitude toward parental leave.

H2b: Traditional gender role attitude moderates the relationship between perceived career threats and attitude toward parental leave. With high expressions of traditional gender role attitude there is a stronger negative relationship between perceived career threats and attitude toward parental leave.

1.3 Self-efficacy

The second predictor within CSM is self-efficacy, which is the personal conviction of being able to use the own skills to show certain behavior (Lent & Brown, 2013). In their study, Horvath et al. (2018) examined self-efficacy as a possible predictor for parental leave. However, no effects of self-efficacy on planned and actual length of the parental leave were found. Instead, self-efficacy was found to affect the planned length and the return experience after parental leave. Individuals with high self-efficacy manage their return more successfully (e.g., less stress; Wiese & Heidemeier, 2012).

The relationship between self-efficacy and attitude toward parental leave hasn't been investigated properly yet. Based on the CSM, it can be expected that individuals who are convinced of themselves and their abilities are happy to take on a new "challenge" and are thus positively disposed to the possibility of parental leave. Further this relationship could be moderated by family involvement and traditional gender role attitude based on our consideration set out above.

H3: There is a positive relationship between self-efficacy and attitude toward parental leave.

H3a: Family involvement moderates the relationship between self-efficacy and attitude toward parental leave. With high expressions of family involvement there is a stronger positive relationship between self-efficacy and attitude toward parental leave.

H3b: Traditional gender role attitude moderates the relationship of self-efficacy and attitude toward parental leave. With low expressions of traditional gender role attitude there is a stronger positive relationship between self-efficacy and attitude toward parental leave.

2. Methods

2.1 Sample, procedure and study design

Before data collection, the minimum sample size was determined with the tool G-Power. Based on the planned analysis methods (Welch-test and moderation analyses) with a statistical power of .95 a sample size of 250 participants was intended.

In total, the data consists of 345 participants, yet 84 did not finish the questionnaire, so they were excluded from further analysis. The other 261 participants filled out the survey completely.

The sample consists of 102 men (39.1%) and 159 women (60.9%). The age of the participants ranged from 17 to 86 years. The mean age was 31 years (*SD* = 12.18). There were no participants without or a secondary school diploma. Twenty-five individuals (9.6%) stated that their highest level of education was “mittlere Reife” (which is similar to GCSE). The highest educational qualification of 74 individuals (28.4%) was “Abitur” (similar to A-levels). Another 61 people (23.4%) had completed vocational training, and 48 individuals (18.4%) had completed a bachelor’s degree. Forty-five individuals (17.2%) indicated a completed master’s degree and seven individuals (2.7%) a doctorate as their highest educational qualification.

The online survey was developed with LimeSurvey and it was distributed through various social media channels, such as LinkedIn or Facebook, and by email newsletters. Potential participants were provided with a link to the online questionnaire. It was possible to complete the questionnaire on smartphone or computer. No material incentives were provided for participation.

The participants were informed that by taking part in the survey they were agreeing to their anonymized data being used solely for scientific purposes. Further, they were informed that their participation was voluntary and that there was the possibility to quit the survey at any time without disadvantages for them. Participants were asked to answer the questions in an honest and spontaneous manner. After the participants gave their consent, they were redirected to the questionnaire.

2.2 Measurement instruments

Attitude toward parental leave was assessed with five items based on Miyajima and Yamaguchi (2017) on a 6-point Likert scale. All items were rephrased for gender neutrality and into German, as the original items were in English and designed to assess attitude toward parental exclusively for fathers. The items had a very good internal consistency (α = .92).

Perceived threat and risks regarding one’s own career which are connected to parental leave were assessed by two scales. Based on Vogt and Pull (2010), career threats connected to parental leave were assessed by six items which were answered on a 5-point Likert scale. As the original items were also specifically for fathers, they were rephrased to be applicable for both men and women. Possible risks were assessed based on Wiese (2005) on a 4-point Likert scale. The original items had been formulated for female managers and were also rephrased for this study. Internal consistency was good (α = .86).

To measure self-efficacy, the general self-efficacy expectancy scale of Schwarzer and Jerusalem (2003) was used. It included ten items, which were rated on a 4-point Likert scale. In this study internal consistency could be rated as acceptable (α = .76).

Family involvement was measured with a scale by Frone et al. (1992) and Frone and Rice (1987). They developed their items based on the work involvement scale of Kanungo (1982) by rephrasing it to fit a family context. The items were translated into German for this study. The four items had an acceptable internal consistency (α = .77).

Attitude regarding traditional gender roles were assessed using Braun's (1999) Gender Role Scale (ISSP 94). On a 5-point Likert scale, a total of eleven items were answered which had an acceptable internal consistency (α = .79).

3. Results

Table 1 shows an overview of the means and standard deviations of the different variables. In addition, the intercorrelations and Cronbach’s alpha values are shown.

Table 1. Means, standard deviations, correlations and internal consistencies

Variable	*M*	*SD*	1	2	3	4
1. Attitude toward parental leave	5.13	.91	*.92*			
2. Career risks and threats	2.64	.51	-.56**	*.86*		
3. Family involvement	3.01	.64	.50**	-.40**	*.77*	
4. Traditional gender role attitude	3.98	.59	-.44**	.25**	-.24**	*.74*

Notes. The arithmetic mean, the standard deviation and the intercorrelations of the variables are shown; ** $p < 0.01$ (two-sided); * $p < .05$ (two-sided); the internal consistency (Cronbach's alpha) is shown in the diagonal.
Source: author (2025)

To test Hypothesis 1, a Welch-test was conducted, as there was no homoscedasticity (tested with Levene-test; $p < .001$). Also, there was no normal distribution of the dependent variable. As the groups consisted of more than 25 individuals, the Welch-test is considered to be relatively robust against this kind of violation (Blanca et al., 2017). All the other requirements were met (outliers, scaling, independence of cases). The Welch-test showed a significant difference between men and women in their attitude toward parental leave ($t(260) = 65.45$; $p < .001$). Women ($M = 5.48$; $SD = .64$) had a significantly higher attitude toward parental leave than men ($M = 4.68$; $SD = .99$), supporting hypothesis 1. The effect size was $d = 1.13$, which is a large effect after Cohen (1988). Through the results presented, hypothesis 1 can be accepted that women have a more positive attitude toward parental leave than men. The mean value of women is higher and significantly different compared to the men within the sample.

Hypothesis 2 and 2a/b were tested with a moderation analysis using the PROCESS macro for SPSS (Model 2, 5000 bootstrap samples). The statistical requirements for regression analysis were all met after Hayes (2022; Residual independence, linearity, normal distribution of residuals, homoscedasticity). The overall model was significant ($F(5, 255) = 86.05$; $p < .001$); 53.66% of variance could be explained by this model, which is considered as a large effect by Cohen (1988).

The relationship between perceived career threats and risks and attitude toward parental leave was significant ($\beta = -.60$; $p < .001$, 95% CI [-0.77, -0.45]). Thus, hypothesis 2 could be supported. The interaction effect of the moderator family involvement was also significant ($\beta = .47$; $p < .001$, 95% CI [0.28, 0.66]; $\Delta R^2 = .03$), supporting hypothesis 2a.

The interaction effect of the moderator traditional gender role attitude was also significant ($\beta = -.33$; $p < .001$, 95% CI [-0.51, -0.17]; $\Delta R^2 = .016$). Hypothesis 2b was therefore supported.

The results indicate that perceived career threats correlate negatively with attitude toward parental leave. This is relationship is, further, moderated by both family involvement as well as traditional gender role attitude. For individuals with low expressions of family involvement or high expressions of traditional gender role attitude, there is a stronger negative relationship between perceived career threats and attitude toward parental leave. The results of the moderation analysis can be seen in table 2.

Table 2. Moderation analysis perceived career threats and attitude toward parental leave

Predictor	ΔR^2	β	*se*	*t*	*p*	BootLLCI	BootULCI
Constant		5.22	.04	120.12	.000	5.13	5.30
Career threats		-.60	.08	-7.52	.000	-0.77	-0.45
Family involvement		.34	.07	4.79	.000	0.20	0.46
Interaction_FI	.03	.55	.1	5.73	.000	0.28	0.66
Gender role attitude		-.37	.07	-5.59	.000	-0.50	-0.24
Interaction_GR	.016	.33	.09	-3.85	.000	-0.51	-0.17

Notes. Model: $F(5, 255) = 86.05$; $p < .001$; $R^2 = .5366$.
Source: author (2025)

Hypothesis 3 to 3b were tested by using moderation analyses with the PROCESS macro for SPSS (Model 2, 5000 bootstrap samples). Before the analysis, the requirements (Hayes, 2022) were tested and were all met. The results showed a significant overall model ($F(5, 255) = 35.84$; $p < .001$; $R^2 = .3987$) with a variance of 38.9% which is considered as a large effect by Cohen (1988). The relationship between

self-efficacy and attitude toward parental leave was significant (β = .32; p = .013, 95% CI [0.09, 0.57]), so that hypothesis 3 could be supported.

Family involvement was not found to be a significant moderator within the model (β = -.19; p = .429, 95% CI [-0.67, 0.21]; $\Delta R2$ = .003). Based on these results, hypothesis 3a was rejected.

The second moderator, traditional gender role attitude, was found to be significant (β = .57; p = .037, 95% CI [0.09, 1.1]; ΔR^2 = .017), supporting hypothesis 3b.

The analysis showed that Hypotheses 3 and 3b could be confirmed. This means that we were able to identify a positive correlation between self-efficacy and attitude toward parental leave. Further, traditional gender role attitude moderates this relationship by strengthening the positive relationship for individuals with low expressions of traditional gender role attitudes. Family involvement could not be confirmed as a moderator here. Results of the moderation analysis for Hypothesis 3 to 3b are shown in table 3.

Table 3. Moderation analysis self-efficacy and attitude toward parental leave

Predictor	ΔR^2	β	*se*	*t*	*p*	BootLLCI	BootULCI

4. Discussion

This study examined effects on attitude toward parental leave. We investigated differences between men and women as well as the relationship between attitude toward parental leave and perceived threats and self-efficacy. Further, we analyzed possible moderation effects of family involvement and gender role attitude.

Our hypothesis that women generally have a more positive attitude toward parental leave than men could be confirmed. Previous studies pointed out that there is a gap between men and women in Germany regarding parental leave. Whereas women mostly use parental leave for over a year, men tend to focus on their exclusive two months, while only a minority of men use parental leave. Our study showed that these observed behavioral differences are also seen in the attitude toward parental leave, confirming findings that behavior can be predicted by attitude (e.g., Glasman & Albarracín, 2006). This hypothesis confirms existing stereotypes regarding men and women and the division of childcare. They are in line with social role theory (Eagly, 1987), that social expectations are reflected in actions and attitudes. Although there are numerous measures for equality, men still have a more negative attitude than women. Yet it needs to be noted, that men's overall attitude is on a high level (M = 4.58). This can be explained by the different (financial) incentives here in Germany and it is also evident in the general increase in parental leave by fathers (Statistisches Bundesamt, 2021). In industries and occupational groups characterized by a high workload, parental leave is, nevertheless, not the common practice, especially for fathers and a leave for more than 2 months.

Based on CSM, perceived career threats and self-efficacy were investigated regarding their relationship toward parental leave. Parental leave is related to career management, as it can have a considerable impact on further career development (Hoff et al., 2002).

Results indicated that both, perceived career threats and self-efficacy are related to attitude toward parental leave. Individuals who perceived possible threats and risks as more likely had a significantly less positive attitude toward parental leave. Arguably, people who perceive more possible drawbacks connected to parental leave view it more negatively. Another explanation might be, that people who value their career success high, might be more likely to be aware of possible career threats connected to a longer period of work absence. As their work-life is very important to them, they don't want to risk their future career success and as a matter of fact don't take their chance of parental leave. On the other hand, when career doesn't matter much in people's lifes, they think about possible risks and even if there are

some down-sides regarding their career, they are absolutely willing to take these risks in order to take care of their children.

Further, individuals who have high self-efficacy have a more favorable attitude toward parental leave. A possible explanation for this is that these individuals perceive parental leave as another "challenge", while being convinced of their own abilities to successfully cope with it. Self-efficacy proved, thus, to be a cognitive resource in the handling of different challenging situations. Further it might be plausible that people with high self-efficacy are convinced of their own abilities and even if they can think of possible risks regarding parental leave and their career, they might believe that they can manage both and these risks don't apply to them in such a pronounced manner. Returning to their job after their leave, might also be seen as another "challenge" and they believe that they have the ability to be successful, despite their absence. In general, these results show that both individual resources (self-efficacy) as well as factors of the environment (perceived career threats) can have an influence on one's attitude toward parental leave and in the end on the decision for or against parental leave.

The moderation analysis showed that family involvement could only be partially proved as a moderator. Whereas family involvement moderates the relationship between perceived career threats and parental leave, there was no significant moderation effect for self-efficacy. This is a different result compared to the study by Vogt and Pull (2016), who were not able to find any moderation effect of family involvement at all. Our result suggests that family involvement can make a difference to some effects on parental leave, probably by changing the perception of the benefit-risk ratio associated with parental leave. As there is no moderation for self-efficacy, it can be assumed that the views regarding parental leave connected to one's ability to cope with this kind of situation are not associated with the importance of one's own family.

Traditional gender role attitude had a moderation effect regarding parental leave. Individuals with less traditional views were more likely to have less positive views on parental leave. For individuals with low traditional gender role attitude, the positive relationship between self-efficacy and attitude toward parental leave was stronger than for individuals with high traditional gender role attitude. However, the negative relationship between career obstacles and parental leave was stronger for individuals with more traditional attitude. The moderator traditional gender role attitude is therefore a promising construct to be further explored in future studies. An explanation for these results might be that views on traditions might have substantial impact on how people view certain aspects in their life's regardless of individual or contextual factors.

The present study expands the existing research on parental leave in many respects. The results of the present study support previous findings on factors related to parental leave (e.g., Berrigan, 2018; Horvath et al., 2018; Vogt & Pull, 2010). In particular, this study was able to establish the relation to perceived threats, gender role attitude, self-efficacy, and the importance attributed to family.

The finding from the study by Vogt and Pull (2010), demonstrating the relationship of perceived career threats and fathers' use of parental leave, could be supported by indicating a relationship between perceived career threats and attitude toward parental leave. Furthermore, the consideration by the authors that not only the perception of contextual and occupational factors play a role in the consideration, but also self-assessment, could be supported in the present study, since a connection between self-efficacy and parental leave could be identified, whilst Vogt and Pull (2010) were unable to verify this assumption in their study. Also, they were unable to verify the moderating effect of the subjective importance of the family. In contrast, the present study found a moderating effect of the subjective importance of the family. The different result could be explained with the scales' poor quality, whereas we operationalized all constructs with already peer-reviewed scales.

Horvath et al.'s (2018) assumption that parental leave is also a career management topic could be corroborated. Unlike in their study, a correlation between self-efficacy and parental leave was found. This may be due to different constructs. While Horvath et al. (2018) examined the actual use of parental leave, we focused on attitude toward parental leave. To better understand these different findings, future research should further investigate the relationship between self-efficacy and parental leave.

The results of this study were not representative for the total population (e.g., people in Germany), as we draw a convenience sample. Future research should draw a representative sample to demonstrate the robustness and external validity of the current findings. Additionally, no causal relationship can be deferred from these results, as this was a cross-sectional study. Future research should get closer to examining causal relationship by conducting longitudinal studies.

Another limitation of this study is that there is no normal distribution of the construct attitude toward parental leave. A possible reason for the very left-skewed distribution (ceiling effect) could be the construct attitude toward parental leave itself. More positive attitude toward parental leave can be expected because parental leave is a non-mandatory option and supposed to be a relief for parents. It can be assumed that people may be generally positive about parental leave and may generally value this opportunity for parents, even when it is not relevant for them personally.

Conclusion

This study provides important insights into the factors influencing attitudes toward parental leave, highlighting the roles of perceived career threats, self-efficacy, gender role attitudes, and family involvement, which are also highly relevant for Human Resource Management and Organizational Behaviour. The findings confirm and extend previous research, demonstrating that both individual and contextual factors shape parental leave attitudes. Although the study is limited by its non-representative sample and cross-sectional design, it lays the groundwork for future research to explore these relationships in more depth and with more robust methodologies. Overall, the results underscore the need for continued efforts to address barriers to parental leave and to promote more equitable sharing of family responsibilities.

Tax Management and the Effectiveness of Tax Crime Detection

***Miroslav* Gombár**[1], ***Nella* Svetozarovová**[1,*], **and *Anna* Burdová**[1]

[1] University of Prešov in Prešov, Department of Management, Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Tax crimes, including tax evasion, pose a serious threat to the financial stability of countries, undermine fair competition and reduce public revenues. In dynamically evolving tax systems, it is essential that tax administration management is able to adapt to new challenges, including the prevention and effective detection of tax crimes, with an emphasis on legislative measures and legal standards.
Purpose of the article: The aim of the study is to analyse the key performance indicators of the effectiveness of tax audits and crime detection with regard to the legal aspects regulating the tax procedure. The examination of legal frameworks and statistical relationships between efficiency indicators and legislative provisions provides suggestions for improving tax compliance in accordance with legal requirements.
Methods: The analysis uses secondary data from the summary reports of the tax offices of the Slovak Republic from 2017 to 2023, applying descriptive statistics and non-parametric tests (Friedman ANOVA) to verify statistically significant differences between the studied years in terms of selected indicators of tax audits, according to the data of the tax offices operating in the conditions of Slovakia.
Findings & Value added: The findings support the need for legislative and technological improvements and include recommendations to optimise processes, increase the efficiency of tax audits and harmonise legislation to improve tax compliance.

Keywords: Management, Tax administration, Tax crimes, Efficiency, Tax controls, Legal aspects

JEL classification: F38, G32, H2

1. Introduction

Tax administration management and the effective prevention of tax crimes are today key issues for ensuring the financial stability of the state and citizens' confidence in the tax system. In a globalised and digitalised environment, there is increasing pressure on tax administrations not only to manage tax collection efficiently, but also to detect tax evasion effectively and prevent illegal practices that can have a significant negative impact on public revenue and fair competition. These problems affect not only economic stability but also the public perception of the fairness of the tax system and thus the willingness of taxpayers to comply with their obligations. Ensuring effective management and development of the legal framework for tax administration is thus a necessity. Effective management of the tax administration involves not only the administration of taxes and the implementation of legislation, but also the prevention and detection of tax crimes that have a significant impact on the country's economy. In a context of constantly evolving tax systems and technologies, it is important that the tax administration is able to adapt to new challenges, including large-scale tax evasion and fraud. Against this background, it is clear that the issue of tax administration management is an inherent part of the modern tax system. Effective tax audit management can contribute not only to increasing public revenue but also to improving the overall credibility of the tax system. It is therefore essential to continue to explore this topic and to look for new approaches to increase the effectiveness of tax controls and prevent tax crimes.

1.1 The importance of tax administration in the context of tax crimes

Taxes affect our daily lives and every tax is part of the tax system. This system evolves with the economic and historical development of a country, leading to a specific tax structure for each country. Responsibility for meeting tax obligations lies with the recipient of the tax, known as the taxpayer. This role is assumed either by an individual (entrepreneur/non-entrepreneur) or by a legal entity. There are cases where the tax entity may include a legal representative, a tax guarantor or even a legal successor of the natural or legal person. In the context of tax-related legal relations, these tax entities are most commonly referred to as taxpayers and taxpayers. (Schultz et al., 2011) According to Lénartová (2015) she defines a taxpayer as an anonymous consumer who pays the tax in the price of the good or service purchased because the tax is part of the consumer price. A taxpayer is a tax entity that is legally obliged to remit to the public budget the tax collected from other entities or withheld by another taxpayer on the basis of its property liability (Vančurová, Láchová 2010). Within the concept of value added tax we encounter the concept of tax payer. It is any person who independently runs a business regardless of the purpose or results of this activity.

According to Smith (2022), tax liability refers to the legal responsibility of individuals or entities to pay taxes to the government in accordance with applicable laws and regulations. It includes the payment of taxes on income, property, sales, or other transactions imposed by the government. Tax liability forms the basis of a country's tax system and is the required contribution of citizens to finance public spending and services (Gombár et al. 2022, 2023). Tax revenue optimization refers to efforts to improve the efficiency and effectiveness of tax collection by the government. This includes implementing strategies and policies aimed at reducing tax non-compliance, strengthening law enforcement, and maximizing potential tax revenues. Optimizing tax revenue is essential to support the financial sustainability of the government and to fund various public programs and services. (Herawaty, 2021)

But, as a priority, taxes play a key role in maintaining the financial stability of the state because they are the main source of revenue that finances the various financing requirements of government (Setiyaji and Amir, 2005). Taxes fulfill recurrent obligations such as paying employees and covering operational costs, they play a key role in promoting sustainable development of the state. From this perspective, taxes play a key role in achieving development goals and building the necessary infrastructure for economic progress and social welfare. (Anwar, 2022) Tax is a legal requirement imposed by the government on individuals or entities. (Waluyo, 2009 In: Paroli, 2023) Tax administration itself is more than an administrative process; it is a key pillar of the social, legal as well as economic system. Certain essential ideas, which can be termed principles, are applied in the administration of taxes and fees and are determined by the applicable legislation. For a proper understanding of the meaning of the term tax administration, here are some definitions and definitions of selected domestic and foreign authors. Kostičová (2015) describes tax administration as a system of public authorities that ensures their administration, collection as well as supervision of their correct payment and collection. It is responsible for the application of tax laws and for the resolution of tax disputes. Bird (2004 In: Široký, 2011) attributes synonyms to the term, such as the institutional framework and organisational structure through which the state implements the execution of tax policy, including tax collection, control activities and the resolution of tax offences. It encompasses all activities related to the enforcement of tax laws, including the assessment, collection and administration of tax revenues. According to a similar definition, the tax administration is a public institution whose main function is to manage and control the collection of taxes in accordance with the legislation in force. Its activities include both administrative procedures and executive measures in securing state revenues. (Pálka, 2006) The procedural view of tax administration is stated by Alma (2012), in this way the government ensures compliance with its tax laws. This includes identification of taxpayers, determination of tax liabilities and collection of taxes.

Effective tax administration is key to ensuring that tax systems function properly and that governments can finance public goods and services. The definition by Evans (2008), like previous authors, links the concepts of tax administration, process and structure and emphasizes the role of government to impose and collect taxes. Tax administration encompasses various functions such as auditing, enforcement and taxpayer services that are designed to ensure tax compliance and maximize revenue collection. Keen (2013) also lists other functions of tax administration consisting of the implementation and enforcement of tax laws by government agencies. Additional activities are taxpayer registration, tax assessment, tax collection, and dispute resolution. The author notes that the efficiency and integrity of tax administration are crucial to the success of any tax policy.

From a legislative perspective, the tax administration is obliged to act in accordance with the law, to strictly comply with national laws and regulations, and not to violate legal provisions. Zhang (2024) in his article "Research on Tax Management and Tax Risk Prevention Measures" specifically identifies the following two principles that should guide tax administration:

- **The principle of fairness.** Treat all taxpayers equally and do not favour any party.
- **Principle of efficiency.** To focus on efficiency, minimise unnecessary waste and repetitive work and increase the effectiveness of administration. The tax administration should simplify procedures and processes as much as possible, reduce unnecessary links and procedures, and make it easier for taxpayers to deal with transactions.

Kamenická (2013) discusses the importance of tax administration and attributes to it strategic importance in the functioning of public finances and economic stability of the state, effective tax collection and the fight against tax evasion, thus contributing to the financing of public goods and services. According to the authors Tanzi and Zee (2000), they identify tax administration as a crucial actor in the overall efficiency of the tax system. It is the mechanism through which the government can enforce tax laws and ensure a fair distribution of the tax burden among its citizens. A well-functioning tax administration is essential to the credibility and legitimacy of the tax system. Globally, the views of the authors cited highlight the key role of the tax administration in enforcing tax laws and ensuring that governments can raise the necessary revenue to finance public services and maintain fiscal stability. Furthermore, attention will be paid to the legal aspects or legal framework and categorization of tax crimes.

1.2 Tax administration management and its role in the detection of tax crimes

Effective tax administration management requires a comprehensive approach to the prevention and detection of tax crimes. The term tax management is often referred to as tax administration management or tax management. The success of such management depends primarily on the effective alignment of human resources, represented by tax professionals, with technological systems and processes, in particular the tax information system. This synergy between the human and technological factors is key to achieving efficient tax collection that is both beneficial to the State and least problematic and compelling for taxpayers.

The analysis of the theoretical foundations of the tax administration management issue points to the aspects that are the most frequented.

- **Organisation and management of tax administration:** the author Víghová (2011) in her paper "Organisational aspects of tax administration reform " analyses the structure of tax authorities, their competences and internal processes necessary for the effective functioning of the institution.
- **Tax inspections and audits:** the issue of inspections and audits in the tax administration is dealt with by Hamalová et al. (2015) in the publication "Theory, Management and Organization of Public Administration", where the importance of detecting irregularities and tax fraud is emphasized.
- **Tax collection:** the topic of tax collection and procedures against tax defaulters is analysed by Burák (2019), where the importance of timely and efficient tax collection is highlighted.
- **Use of technology:** the modernisation of tax processes through technology and automation in line with the rise of ICT and the phenomenon of digitalisation. Tax digitalization brings a number of benefits to tax authorities as well as taxpayers that increase the efficiency and accuracy of tax administration. (Hidayat and Defitri, 2024)
- **Taxpayer education and support:** the issue of taxpayer education and support for tax compliance. (Hamalová et al., 2015)
- **International cooperation:** the importance of international cooperation in tax administration and the fight against tax evasion is also part of the work on public administration management, especially in the area of harmonization of rules. (Chaschina, 2024)

Tax statistical analysis is an essential tool for understanding tax trends and behaviour, involving the management of the collection, organisation, analysis and reporting of tax data. However, a key tax management issue is the economic incentive for taxpayers to reduce the valuation of assets and income in

order to minimize the tax burden. This problem is caused by two main factors: the first is a perverse incentive from the tax authorities, where taxpayers benefit from lower asset valuations in self-taxation schemes. The second factor is the difficulty of measuring accurate property valuations, with the methods and quality of valuations varying considerably across jurisdictions, such as the US property tax system. Technological and methodological improvements can help address this problem, but fair property valuation remains a challenge. (Lederman, 2020)

1.3 Detection of tax crimes

López (2017) reports that tax evasion often occurs in developing countries. Therefore, it is necessary to comply with tax regulations to prevent tax evasion. Most firms avoid paying taxes by remaining smaller, but larger firms can engage in costly tax evasion. In economies where incomes are too high, there is a trade-off between overall efficiency and tax collection. Where tax evasion is high, tax collection is low. There is therefore a need to focus on more effective measures against tax evasion. Townsend (2012) explains that tax evasion is the ultimate manifestation of conventional tax-related crimes. It signifies the most serious offence that taxpayers can commit and yet, if recognized as a tax violation, it results in a fine.

According to Evertsson (2016), from a globalisation perspective, tax evasion is considered a crime with global implications. This problem is not limited to tax evasion originating solely from corporations. Corporate tax avoidance is a phenomenon that simultaneously affects different regions and different companies, resulting in global implications due to companies avoiding precisely the tax obligations within the countries in which they operate. The free market structure opens up opportunities for tax avoidance as regions and countries seek to attract international investment by adjusting their tax rules to suit corporations. Buehn and Schneider (2012) highlight the emergence of a sequence of tax avoidance events in 38 OECD countries between 1999 and 2010. These occurrences are rooted in the shadow economy and its estimation models. With the combination of indirect taxes and self-employment as drivers of tax evasion, a consistent decline in these cases can be observed across countries between 1999 and 2010. In this time frame, the average extent of tax evasion is 3.2% of official GDP for all countries. Mexico leads the averages with 6.8%, closely followed by Turkey with 6.7%. In contrast, the US and some other countries ranked at the bottom with values as low as 0.5% or 1.3%.

Slemrod (2007) argues that no government can introduce a tax system and then simply expect taxpayers to voluntarily follow it. In reality, only a minority fulfill their tax obligations to the state, while the majority look for ways to avoid paying. Over time, the pool of conscientious taxpayers is shrinking, while the ranks of non-compliant individuals are growing, thanks to the belief that the more people avoid paying taxes, the more acceptable it is. As a result, it is becoming imperative that every citizen be held legally responsible for meeting their tax obligations, while those who do not comply and do not pay are penalised. Despite the imposition of sanctions, tax evasion remains widespread. Tax evasion is now much more frequent than in the past and this pattern is likely to continue in the future.

Stankeviciute (2018) has conducted empirical research focusing specifically on the challenge faced by the European Commission in tackling tax evasion and fraud within the European Union. The aim of the research was to assess and quantify the collective financial damage caused by tax evasion on tax revenues across the EU. The study covered a sample of 28 EU Member States in 2016 (currently comprising 27 Member States) and covered a 12-year period from 2003 to 2014. The research used a methodology based on the concept of the shadow economy to examine historical trends in tax evasion. Through hypothesis testing, the research identified specific EU countries characterised by taxpayers sensitive or insensitive to EU membership, as well as their correlation with the economic conditions of these countries and the size of their national tax rates.

The empirical findings of this investigation confirmed the European Commission's concerns about the adverse impact of tax evasion on the EU economy. These findings have subsequently provided a multifaceted quantitative basis for shaping future tax policies, facilitating informed decisions aimed at mitigating tax evasion losses both within and outside the EU.

The resources, in the form of statistics and reports, providing a deeper insight into the issue of detecting tax crimes, bring to light what methods and practices are most effective in addressing this challenge. They are relevant in that context:

- The Organisation for Economic Co-operation and Development (OECD) regularly publishes studies and reports on tax trends and fraud. The report "Tax Administration 2022" offers an overview of the practices of tax administrations in OECD countries and includes data on the

number of tax audits, fraud detected and the effectiveness of various tools to detect tax crimes. (OECD, 2023)

- Europol and OLAF reports: Europol and the European Anti-Fraud Office (OLAF) publish reports on cross-border tax fraud within the EU, such as VAT carousel fraud. These reports provide statistics on identified fraud and the extent of financial losses caused by fraud. (op.europa.eu 2023)
- The international intergovernmental organisation FATF Reports: the Financial Action Task Force (FATF) publishes reports on money laundering and terrorist financing, which are often linked to tax fraud. Their reports contain case studies and recommendations for the effective detection and prevention of financial crimes. (FATF, 2023)
- National statistics: Many of the european countries publish annual reports of their financial administrations, which include data on tax crimes detected, audits carried out and the results of the recovery of tax arrears.

2. Methods

The study provides an analytical perspective on the issue of tax crimes in the context of the effectiveness of tax administration management with the ambition to contribute to the improvement of tax discipline. Accordingly, the aim of the study is to comprehensively assess a selected set of performance indicators in the field of tax administration or the values achieved by eight regional tax offices and the Office for Selected Economic Entities based in the capital of Slovakia in the field of tax audits. By examining statistically significant differences between the efficiency indicators of the regional tax offices in the performance of tax audits, the empirical study will ultimately contribute to improving the efficiency of the main processes of financial administration. To this end, secondary data from the aggregated performance evaluation reports of tax offices with jurisdiction within the Slovak Republic were analysed for the period 2017 to 2023. Data collection involved gathering quantitative records from tax office databases that contained information on cases detected, processing efficiency and resource utilisation. Means, standard deviations, medians and ranges were calculated for each category to assess the efficiency of the tax administrations. MS Excel software was used to process the data and Statistica software was used to perform the statistical analyses.

Statistical analyses have been carried out to assess the effectiveness of these practices, taking into account organisational and legislative aspects. The methodology included descriptive analysis and non-parametric statistical tests, including Friedman's ANOVA, which was used to test the hypothesis regarding the effectiveness of tax administrations. It is used to analyze differences of dependent samples when the assumptions of normality and homogeneity of variances are not met. For this test, we will consider a significance level of 0.05. If the p-value for this test is less than or equal to the significance level, we will conclude that there are statistically significant differences between at least one pair of groups considered.

Based on the main objective of the study, the following sub-objectives were identified:

- To model and compare the evolution of selected tax control indicators over time for selected tax offices in Slovakia,
- to determine the overall effectiveness of controls and the effectiveness of VAT over-deduction controls over time for selected tax offices in Slovakia,
- to identify the existence of statistically significant differences in the values of selected tax control indicators between the years under examination.

Within the analysis we will use the following indicators (variables): *total number of controls, number of controls with findings, total number of controls of VAT over-deduction, number of controls with findings of VAT over-deduction, volume of findings from tax controls in EUR, volume of withheld VAT over-deduction in EUR.*

In addition to these, we will also analyse the indicators calculated by us. These will be:

- the overall effectiveness of controls, the effectiveness of controls without VAT over-deduction, the effectiveness of controls with VAT over-deduction, (this is the ratio of the number of controls with a finding to the total number of controls),
- the effectiveness of controls with VAT over-deduction (this is the ratio of the number of controls with VAT over-deduction with a finding to the total number of controls with VAT over-deduction).

3. Results

The study focuses on analyzing differences in selected indicators of tax audits over time. The aim is to identify how the values of these indicators have varied from year to year and what factors may have influenced their variability. This analysis will provide an overview of trends and changes in the effectiveness of tax audits over the period under review. The Friedman test will be used to test the hypothesis and a significance level of 0.05 will be considered. We present the results in tabular form, where we report the value of the test statistic denoted as $\chi 2$ and the p-value. We then display the differences using box plots. We interpret the results of seven indicators of the effectiveness of tax controls and two ratio indicators of the effectiveness of tax controls.

We first perform a comparison of the indicators for **the total number of inspections** and **the number of inspections with a finding** (boxplots 1 and 2), which show similar trends in the years under study, with significant increases in 2019 and 2020. This suggests more intense activity by tax authorities in this period. For both indicators, there were statistically significant differences between years, with the highest values concentrated in 2019 and 2020, which may indicate a focus on risk areas or increased capacity for control measures. In 2017 and 2018, as well as in the period 2021 to 2023, both indicators showed similar, more stable values. This trend may indicate a period of stabilisation or standardisation of control procedures that led to less pronounced differences in these indicators. Similar values in both indicators for these years may indicate that the intensity of controls has been relatively balanced, while fluctuations in 2019 and 2020 may be exceptional and due to external factors or changes in legislation and approach to tax controls.

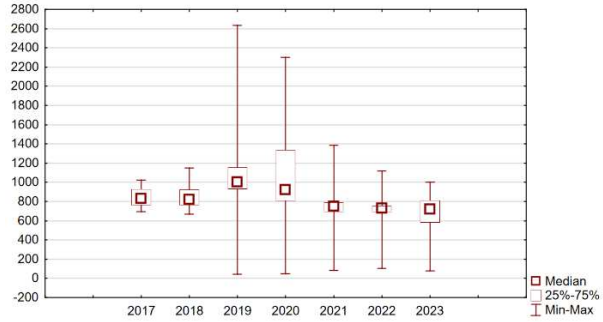

Figure 1. Total number of checks in view of the time
Source: own processing (2025)

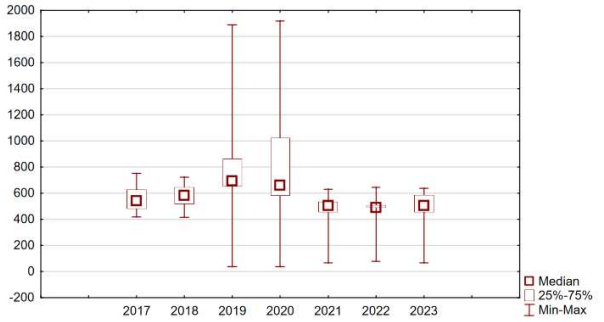

Figure 2. Number of checks with a finding
Source: own processing (2025)

The second comparison of the indicators for **the number of VAT refund inspections** and **the number of VAT refund inspections** with findings (box plots 3 and 4) reveals both similarities and differences in their development over the observed period. Both indicators show statistically significant differences across the years; however, their peak values were achieved in different years. For the number of VAT refund inspections, the highest values were recorded in 2017, indicating that tax authorities conducted more intensive inspections focused on VAT refunds during this period. In contrast, the lowest values were observed in 2022 and 2023, potentially suggesting reduced attention to this type of inspection or a strategic shift toward other areas. No significant differences were noted between 2019 and 2021, which may indicate a period of stabilization and a unified approach to these inspections. In the case of the number of VAT refund inspections with findings, the highest value occurred in 2020, possibly suggesting that inspections during this period were more targeted and effectively identified discrepancies. The lowest number of inspections with findings was in 2022, which could indicate lower inspection effectiveness or improved compliance of taxpayers with regulations. Similarly to the previous indicator, values remained stable between 2019 and 2021, supporting the notion of a consistent approach by tax authorities during this period. These differences suggest that while the overall number of VAT refund inspections was highest in 2017, the maximum effectiveness of these inspections reflected by the number of inspections with findings was achieved only in 2020. This may point to improvements in inspection methodology or targeting, which enabled a higher success rate in identifying discrepancies several years later.

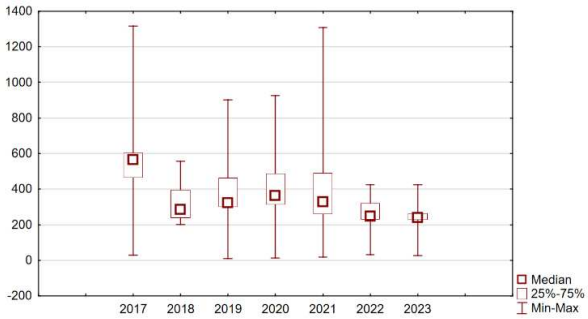

Figure 3. Number of VAT Refund Inspections
Source: own processing (2025)

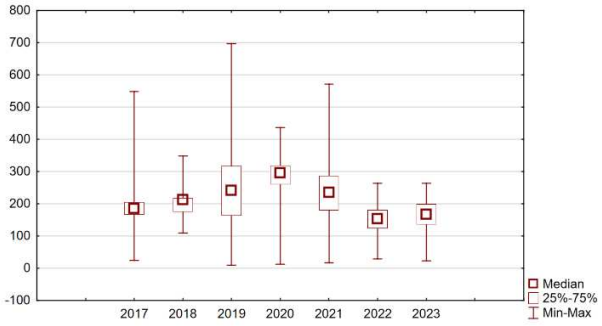

Figure 4. Number of VAT Refund Inspections with Findings
Source: own processing (2025)

The following comparison of the indicators for **the volume of findings from tax inspections** and **the volume of withheld VAT refunds** (box plots 5 and 6) reveals different trends in the development of these values over the observed years. While the volume of findings from tax inspections shows statistically significant differences between years, the volume of withheld VAT refunds remains relatively stable. For the volume of findings from tax inspections, the highest values were recorded in 2017, while the lowest were observed in 2023. This substantial decrease suggests a potential change in the approach of tax authorities to identifying discrepancies or reflects a decline in discrepancies in the observed years. Between 2018, 2020, and 2021, no significant differences were noted, which may indicate a period of relative stability in inspection procedures or less pronounced differences in the volume of findings. On the other hand, the volume of withheld VAT refunds does not exhibit significant differences between years, indicating a consistent approach by tax authorities to withholding excess VAT refunds. The stability of this indicator may signal that tax authorities maintained a similar policy for withholding VAT refunds throughout the observed period, regardless of the year. These differences suggest that while the volume of findings from tax inspections shows high variability and is sensitive to changes in approach or inspection procedures, the volume of withheld VAT refunds remains stable and less susceptible to fluctuations. This may indicate that tax authorities paid particular attention to more contentious areas with the potential for findings, while maintaining a consistent approach to withholding excess VAT refunds.

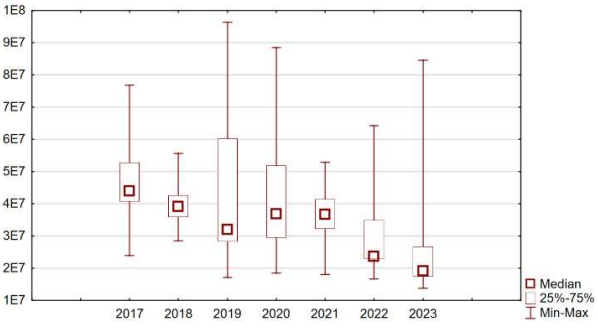

Figure 5. Volume of Findings from Tax Inspections
Source: own processing (2025)

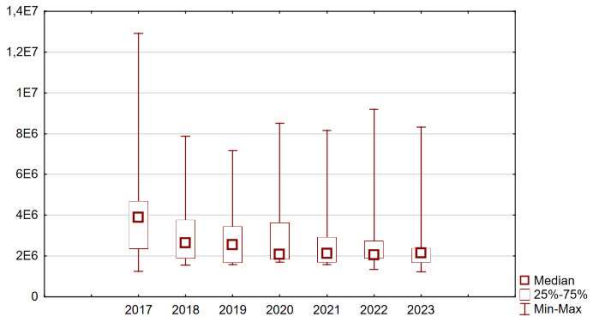

Figure 6. Volume of Withheld VAT Refunds
Source: own processing (2025)

Comparison of the indicators for **the effectiveness of inspections** and **the effectiveness of VAT refund inspections** (box plots 7 and 8) reveals differing trends in the development of these two indicators over the observed years. While inspection effectiveness shows relative stability and no statistically significant differences between years, the effectiveness of VAT refund inspections displays notable differences across periods. For inspection effectiveness, the highest performance was achieved in 2020, while the lowest was in 2018. Although no significant differences were found between years, the years 2017 and 2018 showed greater variability in inspection effectiveness, suggesting a period of adjustment or instability in inspection procedures. In later years, the inspection process stabilized, leading to reduced variation and greater consistency. In contrast, the effectiveness of VAT refund inspections showed

statistically significant differences between the observed years, with the highest effectiveness achieved in 2020, 2019, and 2018, while the lowest values were recorded in 2017 and 2021. These differences may indicate improved targeting and focus on higher-risk areas for fraud during the period from 2018 to 2020, which led to increased success in identifying discrepancies. While inspection effectiveness generally shows relative stability over time, the effectiveness of VAT refund inspections indicates a more dynamic trend, which may result from a focus on specific inspection areas and continual improvements in procedures for this type of tax obligation. This variability in the effectiveness of VAT refund inspections highlights the need for adaptability and optimization of inspection processes, which may lead to long-term improvements in the effectiveness of inspection procedures related to VAT refunds.

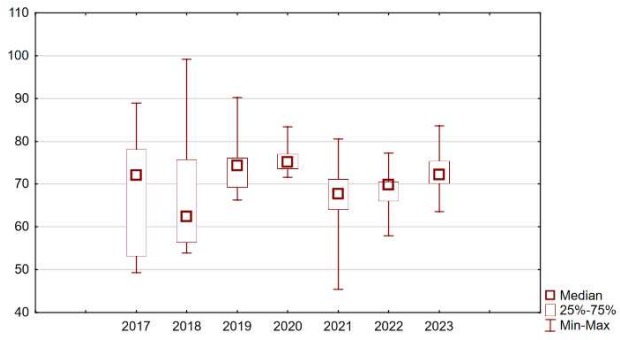

Figure 7. Overall Inspection Effectiveness
Source: own processing (2025)

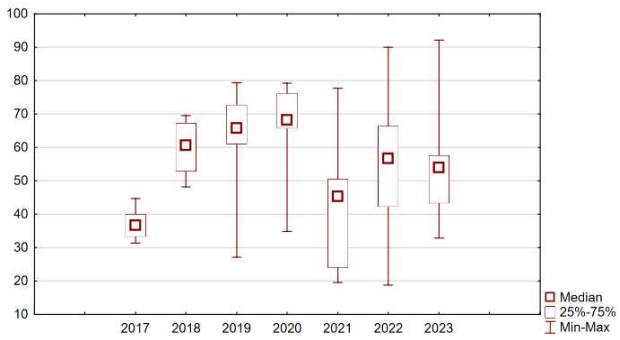

Figure 8. Effectiveness of VAT Refund Inspections
Source: own processing (2025)

Based on the provided table with chi-square (χ^2) values and p-values, the most significant statistical associations have been identified, indicating statistically significant differences between the observed indicators. The significance of the statistical association is determined by the p-value, where lower values (below the commonly used threshold of 0.05) indicate a high probability that the observed differences are statistically significant. We formulate the following hypothesis.

Research Hypothesis 1: We assume that there are statistically significant differences between the examined years regarding selected tax inspection indicators, according to data from tax authorities in Slovakia.

As shown in Table 1, the findings indicate statistically significant differences in some key indicators of tax administration, which may suggest various trends or issues in the effectiveness and focus of tax inspections over time.

Table 1. Differences Between Tax Inspection Indicators in view of the time

Indicators of Tax Inspection Efficiency	**χ^2**	**p-value**
Total Number of Inspections	19.4343	0.0035 *
Number of Inspections with Findings	22.5657	0.0010 *
Total Number of VAT Refund Inspections	17.1634	0.0087 *
Number of VAT Refund Inspections with Findings	16.8287	0.0100 *
Volume of Findings from Tax Inspections in €	21.6667	0.0014 *
Volume of Withheld VAT Refunds in €	6.8588	0.3341
Overall Inspection Efficiency	12.3810	0.0540
Efficiency of VAT Refund Inspections	19.5538	0.0033 *

Source: Gombár et al. (2025)

The results from Table 1 can be interpreted as follows. The number of inspections with findings and the volume of findings from tax inspections in € exhibit strong statistical associations, indicating that the success of inspections in identifying discrepancies and their financial volume differs significantly across periods. These differences may be due to various factors, such as an increase in inspection capacity, targeting specific sectors, or changes in inspection methodology. Such differences may suggest that

certain periods or groups of taxpayers required more intensive oversight. The efficiency of VAT refund inspections ($\chi^2 = 19.5538$, $p = 0.0033$) also shows statistical significance, indicating differences in the success of VAT refund inspections. This variability in efficiency may result from specific challenges associated with auditing refunds, which may involve case complexity or capacity constraints of tax authorities. Conversely, the volume of withheld VAT refunds in € does not show statistically significant differences ($p = 0.3341$), indicating stability in this indicator. This result may reflect a consistent approach by tax authorities to withholding excess refunds or stable volumes of such refunds over the observed period. Overall, these findings indicate dynamic trends in the effectiveness and focus of tax inspections depending on the time period and potentially on changes in legal or administrative conditions. The results suggest that improvements in specific areas could contribute to greater inspection efficiency and reduced tax evasion.

In conclusion, we state that we have achieved the objective of identifying the existence of statistically significant differences in the values of selected tax inspection indicators between the examined years. This implies that, over the observed period, the values of the indicators "*volume of withheld VAT refunds in euros*" and "*overall inspection efficiency*" do not change significantly. The research hypothesis has been confirmed.

4. Discussion

The results related to the examined tax authorities and their performance in tax inspections from 2017 to 2023 provide valuable insights into the efficiency, success rate, and focus of tax inspections. Statistical differences between the periods and indicators suggest that process improvements and optimization of inspection procedures could significantly contribute to increased efficiency and success in tax supervision. It was found that the total number of findings from VAT-focused inspections shows significant differences between the years. The highest values were achieved in 2019 and 2020, while the lowest values were observed in 2022 and 2023. This suggests that during certain periods, tax authorities focused on more efficient targeting of inspection activities or had more resources available to address VAT fraud. For practice, this means that, to maintain consistent results in VAT inspections, it would be beneficial to ensure stable resources and procedures that allow for the effective use of available capacities each year. Establishing permanent inspection standards can help avoid substantial fluctuations between years. Significant differences were also observed in the number of inspections with findings and in the volume of findings from tax inspections. Years with higher inspection volumes and success rates, such as 2017 and 2020, show that a targeted and efficient approach yields measurable results.

Based on the findings, the efficiency of tax inspections could be increased through the implementation of a risk-oriented approach, where resources are concentrated in sectors with a higher risk of tax evasion, thus maximizing the use of available resources. Utilizing advanced analytical tools, such as data analytics and machine learning algorithms, can help more accurately predict the likelihood of tax evasion and identify patterns of risky behavior. A flexible and regularly updated approach to inspection strategies will enable a quicker response to economic and legislative changes, while enhancing the expertise of tax authority staff through specialized training will improve their ability to identify risk factors and effectively use new methods of fraud detection. The effectiveness of tax inspections could also be supported by better collaboration among regional tax authorities, allowing for the exchange of information on best practices and harmonization of approaches to tax evasion detection at the national level.

We have confirmed that tax administration management plays a key role in ensuring effective tax collection and preventing tax evasion. In the context of tax crime, such as tax fraud, it is essential to introduce tools and procedures capable of responding to changes in legislation and the technological environment, contributing to more effective tax inspections. The analysis focused on the effectiveness of tax inspections with and without VAT refunds and the identification of regional differences among tax authorities in Slovakia over the period from 2017 to 2023.

Conclusion

The study provided an analytical perspective on the issue of tax crimes in the context of tax administration management efficiency. The study focused on the research objective of verifying the existence of significant differences among selected efficiency indicators of tax inspections during the monitored period within regional tax offices, based on annual reports. The existence of statistically

significant differences between the examined years for selected tax inspection indicators was verified according to data from tax authorities in Slovakia. The interpretation of the analysis results provided a foundation for formulating and proposing possible measures for tax administration management in the context of reducing tax crimes. The conducted research offered a substantial basis for further study and analysis, as it represents essential material with the potential to explore the relationship between tax administration management and the efficiency of tax inspections more deeply. The analysis of both theoretical and practical foundations confirmed the assumption that tax administration management is a key element in detecting tax crimes and ensuring fair tax collection. This research also opened up the opportunity to broaden the discussion and propose additional solutions with the potential to improve tax administration management, enhance the success rate of tax inspections, and contribute to the overall improvement of tax system functioning.

The Fluid Reality Theory of Pygmalion Effect in Management: Integrating the Consciousness Equation and Oxytocin-Mediated Trust

***Assaf* Ichilov**[1,*]

[1] Uniwersytet im. Adama Mickiewicza, Faculty of Education, Poznan, Poland

Abstract

Research Background: The Pygmalion effect demonstrates how managerial expectations can influence employee performance through self-fulfilling prophecies, yet the underlying neurobiological mechanisms remain poorly understood. Classic studies in organizational psychology show that leader expectations significantly impact subordinate performance but lack integration of neuroscientific evidence explaining how intangible expectations translate into concrete behavioral changes.
Purpose of the Article: This paper presents a unified theoretical framework integrating Fluid Reality Theory's Consciousness Equation ($\partial C/\partial t = k \cdot (I \times E - \alpha C)$) with oxytocin-mediated trust mechanisms to explain how managerial expectations shape employee performance through neurobiological and boundary dynamics. The model proposes that Connection Quality (C) represents the permeability of self-other boundaries, driven by Imagination (I) and Environment (E), with oxytocin serving as a physiological substrate mediating trust and bonding.
Methods: A theoretical synthesis approach was employed, integrating evidence from neuroscience, organizational psychology, and educational research. The analysis drew on established research on the Pygmalion effect, oxytocin's role in trust formation, and dynamic systems theory to develop the integrated framework.
Findings and Added Value: The unified model demonstrates that high managerial expectations combined with supportive environments increase Connection Quality, fostering trust, openness, and adaptive performance. Research evidence supports that oxytocin release underlies trust-building processes, with moderate challenge and social support triggering neurochemical responses that enhance focus and social connection. The framework generates testable predictions across multiple levels, from measurable brain signals to hormonal markers and improved organizational outcomes.

Keywords: Pygmalion effect, Consciousness equation, Oxytocin, Trust, Leadership expectations, Organizational neuroscience

JEL classification: E24; J50

1. Introduction

Human beings are inherently interconnected and adaptive, continuously shaped by relationships and expectations from others. Classic studies in education demonstrated the powerful Pygmalion effect: when teachers were led to hold high expectations for certain students, those students significantly improved their performance, whereas low expectations led to poorer performance (Rosenthal & Jacobson, 1968; Eden, 1990; Livingston, 1988; Eden et al., 2000). In organizational psychology, a similar phenomenon occurs—managers' beliefs about employees can become self-fulfilling prophecies that boost or hinder productivity and growth (Livingston, 2003).

Yet, the underlying mechanism by which an intangible expectation translates into concrete changes in another person's motivation, learning, or performance has remained elusive. How do a leader's or educator's mental states and assumptions come to literally change the physiological and psychological state of their followers or students? Recent advances suggest a convergence of explanations: neuroscience

[*] Corresponding author: assafichilov@gmail.com

identifies neurohormonal pathways (like oxytocin) that underlie trust, social bonding, and stress responses, while systems theory and consciousness research propose that the mind is not a static entity but a dynamic process of boundary modulation between self and environment.

The Pygmalion effect has been extensively explored in organizational contexts, with numerous studies clarifying the effect and identifying mediating mechanisms of leadership and self-expectations (Siegel, 2020; Rosenthal & Jacobson, 1968; Eden, 1990; Livingston, 1988; Eden et al., 2000; McNatt, 2000). Research demonstrates that the finding that leader expectations for subordinate performance can subconsciously affect leader behavior and subordinate performance operates through two primary mediators: leadership behavior and self-expectations (Kierein & Gold, 2000; Fishbein, 2021; Good et al., 2016). However, several factors limit the application of the Pygmalion effect to workplace settings, including its subconscious nature, ethical considerations, and questions about generalizability across different populations and contexts.

Building on this foundation, we introduce the Dynamic Boundary Theory of Expectation, which integrates Fluid Reality Theory's Consciousness Equation with the biochemistry of social bonding. Research by Zak and colleagues revealed that trust is biologically mediated by oxytocin: higher interpersonal trust correlates with surges in oxytocin, which in turn enhance empathy and cooperation (Zak, 2017). In workplace experiments, simply assigning challenging-yet-achievable goals—a sign that a manager expects high performance—triggers moderate stress that releases oxytocin, sharpening employees' focus and strengthening their social bonds as they work toward the goal.

This paper develops a unified theoretical framework combining the Consciousness Equation with oxytocin-mediated expectation models to explain how managerial expectations permeate boundaries to affect employee performance. Through interdisciplinary integration spanning cognitive science, endocrinology, and organizational psychology, we aim to provide a novel, testable explanation for expectation-driven performance that spans from systems theory to the molecular biology of trust.

2. Methods

2.1 Theoretical Synthesis Approach

This study employed a theoretical synthesis methodology to develop an integrated framework combining established theories from multiple disciplines. The approach involved systematic integration of evidence from neuroscience research on oxytocin and trust, organizational psychology literature on the Pygmalion effect, and dynamic systems theory related to consciousness and boundary processes.

The synthesis process drew on peer-reviewed research from established databases to identify convergent themes and mechanisms across different theoretical domains. Particular attention was paid to empirical studies demonstrating the neurobiological basis of trust formation, the documented effects of managerial expectations on employee performance, and evidence for dynamic boundary processes in human consciousness and social interaction.

2.2 Framework Development

The theoretical framework development involved three primary components: (1) articulation of the Consciousness Equation as a mathematical model for boundary dynamics, (2) integration of oxytocin-mediated trust mechanisms as biological substrates for social bonding, and (3) synthesis of these elements into a unified model explaining expectation-performance relationships.

The framework development process emphasized testable predictions and empirical grounding, ensuring that abstract theoretical constructs could be operationalized and measured through established research methods. Each component of the integrated model was linked to specific measurable variables and behavioral outcomes.

2.3 Evidence Integration

Evidence integration focused on identifying empirical support for key components of the unified framework from existing research. This included reviewing studies on the Pygmalion effect in organizational settings, neuroscientific research on oxytocin's role in trust and social bonding, and evidence for dynamic boundary processes in consciousness research.

The analysis emphasized convergent findings across different methodological approaches and research contexts, identifying robust patterns that support the integrated theoretical framework while acknowledging limitations and areas requiring further empirical validation.

3. Results

3.1 The Consciousness Equation and Dynamic Boundary Process

The Consciousness Equation (Fuchs et al., 2025) emerged from efforts to model consciousness as a process rather than a static entity. This framework proposes that Connection Quality (C) represents the permeability or flexibility of the boundary separating an individual's inner self from the external world. When C is high, the person is open, connected, and integrative—experiencing fluid exchange with their environment. When C is low, the boundary is rigid—the person is isolated, resistant to outside input, or constrained in perspective.

The equation $\partial C/\partial t = k \cdot (I \times E - \alpha C)$ states that the rate of change in connection quality is driven by the excess of the imagination-environment interaction over the damping (boundary-closing) force. Connection Quality changes over time ($\partial C/\partial t$) depending on two driving factors: Imagination (I), encompassing internal models, expectations, and beliefs, and Environment (E), representing external reality including social input and material conditions.

The term $I \times E$ denotes the interaction between inner and outer forces (Fuchs, 2025). For example, an employee's imagination might include their self-concept and aspirations, while the environment includes the manager's behavior, organizational climate, and workplace culture. Only when these factors interact meaningfully can growth in connection occur. The equation introduces scaling constant k, reflecting how sensitively the boundary responds to the I×E interaction, and damping coefficient α, capturing the system's tendency to stabilize or close boundaries over time.

3.2 Oxytocin-Mediated Trust Mechanisms

Oxytocin, often called the "bonding hormone," is released in the brain during positive social interactions involving trust, empathy, or moderate challenge. It lowers anxiety and fosters connection or collaboration. Research demonstrates that when managers provide supportive challenge—expressing confidence while offering appropriate difficulty—employees experience manageable stress that triggers oxytocin along with other neurochemicals (Zak, 2017).

Evidence from workplace studies shows that "when a manager assigns a team a difficult but achievable job, the moderate stress of the task releases oxytocin… which intensifies people's focus and strengthens social connections" (Zak, 2017). This oxytocin surge momentarily increases Connection Quality by biochemically reducing fear (lowering α, the boundary-closing force) and enhancing the reward of social contact (effectively boosting k, the sensitivity to the I×E interaction).

The neurobiological evidence supports oxytocin's role as a key mediator in trust formation and social bonding. Studies using intranasal oxytocin administration demonstrate causal relationships between oxytocin levels and trust behaviors in economic games, with individuals showing greater trust and cooperation when oxytocin is elevated (de Visser et al., 2016). These findings extend to automated agents, suggesting that oxytocin enhances affinity for social stimuli broadly.

3.3 Integrated Expectation-Performance Model

The unified model demonstrates how managerial expectations translate into employee performance through dynamic boundary processes mediated by oxytocin. A manager's initial expectation guides their behavior toward the employee, delivering signals and trust cues that, if positive, trigger oxytocin and trust responses. Oxytocin physiologically mediates bonding, making the employee feel safe and supported.

Consequently, the employee's internal state shifts—they develop higher self-belief and lower stress, becoming more open to challenge. This enhanced internal state enables stronger performance through greater effort, creativity, and willingness to collaborate. Improved performance feeds back into the manager's perceptions, reinforcing high expectations and completing the self-fulfilling cycle.

Mathematical representation maps these dynamics onto the Consciousness Equation framework. In the employee's perspective, their rate of change in C follows $\partial C/\partial t = k \cdot (I \times E - \alpha C)$. The manager's behaviors influence E (external input), and the employee's evolving mindset represents I. High expectation and support mean E is rich, and the employee's I grows with confidence, thus I×E is large and positive, driving C upward.

The oxytocin effect temporarily increases k (making the employee more sensitive to the experience) and decreases α (reducing the tendency to close off). As a result, C rises more quickly than it otherwise would. Over time, if this state is repeated and reinforced, the employee may reach a new stable high-C state characterized by lasting trust and higher self-efficacy.

3.4 Empirical Support Across Multiple Levels

Neuroscientific evidence supports boundary flexibility as measurable in brain function. Research demonstrates that conditions raising Connection Quality correlate with increased neural synchrony across distributed networks, particularly gamma-band oscillations associated with feature integration and conscious attention. Studies on mindfulness and unity experiences show that individuals reporting boundary dissolution exhibit unusual high-frequency coherence across cortical areas.

Recent neuroimaging research using hyperscanning techniques found that brain-to-brain synchrony increased when partners established mutual trust and shared goals, compared to low-trust conditions. This provides direct neural evidence for interpersonal connection quality as a measurable phenomenon.

Organizational research confirms expectation effects in workplace settings. Meta-analyses of leadership development programs found that Pygmalion leadership training produces some of the strongest effects among various leadership interventions (Eden et al., 2000). Studies in military settings demonstrated that instructors led to believe certain trainees had exceptional leadership potential saw those trainees outperform control groups on objective measures.

However, research also identifies important limitations and boundary conditions. The Pygmalion effect shows limited generalizability to experienced employees and established work groups, raising questions about when and how expectation effects operate most effectively (Kierein & Gold, 2000). Additionally, the subconscious nature of traditional Pygmalion manipulations creates ethical concerns about deceptive practices in organizational settings.

4. Discussion

4.1 Theoretical Contributions and Integration

This research contributes several theoretical advances that broaden understanding of expectation-performance relationships while bridging gaps between neuroscience and organizational psychology. The integration of dynamic boundary theory with neurobiological mechanisms provides a mechanistic explanation for phenomena previously described only at behavioral levels.

The unified framework addresses the fragmentation in existing scholarship by demonstrating how psychological, neurobiological, and organizational factors interact synergistically to produce expectation effects. Rather than treating individual cognition, social dynamics, and biological processes as separate domains, the model shows how these operate as interconnected systems.

The framework's multi-level structure enables empirical validation across different scales of analysis. At the neural level, Connection Quality corresponds to patterns of brain network integration; at the psychological level, to measures of openness and trust; and at the organizational level, to team cohesion and performance outcomes. This multi-level operationalization means the theory can be tested using various methodological approaches.

4.2 Mechanisms and Boundary Conditions

The model highlights feedback loops inherent in expectation effects. Connection Quality feeds on itself through the damping term α—if C grows, damping grows, creating potential equilibrium unless $I \times E$ continues rising. This self-limiting mechanism may explain why even excellent coaching must be sustained or growth plateaus.

Conversely, positive feedback via manager reactions to performance can increase both I and E further. Nonlinear dynamics, such as tipping points or rapid phase shifts, may occur when slight increases in trust push the system over a threshold where $I \times E$ consistently exceeds αC, leading to transformational improvement in relationships and performance.

The framework identifies several boundary conditions affecting expectation effects. The model predicts that individuals with higher baseline sensitivity (higher k values) will be more responsive to expectation interventions. Similarly, environments with lower baseline damping (lower α) should show stronger expectation effects. These parameters likely vary based on individual differences, organizational culture, and relationship history.

4.3 Practical Implications for Leadership

The unified framework generates specific recommendations for leadership development and organizational design. Leaders should recognize that every interaction literally changes the neurochemical

states of their employees. Trust and positive expectations have material effects on brain chemistry and performance beyond psychological influences.

Practical applications include providing both Imagination and Environment supports—encouraging employees to envision high goals while offering necessary resources and psychological safety. Simple practices like setting challenging but attainable goals while explicitly expressing confidence can trigger beneficial oxytocin-mediated responses.

The model emphasizes the importance of timing and consistency in expectation setting. Since oxytocin effects are temporary (rising within minutes, decaying over hours), sustained positive interactions are necessary to establish lasting high-trust relationships. Leaders must understand that building connection quality requires ongoing attention rather than one-time interventions.

4.4 Limitations and Future Research Directions

This theoretical synthesis has several limitations requiring attention in future research. The framework relies primarily on correlational evidence and laboratory studies rather than longitudinal field experiments in organizational settings. While individual components have empirical support, the integrated model requires systematic validation.

The focus on oxytocin may oversimplify complex neurochemical processes involved in trust and performance. Other neurotransmitters and hormones (dopamine, cortisol, norepinephrine) likely interact with oxytocin in ways not fully captured by the current model. Future research should investigate these interactions and their implications for expectation effects.

Cultural and individual differences in oxytocin responsiveness may moderate the model's predictions. Research suggests significant variation in oxytocin receptor genetics and cultural norms around trust that could affect how expectation interventions operate across different populations.

The ethical implications of deliberately manipulating neurochemical responses in organizational settings require careful consideration. While the model aims to enhance rather than exploit employee potential, leaders must ensure interventions serve employee development rather than mere performance extraction.

Future research should focus on longitudinal field studies testing the integrated model's predictions in real organizational settings. Studies should simultaneously measure variables across neural, hormonal, psychological, and performance levels to validate the proposed mechanisms. Additionally, research should explore individual and contextual moderators that influence when and how expectation effects operate most effectively.

Conclusions

This research demonstrates that the Pygmalion effect can be understood through an integrated framework combining dynamic boundary theory with neurobiological mechanisms of trust formation. The unified model shows how managerial expectations translate into employee performance through measurable changes in connection quality mediated by oxytocin and other neurochemical processes.

The framework's strength lies in its ability to bridge abstract theoretical concepts with concrete biological mechanisms, providing testable predictions across multiple levels of analysis. By grounding expectation effects in neuroscience while maintaining connection to organizational outcomes, the model offers both theoretical advancement and practical guidance for leadership development.

The integration reveals that effective leadership involves consciously creating conditions that enhance connection quality between managers and employees. This requires attention to both internal factors (employee mindset and aspirations) and environmental factors (organizational support and challenge), with neurobiological processes serving as mediating mechanisms.

Future applications of this framework could transform leadership development by incorporating neuroscientific insights into management training. Rather than treating trust and expectations as soft skills, leaders could learn to understand and influence the biological processes underlying human motivation and performance.

The ultimate goal involves creating organizational conditions where all employees can access the neurobiological and psychological states necessary for optimal performance and growth. This requires sustained commitment to relationship-based approaches that combine high expectations with genuine support, guided by scientific understanding of how human consciousness and connection operate at multiple levels.

Proactive Agility - Barriers and Capabilities of Companies: Evidence from Slovakia

Andrea **Janáková Sujová**[1,*] **and** ***Martin*** **Halász**[1]

[1] Technical University in Zvolen, Department of Economics, Business and Management, Faculty of Wood Sciences and Technology, T. G. Masaryka 24, 960 01 Zvolen, Slovakia

Abstract

Research background: The concept of proactive business agility, which represents its highest level, is a key aspect of sustainable competitiveness in today's volatile business environment. Identifying barriers and capabilities of companies to be agile is essential knowledge in building proactive agility.
Purpose of the article: The purpose of this article is to highlight the importance of proactive agility in companies, as well as the possible barriers and capabilities of companies in building it. The aim of the paper is to identify the factors influencing the development of the ability to be proactively agile and to analyze their presence in Slovak companies.
Methods: To achieve the set aim, secondary research was conducted to summarize knowledge and create a uniform interpretation, as well as primary research in Slovak companies using a questionnaire. The paper presents partial results of the questionnaire survey focused on identifying barriers and capabilities of companies to be agile. The results of the primary research were evaluated using selected statistical methods.
Findings & Value added: The results of the secondary research showed that opinions are not uniform in the examined issue. The results of empirical research in Slovak companies show that the main barriers to the development of agility are the complex bureaucracy and regulatory environment in Slovakia and the lack of workers with the necessary agile skills. Slovak managers consider flexible decision-making and responding to customer feedback to be the most important agile capabilities. The article provides a unified interpretation of proactive business agility, barriers and capabilities for developing agility in companies, and empirical findings about existing barriers and capabilities in Slovak companies.

Keywords: Proactive agility, Agility barriers, Agile capability, Slovak enterprises

JEL classification: L26, M10, O30

1. Introduction

In today's highly dynamic and turbulent business environment, the ability of organisations to respond quickly and effectively to change is becoming a critical factor for competitiveness and long-term sustainability. This capability is captured by the term agility, which refers to an organization's capacity to perceive changes in the external environment, make informed decisions, and subsequently adapt or transform its activities (Badakhshan et al., 2019; Omowole et al., 2024). Agility has emerged as a response to rigid and linear models of project and process management, such as the 'waterfall' approach. Instead of planning large, static phases, agile methods encourage iterative development, continuous user feedback, and rapid prototyping, ensuring that results remain relevant and adapted to changing needs (Mergel et al., 2020). These principles originally originated in software development, but have gradually spread to public administration (Mergel et al., 2020), healthcare (Obeidat et al., 2021) and SME management (Omowole et al., 2024). The Agile Manifesto (Beck et al., 2001) identifies four core values - individuals and interactions over processes and tools; functional software over extensive documentation; customer collaboration over contractual negotiations; and responsiveness to change over blind adherence to a plan. These values emphasize a proactive, human-centered philosophy. Thus, agility is not just a set of tools or practices, but a mind-set - a cultural and strategic approach focused on flexibility,

[*] Corresponding author: sujova@tuzvo.sk

responsiveness, and innovation (Ozkan et al., 2020). Empirical studies have shown that agile organizations exhibit greater resilience during economic shocks, better manage uncertainty, and exhibit higher levels of innovation and customer satisfaction (Omowole et al., 2024; Obeidat et al., 2021). Agility thus becomes a key enabler of organizational excellence, especially when supported by strategic capabilities such as autonomous decision making, lean management, and digital transformation (Obeidat et al., 2021; Badakhshan et al., 2019).

Within organisational development, agility can be seen as a multi-level concept, with proactive agility representing its most advanced form. In contrast to reactive agility, which focuses on responding flexibly to changes already underway, proactive agility emphasizes anticipating future challenges and managing them proactively before they occur (Werder et al., 2023). In this way, the organisation becomes not just a passive object of external influences, but an active agent that shapes its environment through the ability to anticipate, learn and adapt. Proactive agility requires strategic thinking, decentralized decision making, strong market perception and rapid deployment of innovation. This form of agility is characterized not only by flexibility, but also by intentionality and initiative, which are anchored in a culture of continuous improvement and openness to change (Sharma et al., 2017; Geyi et al., 2019). Thus, high levels of agility are not only the result of the implementation of agile processes, but also a consequence of systematically building so-called agile capabilities. These capabilities are a combination of the abilities of individuals, teams, and the entire organization to make data-driven decisions, collaborate across functions, experiment with new solutions, and respond effectively to uncertainty (Mahadevan et al., 2019). However, a significant barrier to the development of agility, and particularly its proactive form, are barriers that can be identified at the level of strategy, structure, culture and technology (Weichbroth, 2022; Lugnet et al., 2021). The most common include resistance to change, lack of trust in teams, rigid hierarchical structures, poor internal communication, or lack of leadership support and clear direction. These barriers can cause fragmented implementation of agile principles or even failure of transformation initiatives, as highlighted by well-known case studies such as the fall of Nokia due to lack of business agility (Werder et al., 2023). It is therefore essential that any successful agile transformation includes the targeted development of agile capabilities that support the spread of agility across the organisation and enable scaling (Mahadevan et al., 2019). These capabilities need to be clearly linked to the strategic priorities of the business, with a particular focus on areas such as digital proficiency, customer centricity, decision autonomy, and the ability to collaborate across departments (Geyi et al., 2019; Sharma et al., 2017). Without this foundation, agility becomes a surface-level process change, with no real impact on performance or innovation capacity.

The purpose of this article is to highlight the importance of proactive agility in companies, as well as the possible barriers and capabilities of companies in building it. The aim of the paper is to identify the factors influencing the development of the ability to be proactively agile and to analyze their presence in Slovak companies.

2. Methods

The first part of the research was a summary of scientific knowledge from secondary sources, through which the essence of proactive agility was identified and possible barriers and capabilities for the development of agility in the enterprise were identified. In this part, mainly logical methods such as: analysis synthesis, deduction, comparison, description and analogy were used.

In the second part, we focused on primary empirical research in Slovak enterprises using a questionnaire survey. The aim of the survey was to find out what attitude Slovak enterprises have towards agility, what barriers they perceive in its development and what competences are important for the development of agility. The questionnaire survey was conducted using the Google questionnaires platform in the period from January 2024 to June 2024. Our respondents were managers or owners of companies in industries and selected service sectors: accommodation, catering and transport. In total, there are 135,088 businesses in these specific industries and service sectors (Finstat 2024), from which we randomly distributed 5,327 questionnaires. The return rate of our questionnaire survey was 277 enterprises. The first part of the questionnaire focused on the identification of the research sample: enterprise size, ownership, business activity, industry and ROE indicator. The second part of the questionnaire focused on questions regarding attitudes towards agility in the enterprise: barriers and benefits of agility, factors influencing agility, and agility pins applied in enterprises. The term agility was

replaced in the questions by its description as the ability to react to unexpected changes to avoid the risk of misunderstanding the essence of the questions.

The data obtained from the questionnaire survey were evaluated using Microsoft Excel and Statistica 12. The present evaluation was preceded by the determination of the minimum size of the research sample. The following formula was used to determine it:

$$n \geq \frac{z^2 \,.\, p \,.(1-p)}{c^2} \quad (1)$$

Where "n" represents the research sample size, "z" is the critical value of the normalized normal distribution for the chosen confidence level, "p" is the estimated population size, and "c" is the margin of error (Labudova et al., 2021).

In our research, with a population size of 135,088, a minimum representative sample size of 271 respondents is required at a confidence level (z) of 90% and a margin of error (c) of 5%. Our research sample of 277 respondents is representative at the given parameters.

The evaluation of the questions of the second part of the questionnaire survey was carried out using the methods of descriptive statistics, contingency tables and testing of dependencies using the Pearson chi-square test.

3. Results

The return rate of the questionnaire was 5.22% of enterprises engaged in industries or certain service sectors. The first part was devoted to the basic identification of the research sample necessary for obtaining relevant data that allow for a more detailed analysis of the specificities of each sector. The results of the first part of the questionnaire survey are shown in Table 1.

Table 1. Basic identification of the research sample

Characteristics	**Results**			
Business activity	Manufacturing	Services		Trade
	56.03 %	43.96 %		0 %
Number of employees	0 - 9	10 - 49	50 - 249	250 +
	43.68 %	*29.96 %*	*16.25 %*	*10.11%*
Company ownership	Net domestic capital	Domestic capital prevail	Net foreign capital	Foreign capital prevail
	70.86 %	*15.47 %*	*6.47 %*	*7.19 %*

Source: authors (2024)

Table 1 shows that according to the activity, most of the respondents are engaged in manufacturing activities. According to the number of employees, small and micro enterprises are predominant, with capital tied up mainly in the domestic environment (73.64%). The identification of the research sample was complemented by an open-ended question asking in which sector the company operates. In total, there were 14 different industries: automotive; wood industry; electrical industry; chemical industry; furniture pre-industry; food industry; machinery and textile industry; transport; metallurgical industry; gastronomy: hotels, restaurants. The highest percentage share was achieved by the catering industry with 22.30%, while the lowest percentage share was achieved by the chemical industry with 2.52% and the metallurgical industry with 2.16%.

The following section will evaluate the agile advantages, barriers, capabilities and principles that influence the ability of businesses to effectively respond and anticipate change in a dynamic environment. Figure 1 presents the results of a question in which we asked respondents what advantages they see in a business's ability to respond to change and adapt in a timely manner.

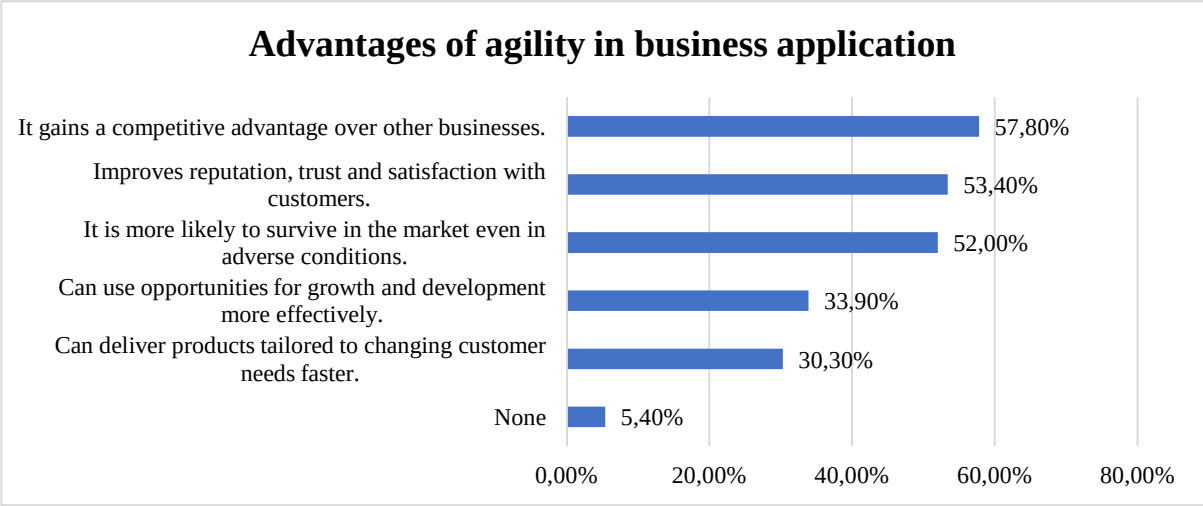

Figure 1. Advantages of agility in business application
Source: own processing (2024)

From Figure 1, we observe that the most frequently perceived benefit of applying agility in business is gaining a competitive advantage over other businesses (57.8%), followed by improved reputation, trust and customer satisfaction (53.4%) and increased ability of the business to survive in the market even in adverse conditions (52%). Fewer respondents considered the ability to more effectively exploit opportunities for growth and development (33.9%) or the ability to respond more quickly to changing customer needs (30.3%) to be an advantage. Only 5.4% of businesses did not identify any benefits associated with the application of agility.

In the next question, we asked respondents what barriers they perceived in their business' efforts to be able to react to change and adapt in a timely manner. The results are presented in Chart 2.

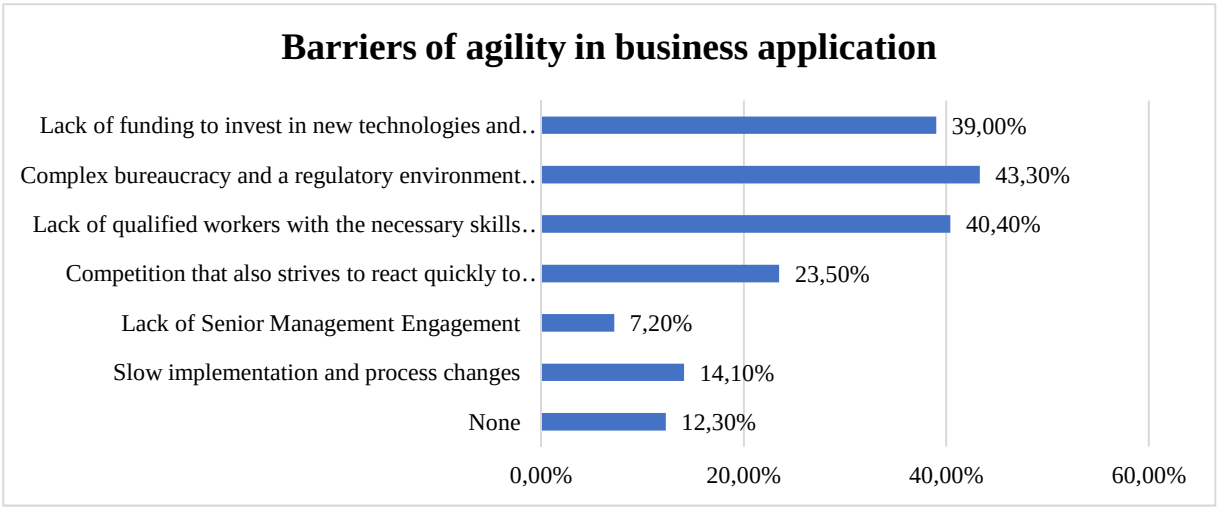

Figure 2. Barriers of agility in business application
Source: own processing (2024)

From Figure 2, we observe that the most frequently identified barrier to agility in business is complex bureaucracy and a regulatory environment that slows down decision making (43.3%). This is followed by a lack of skilled workers with the necessary skills and experience (40.4%) and a lack of funding to invest in new technologies and innovation (39.0%). Competition is also seen as a significant barrier, as it is the competition itself that reacts quickly to change (23.5%). Less common barriers are slow implementation and process changes (14.1%) and low senior management commitment (7.2%). Interestingly, 12.3% of respondents did not identify any barriers.

In the next question, we asked respondents which capabilities they consider important for the ability of the business to respond to environmental changes in a timely manner. The results are presented in Figure 3.

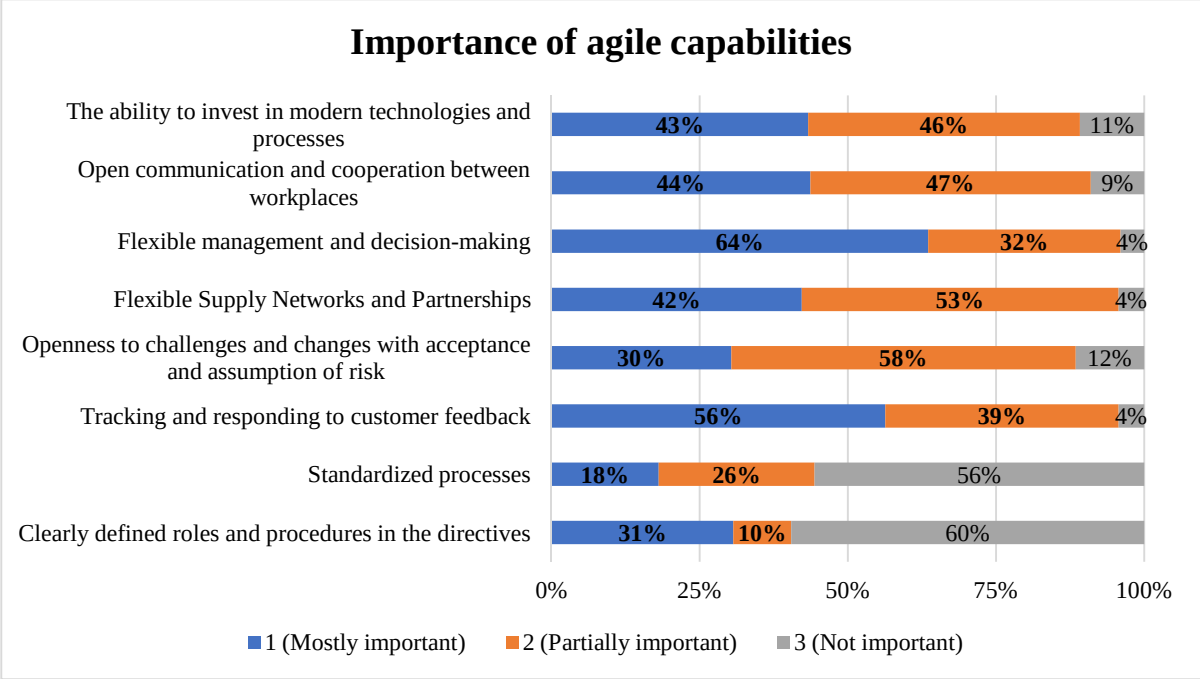

Figure 3. Importance of agile capabilities
Source: own processing (2024)

From Figure 3, we observe that respondents consider flexible management and decision making as the most important agile capability, with up to 63.54% of respondents identifying it as "very important". This is followed by the ability to monitor and respond to customer feedback (56.3%) and open communication (43.6%). Conversely, process standardization was identified as the least key capability, with only 18% of respondents considering it very important. In most cases, however, respondents combined the view of competencies as "somewhat important" and "mostly important", except for the last two options - clearly defined guidelines and procedures and standardization of processes, which are not among the agile competencies. For most of the capabilities, there is a high level of consensus on their overall importance for enterprise agility.

In the following question, we asked respondents to indicate which competencies they have in place in their company. The results of this question are presented in Figure 4.

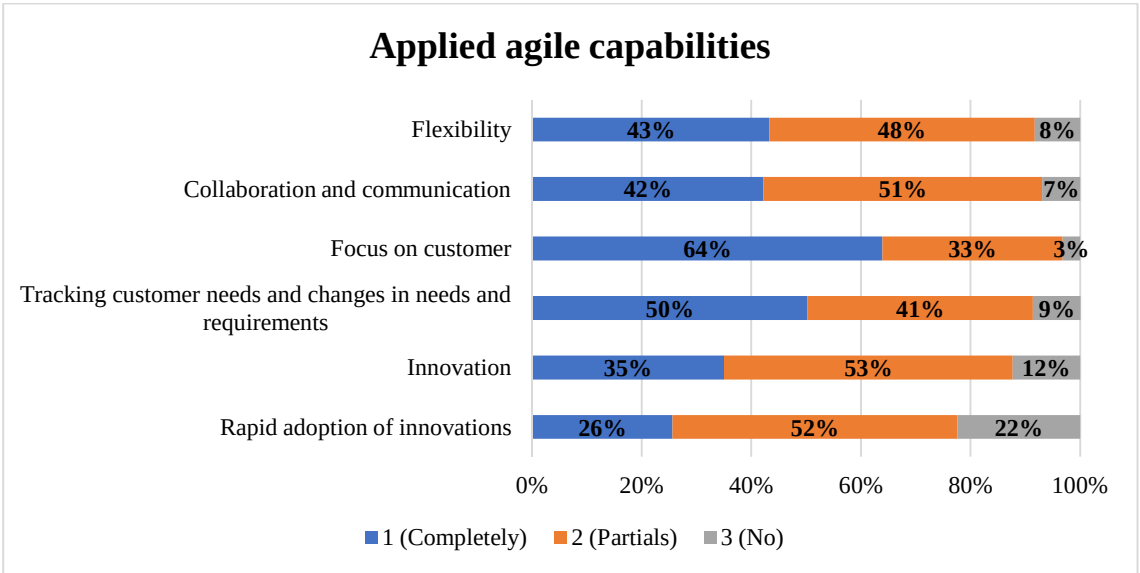

Figure 4. Applied agile capabilities
Source: own processing (2024)

From Figure 4, we observe that one of the most prevalent competencies in businesses is customer focus, which was identified as "mostly applied" by up to 63.9% of respondents. This is followed by monitoring customer needs and changes in customer requirements (50.2%) and flexibility (43.3%). A relatively high proportion of respondents also identified collaboration and communication (50.9%) and innovation (52.7%) as partially applied. Conversely, the least present capability is rapid innovation, which is mostly applied by only 25.6% of enterprises, while 22.3% said they do not have this capability at all. These results show that although basic principles such as customer orientation and flexibility are present in practice, advanced agile elements such as speed of innovation are not yet standard in the majority of Slovak enterprises.

In the last section, we compared which agile principles or capabilities the companies included in the research consider important and which are applied. The result of the findings is shown in Figure 5.

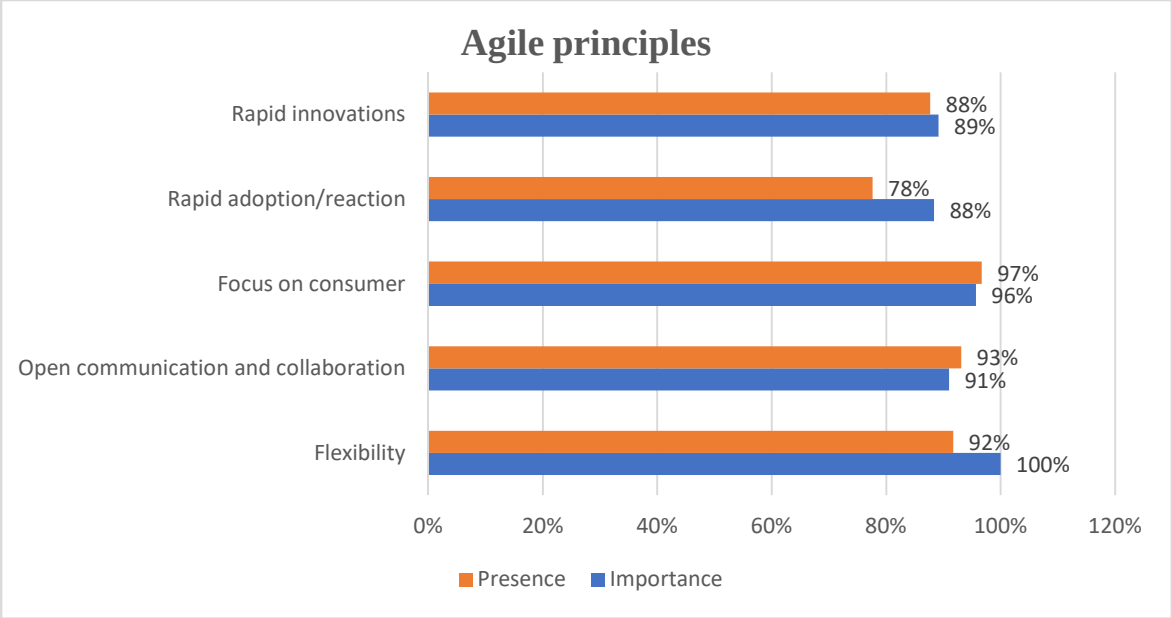

Figure 5. Agile principles – importance and application
Source: own processing (2024)

The results in Figure 5 show that the most significant difference between the perceived importance and application of agile principles is in the speed in adapting and responding to change and flexibility (8-10% difference). Given that these are the two fundamental pillars of proactive agility, there is room for improvement and focus for businesses in building agility.

4. Discussion

The results of the questionnaire survey clearly confirm that agility - especially in its proactive form - represents a key capability influencing the ability of a company to adapt to dynamic changes in the external environment. Slovak enterprises perceive agility not only as a set of tools for faster adaptation, but also as strategic thinking that can strengthen their competitiveness and long-term sustainability. The majority of respondents in our research identified gaining competitive advantage, increasing customer trust and satisfaction, and resilience in adverse market conditions as the most important benefits of an agile approach. These findings are consistent with the study of Omowole et al. (2024), which highlights agility as a key factor in the resilience of SMEs to market shocks.

In line with the findings of Geyi et al. (2019), Slovak enterprises in our survey confirm that the most important agile capabilities are flexible decision making and responsiveness to customer feedback. These capabilities enable faster organisational learning and give businesses the ability to not only embrace change but also anticipate it. This is confirmed by Werder et al. (2023), who characterize proactive agility as the highest form of agility, in which enterprises become initiators of change rather than just recipients of change. Clearly defined roles, effective internal communication or digital readiness are also important capabilities, albeit to a lesser extent.

Despite the acknowledged benefits, several barriers hinder the development of proactive agility in Slovak companies. Our data show that the most significant barriers are bureaucracy and regulatory environment and lack of skilled staff with agility knowledge. These findings are consistent with the conclusions of Weichbroth (2022) and Lugnet et al. (2021), who point out that rigid structures, lack of management support, and poor internal communication often lead to fragmented or failed agile transformation. The fact that almost a third of respondents identified the regulatory environment as a limiting factor points to the need for systemic changes, particularly in the areas of administrative simplification and innovation support.

The application of agile principles is uneven in Slovak companies. While principles such as customer orientation, flexibility and collaboration are commonly present, advanced elements - such as rapid cycles of innovation or self-organised teams - appear only rarely. This disparity suggests that even when businesses understand the importance of agility, their implementation often remains at a basic level. As Mahadevan et al. (2019) point out, true agility requires the development of capabilities at all levels of the organization - from operational processes to strategic leadership. Without this foundation, agility remains a surface change with no real impact on performance.

At the same time, our findings show that although companies declare a positive attitude towards agility, their transformation is limited by limited resources and internal resistance to change. These findings are in line with the findings of Sharma et al. (2017), who highlight that agile transformation is not only a structural change, but mainly a cultural change that requires long-term commitment, continuous learning and leadership support.

In summary, while Slovak companies understand the strategic importance of proactive agility, there is a significant implementation gap. This stems from a combination of internal (lack of skills, structural rigidity) and external (regulatory) barriers. Overcoming these requires a two-pronged approach - businesses need to develop their capabilities and internal settings in a targeted way, while policy makers should create a supportive environment for agile experimentation, innovation and talent development.

Conclusion

On the basis of the conducted research, we concluded that proactive agility plays a key role in strengthening the adaptability and competitiveness of Slovak enterprises. Although many enterprises declare a positive attitude towards agility and are aware of its strategic importance, their ability to implement proactive agility is strongly influenced by a number of internal and external barriers. Among the most significant are limited financial and human resources, rigid hierarchical structures and the complexity of the regulatory environment.

The results of the research suggest that Slovak companies most associate agility with the ability to gain a competitive advantage, increase customer satisfaction and survive even in adverse market conditions. However, advanced agile capabilities such as rapid innovation, decentralised decision-making or autonomous teams remain poorly developed in practice. This suggests that although basic agile principles are present in enterprises, their application often remains at the surface level. Another important finding is the fact that enterprises face limited external support for implementing agility and have to rely heavily on their own capabilities. This factor may contribute to slower progress in digitisation, innovation and organisational flexibility. Nevertheless, there is room for improvement, in particular through legislative changes and EU support, which can create more favourable conditions for developing agile principles and linking them to strategic business management.

A limitation of this research is the dynamic nature of the external environment, where constantly changing economic and legislative conditions can affect the ability of firms to adapt and implement effective strategies towards greater agility.

Future research should focus on the long-term impact of agility on the performance and innovation capability of Slovak enterprises, as well as on the identification of mechanisms that will enable them to overcome obstacles in the process of agile transformation. At the same time, it is recommended to focus research attention on specific forms of agile management in different sectors and size categories.

Generational Perspectives on Employee Well-being

***Terezie* Krestová**[1,*]**, *Nicola* Kubacká**[1]**, and *Marcela* Papalová**[1]

[1] VSB – Technical University of Ostrava, Department of Management, Faculty of Economics, 17. listopadu 2172/15, 708 00 Ostrava, Czechia

Abstract

Research background: In the face of rapid technological change, shifting societal structures, and evolving demands on the workforce, employee well-being has become a critical focus in contemporary human resource management. Well-being, which encompasses physical, mental and social dimensions, significantly influences both individual performance and organisational outcomes. As workplaces become increasingly multigenerational, understanding how well-being is perceived and prioritised across different age cohorts is essential for effective HR strategy development.
Purpose of the article: The primary aim of this study is to analyse differences in the perception of well-being among Generations X, Y, and Z, and to identify the factors that most significantly shape their subjective experiences of well-being. The study seeks to generate strategic insights to help organisations align HR practices with the diverse and evolving needs of employees across generational cohorts.
Methods: The research employs a mixed-methods design, with a predominant focus on quantitative analysis. Data were collected through a structured survey targeting employees of Generations X, Y, and Z. The survey assessed how participants perceive and value various aspects of well-being, including work-life balance, technological engagement, and organisational support.
Findings & Value added: The study reveals significant generational differences in expectations and experiences related to well-being. Generation Z emphasises flexibility and purpose-driven work, while Generation X favours stability and structured work environments. These findings underline the importance of generationally responsive HR policies. The paper offers practical recommendations for implementing inclusive, flexible, and development-oriented HR strategies that enhance long-term satisfaction, engagement, and motivation across the workforce.

Keywords: Employee well-being, Generational differences, Human resource management, Work-life balance, Organisational strategy

JEL classification: J24, M54, I 31

1. Introduction

In today's world, where rapid technological change, increasing demands on workers, and shifting social structures shape daily life, the topic of well-being is becoming ever more significant. Well-being, understood as a state of physical, mental, and social health, is a crucial factor that influences not only the quality of personal life but also the performance of an individual on the job.

The traditional concept of striving for a balance between work and personal life is increasingly being replaced by a contemporary approach focused on fostering well-being. This modern perspective stems from the understanding that work and family life are not separate spheres, but interconnected dimensions that together form the fabric of daily life. The key lies in creating conditions that allow for individually optimal arrangements - ones that reflect the needs, circumstances, and values of each person (Kelliher et al., 2018; Homfray et al., 2022).

In recent decades, the concept of well-being has emerged as a central theme in public health, social policy, and sustainable development. Well-being, as an overall state of contentment and fulfilment, marks a shift away from purely economic indicators such as GDP, towards a more holistic understanding of human development. The World Health Organisation (WHO) regards well-being as a key indicator of

[*] Corresponding author: terezie.krestova@vsb.cz

both quality of life and social sustainability. Its importance was underscored by the COVID-19 pandemic, which exposed the fragility of healthcare systems and the consequences of social inequalities (World Health Statistics, 2024).

Although the harmonisation of work and private life has traditionally been viewed as a personal concern, it is increasingly being integrated into human resource management as a vital element in the modernisation of workplace environments and the promotion of employee well-being (Homfray et al., 2022).

Studies using cross-sectional and longitudinal surveys in various regions indicate that perceptions of well-being vary significantly among Generations X (1965–1980), Y (1981-1999) and Z (2000–2013). Organisational well-being demonstrates a generational gradient, generally declining from Baby Boomers to Generation Z. Each generational cohort exhibits distinct patterns in terms of engagement, types of commitment, and the factors that drive workplace satisfaction (Smaliukienė and Bekešienė, 2020; Kalpesh and Nayak, 2024).

The primary aim of this study is to analyse differences in the perception of well-being among Generations X, Y, and Z, and to identify the factors that most significantly shape their subjective experiences of well-being. The study seeks to generate strategic insights to help organisations align HR practices with the diverse and evolving needs of employees across generational cohorts.

1.1 Theoretical Background

The World Health Organisation (WHO, 2021) defines well-being as a dynamic state in which both individuals and societies achieve a balance between the physical, mental, and social dimensions of life. Simons and Baldwin (2021) describe well-being as a state of positive feelings and the realisation of a person's full potential within the world. It can be assessed both subjectively and objectively through a health promotion-oriented approach.

Understandings of well-being vary significantly across cultures and contexts. While Western frameworks often emphasise individual satisfaction and subjective happiness, other traditions, such as the Latin American concept of Buen Vivir, place collective well-being and harmony with nature at the forefront (Artaraz et al., 2021). Within the scope of sustainable development, well-being is increasingly viewed as the intersection of health, social justice, and environmental sustainability, forming a foundation for new strategies in policy making and organisational governance (WHO, 2021).).

At the same time, it is becoming evident that achieving this balance is not a universal process but rather an individual journey influenced by a range of internal and external factors. These factors include not only an individual's biological and psychological predispositions, but also the social environment, available resources, and the extent to which organisations or societies create conditions conducive to supporting this balance (Lee et al., 2021).

Organisations capable of recognising and accommodating these differences, such as offering flexible working arrangements tailored to the abilities and availability of employees, hold the potential to attract a broader spectrum of talent. In doing so, they not only expand their human resource base, but also enhance the quality and diversity of skills within their teams. The outcome is a synergistic effect, whereby collaboration between employers, employees, and the wider society generates value that extends beyond conventional expectations (Homfray et al., 2022; Howard et al., 2017).

1.2 Objective and Subjective Well-being

Objective well-being focusses on measurable factors that influence quality of life, such as life expectancy, access to healthcare, education, or economic stability (World Health Statistics, 2024). Data from HR analytics and productivity metrics are also used in this context (De Neve and Ward, 2023). These indicators offer valuable information on the overall condition of society and help identify areas that require targeted improvement.

Subjective well-being, on the other hand, reflects how individuals perceive their own life circumstances, encompassing aspects such as happiness, overall life satisfaction, and emotional stability. This approach highlights the importance of social relationships, work conditions, and the ability to manage stress effectively. Research shows that higher levels of subjective well-being improve the resilience of individuals and their ability to cope with demanding challenges (World Health Statistics, 2024). Subjective well-being is typically measured using surveys and questionnaires designed to capture personal experiences and perceptions (Diener et al., 2018).

However, subjective well-being is also shaped by broader contextual factors, such as the quality of political systems. Studies by Orviska et al. (2012) show that the well-being of individuals is positively influenced by political systems that offer a high degree of democratic freedoms, effective governance, and low levels of corruption. Countries where people have better access to public services and can actively participate in decision-making processes tend to exhibit higher levels of life satisfaction.

1.3 Pillars of Well-being

O'Reilly (2013) classified the following pillars of well-being within the context of social work:

- Building meaningful relationships with partners, family, friends, colleagues, and the wider community is vital, particularly in times of stress.
- Being mentally and physically active and having a sense of purpose - through work, caregiving or personal interests - provide the direction and fulfilment of life.
- Continual learning and the commitment to human values help people, including social workers, find meaning and improve their practice.
- Giving to others through compassion, empathy, and support, whether in the form of time, care, or material resources, strengthens individuals and contributes to the well-being of society.
- Practice of mindfulness and presence supports the development of authentic relationships, effective communication, and reflective listening, all of which are foundational to the values and principles of social work.

Another multidimensional approach is represented by the PERMA model (Positive emotion, Engagement, positive Relationships, Meaning, and Accomplishment) developed by Seligman (2017). Drawing on further literature (Kalpesh and Nayak, 2024; O'Leary and Tsui, 2023; Pietruszyńska, 2023) and insights from experts at the Gallup Institute, well-being can also be understood through five core pillars that reflect key domains of human life: meaning, relationships, health, finances, and community. Based on data collected from individuals in more than 150 countries, it has been concluded that these five factors are decisive in determining whether a person is truly thriving or merely surviving. This concept formed the basis for the survey conducted in this study (Brixová, 2019), who defines these factors:

- Meaning – Focusses on a sense of purpose and fulfilment in life. Individuals who experience meaning in their activities and life goals tend to report greater happiness and greater resilience to stress.
- Relationships – Encompass the quality of interpersonal connections. People with strong and supportive relationships manage stress more effectively and generally report greater life satisfaction.
- Finances – Reflect perceptions of economic stability. Financial insecurity is a major stressor that can significantly affect quality of life.
- Health – Includes both the care of physical health and illness prevention. Sufficient physical activity, a nutritious diet, and restorative sleep are key to achieving long-term health and well-being.
- Community – Relates to one's connection with the surrounding environment and involvement in community life. Those who actively contribute to the improvement of their local context tend to experience a greater sense of fulfilment and satisfaction.

2. Methods

For this investigation, a quantitative data collection method was selected in the form of a survey. The aim of data collection was to analyse generational differences in perception of well-being and to identify the factors that influence these differences. The study focused on measuring respondents' subjective levels of well-being using standardised scales, as well as identifying relationships between generation, employment status, lifestyle, and other socio-economic factors.

The questionnaire was designed to include general demographic questions and specific items aimed at assessing various dimensions of well-being. To evaluate well-being, the questionnaire was based on the Gallup methodology as adapted by Brixová (2019). The full questionnaire is provided in Appendix 1.

The first part of the questionnaire included questions that allowed the categorisation of the respondents into their respective generational groups (Generation X, Y, or Z), as well as the collection of basic socioeconomic data such as gender, level of education, and occupational status. The second part comprised a total of 22 scaled questions divided into five main domains: physical health, mental health, social well-being, spiritual well-being, and financial well-being. Each of these areas was represented by several items intended to assess subjective perceptions of well-being within the respective domain.

The survey used closed-ended questions with a five-point Likert scale, allowing quantification of responses and subsequent statistical analysis. The Likert scale served as the primary instrument for measuring well-being, allowing respondents to express the degree to which they agreed with specific statements. The scale ranged from 1 (strongly disagree) to 5 (strongly agree), ensuring consistent evaluation in the various aspects of well-being.

The research sample consisted of 260 respondents in total. In constructing the sample, efforts were made to ensure balanced representation of the three generational cohorts (X, Y, and Z), as well as gender, in order to produce relevant and generalisable results for analysing intergenerational differences in the perception of well-being. Data collection was carried out using an online questionnaire, which enabled access to a broad spectrum of participants with diverse socioeconomic backgrounds.

The questionnaire was created using Google Forms and was distributed primarily through social media platforms and personal networks. Data collection took place in January 2025.

In line with the research objective, the following research questions were formulated:

1. Are there statistically significant differences in the perception of well-being between generations?
2. Which factors most significantly influence the level of well-being within each generational group?
3. Can a generation be identified that exhibits the highest or lowest levels of well-being?

To test for statistically significant differences in the perception of individual dimensions of subjective well-being across Generations X, Y, and Z, a one-way analysis of variance (ANOVA) was performed. This method was chosen because of its effectiveness in identifying differences in mean values among more than two groups across various quantitative variables. ANOVA was performed separately for each of the five dimensions of well-being: physical, mental, social, spiritual, and financial health.

3. Results

For analysis purposes, 7 responses were excluded from the total sample of 260 respondents, as they did not meet the criteria of the selected research sample. Consequently, 253 valid responses were analysed.

The structure of the sample in terms of gender and generational distribution is presented in Table 1.

Table 1. Sample Structure by Gender and Generation

Gender	**Men**		**Women**	
Generation	Absolute Frequency	Relative Frequency	Absolute Frequency	Relative Frequency
Z (2000–2013)	42	44.21 %	71	44.94 %
Y (1981-1999)	24	25.26 %	51	32.28 %
X (1965-1980)	29	30.53 %	36	22.78 %
Total	**95**	**37.55 %**	**158**	**62.45 %**

Source: own elaboration

To support the objectives of this article, only summary results are presented for the entire questionnaire - in the five well-being categories.

Each dimension of subjective well-being was quantified as the arithmetic mean of responses to a set of relevant items, all measured using a five-point Likert scale. The average score for each dimension was calculated as the mean of all subitems within the given category. These results are displayed in Table 2.

Table 2. Mean Scores for Well-being Dimensions by Generation

Generation	Physical Health	Mental Health	Social Well-Being	Spiritual Well-Being	Financial Well-Being
Z (2000–2013)	3.25	3.31	3.56	3.70	3.26
Y (1981-1999)	3.54	3.69	3.77	3.95	3.44
X (1965-1980)	3.46	3.89	3.78	3.96	3.34

Source: own elaboration

3.1 ANOVA Test Procedure

The independent variable under observation was generational affiliation, categorised into three levels: Generation X, Generation Y, and Generation Z. For each dimension of subjective well-being, a test was conducted to determine whether the mean scores differed statistically significantly across these generational groups.

Within the one-way analysis of variance (ANOVA), both between-group variance (variability between generations) and within-group variance (variability within each generational cohort) were calculated. The resulting F-test was used to assess whether the ratio of these variances was sufficiently large to reject the null hypothesis of equal means.

The level of statistical significance was set at $\alpha = 0.05$. Where the analysis yielded statistically significant results, Tukey's HSD post-hoc tests were applied to compare all possible pairs of groups and to identify specific intergenerational differences.

The results of the ANOVA and post-hoc analyses are summarised in Table 3.

Table 3. Summary of ANOVA Results and η^2

Dimension of Well-being	**F (2, 250)**	**p-value**	**η^2**	**Effect Size Interpretation**
Physical health	2.30	0.103	0.018	Small to medium
Psychological health	5.29	0.006	0.041	Small to medium
Social health	0.77	0.464	0.006	Negligible
Spiritual health	10.11	< 0.001	0.075	Medium or greater
Financial health	10.90	< 0.001	0.080	Medium or greater

Source: own elaboration

The one-way analysis of variance (ANOVA) indicated statistically significant generational differences in three dimensions: psychological, spiritual, and financial well-being. The corresponding effect sizes suggest a medium magnitude, highlighting the substantive relevance of generational membership in the perception of these well-being aspects.

Although the difference in physical health among groups did not reach statistical significance, the size of the effect size ($\eta^2 = 0.018$) suggests a weak effect, which could reflect a trend in generational differences in perceived physical well-being. In contrast, social health exhibited neither statistically nor practically significant differences, indicating a relatively homogeneous perception of social relationships across the generations under study.

Based on the statistically significant findings from the one-way ANOVA, post-hoc comparisons using Tukey's HSD test were conducted for the dimensions where significant generational differences were identified (psychological, spiritual, and financial health). This procedure enabled the identification of specific generational pairings with the most pronounced differences, while also controlling for multiple comparisons and thereby reducing the risk of Type I error.

Post-hoc results revealed a statistically significant difference in psychological health between Generation X and Generation Z, with a mean difference of -0.4061 ($p = 0.0086$), indicating that Generation Z reports lower levels of psychological well-being compared to Generation X. A detailed summary of these findings is presented in Table 4.

Table 4. Post-hoc Test – Psychological Health

Generation (1)	Generation (2)	Mean Difference	p-value	Statistically Significant
X	Y	-0.1036	0.7636	No
X	Z	-0.4061	0.0086	Yes
Y	Z	-0.3025	0.054	No

Source: own elaboration

In the domain of spiritual health, statistically significant differences were observed between Generation X and Generation Z (mean difference = -0.6162; p = 0.0002), as well as between Generation Y and Generation Z (mean difference = -0.4806; p = 0.0030). These findings are summarised in Table 5.

Table 5. Post-hoc Test – Spiritual Health

Generation (1)	Generation (2)	Mean Difference	p-value	Statistically Significant
X	Y	-0.1356	0.6889	No
X	Z	-0.6162	0.0002	Yes
Y	Z	-0.4806	0.0030	Yes

Source: own elaboration

In the financial health dimension, statistically significant differences were found between Generation X and Generation Z (mean difference = -0.5714; p = 0.0007), as well as between Generation Y and Generation Z (mean difference = -0.5937; p = 0.0002). These data confirm that perceived financial well-being is markedly lower among younger respondents. The corresponding results are presented in Table 6.

Table 6. Post-hoc Test – Financial Health

Generation (1)	Generation (2)	Mean Difference	p-value	Statistically Significant
X	Y	0.0223	0.9903	No
X	Z	-0.5714	0.0007	Yes
Y	Z	-0.5937	0.0002	Yes

Source: own elaboration

3.2 Responses to the Research Questions

Based on the analysis of data obtained through the quantitative survey, it was confirmed that subjective well-being perception differs statistically significantly among Generations X, Y, and Z. ***This finding clearly addresses the first research question*** (Are there statistically significant differences in the perception of well-being between generations?) significant differences were identified primarily in the dimensions of psychological, spiritual, and financial health, where Generation Z consistently reported lower levels of subjective well-being compared to older generations. These differences were substantiated through the results of the one-way ANOVA and subsequent post-hoc tests, which demonstrated that Generation Z tends to evaluate aspects such as life stability, financial security, and existential meaning significantly more negatively.

In relation to the second research question (Which factors most strongly influence the level of well-being within each generational group?) the data revealed key determinants of well-being unique to each generation. For Generation Z, the most influential factors include financial insecurity, difficulties managing stress, and weaker anchoring in a stable value system. Members of this cohort also face increased instability in both the educational and occupational spheres. For Generation Y, the level of subjective well-being is most affected by the ability to balance work and personal life, opportunities for self-fulfilment, and access to career advancement. In the case of Generation X, decisive factors include a stable working environment, health-related security, and a long-term sense of purpose in one's professional life, all of which contribute positively to their overall perception of well-being.

Addressing the third research question (Can a generation be identified that exhibits the highest or lowest level of well-being?) the analysis of mean scores across the individual well-being dimensions indicates that Generation X demonstrates the highest level of subjective well-being, particularly in the domains of

psychological and spiritual health. On the contrary, Generation Z consistently shows the lowest levels of subjective well-being in the observed areas, with the most pronounced deficits found in emotional balance, existential grounding, and perceptions of economic self-sufficiency. Generation Y generally falls between these two groups, characterised by a relatively balanced but more variable perception of life satisfaction.

4. Discussion

Generational differences in work-related attitudes are reflected in distinct patterns of organisational well-being. Research in various sectors indicates that Baby Boomers consistently report higher levels of work engagement, job satisfaction, and affective organisational commitment, in addition to lower levels of overcommitment and occupational stress (Stevanin et al., 2018).). Generation X employees typically exhibit intermediate levels of well-being, while Millennials (Generation Y) tend to report reduced engagement and elevated levels of burnout. Their organisational commitment is often more normative than affective in nature. In the limited number of studies that include Generation Z, this cohort consistently demonstrates the lowest levels of organisational engagement, with social relationships emerging as the principal determinant of their workplace well-being (Smaliukienė & Bekėsienė, 2020).

The findings of Kalpesh and Nayak (2024), based on a sample of more than 12,000 participants and using various measurement tools, support a consistent trend: while job satisfaction remains a shared concern across generations, the balance between external conditions and social influences on well-being varies significantly by generational group.

Although the current survey was conducted exclusively among Czech employees and included only three generational cohorts, the results align with the findings reported by researchers in other international contexts. Therefore, these generational differences must be carefully considered in the development of organisational and human resource strategies, particularly in areas such as staff participation, retention, and well-being support.

Conclusion

In light of current challenges in human resource management, the concept of well-being is emerging as a key strategic tool for improving working conditions, productivity, and overall employee satisfaction. This paper has presented the concept of well-being and its core pillars. With three generations currently co-existing in the labour market, creating policies that accommodate the needs and expectations of all age groups represents a significant challenge for managers.

The primary aim of this study was to analyse generational differences in the perception of well-being among Generations X, Y, and Z, and to identify the key factors that most strongly shape their subjective experiences of well-being. The research sought to provide strategic insights to support organisations in aligning their HR practices with the evolving and diverse needs of employees across generational cohorts.

Statistical analyses confirmed the presence of significant generational differences in perception of well-being, particularly in the dimensions of psychological, spiritual, and financial health. The findings indicate that Generation X reports the highest and most stable levels of subjective well-being, while Generation Z consistently displays the lowest levels. This corresponds to data indicating lower scores among Generation Z in areas such as financial security, existential grounding, and the ability to manage psychological stress. Generation Y occupies an intermediate position, characterised by a relatively balanced, yet more variable, perception of individual well-being components.

The results underscore that perceptions of well-being are not uniform across generations but are shaped by a complex interplay of biological, social, economic, and value-based factors, reflecting both the current stage of life and the broader cultural and societal context. Accordingly, it is essential that human resource management strategies account for the specific needs of each generation, offering tools that are adapted to their distinct values and life circumstances.

The findings presented in this study provide a robust empirical foundation for the design and implementation of age-sensitive HR strategies, enabling organisations to respond effectively to the needs of a heterogeneous workforce. The practical implications are particularly relevant in the areas of age management, employee well-being support, career development, and prevention of psychological burnout.

Abstract

Research background. Intangible resources, including information and intellectual components, are becoming increasingly important in digitalizing business activity. Improving the methodologies for assessing these resources is important for effective management decision-making. However, identifying and assessing intangible resources, especially digital assets, requires further improvement. Currently, no generally accepted methodologies for assessing resources that are not recognized as assets and are absent from financial statements, such as information resources, internally created business reputation, and employee training

Purpose of the articleis to develop and improve existing approaches to the assessment and identification of intangible resources in general, and digital assets in particular, as well as to develop accounting and analytical support for the use of information and intellectual resources in the business processes of the enterprise.

Methods: The study employs conceptual and system analysis, monographic and comparative analysis, statistical methods, and visualization tools. Based on publicly available statistical reporting data on the activities of Ukrainian enterprises for the period 2018-2024, correlation and regression modeling of the dependence of the enterprise's residual income indicator on the structure of capital investments was carried out.

Findings & Value added: The developed approach to the assessment and identification of intangible resources contributes to the enhancement of both the processes of managing the information and intellectual component of capital and the formation of accounting and analytical support for assessing the market value of an enterprise as a business unit.

Keywords: Recognized intangibles, Unrecognized intangibles, Digital assets, Smart contracts, Cryptocurrencies

1. Introduction

The accelerated development of information technologies, the rapid digitalization of business processes, and the introduction of artificial intelligence into the activities of economic entities are driving

* Corresponding author svitlana.lab@gmail.com

the transition of the economic systems of leading countries from Industry 4.0 to the fifth and sixth technological paradigms.

Intangible resources encompass research and development (R&D), intellectual property, brands, software, databases, structural organizational capabilities, business experience, and the professional skills of personnel. These resources are crucial for modern business units seeking to maintain competitiveness and drive innovation in an increasingly dynamic and knowledge-based economy to remain competitive and innovative.

According to a study by Brand Finance, in 2023, the global intangible value increased by 8% compared to 2022, amounting to $ 61.9 trillion, which is nearly three times higher than the US GDP (Brand Finance, 2024). During the same period, the value of global tangible net assets remains stable (62.7 trillion US dollars in 2023 compared to 62.9 trillion US dollars in 2022). In 2024, the global value of intangible assets reached USD 79.4 trillion. During the same period, the value of global tangible net assets also increased, amounting to USD 68.8 trillion. The constant increase in the value of intangible assets, as illustrated in Fig. 1 and, Fig. 2, which has been observed since 2000, reflects their growing impact on the global economy.

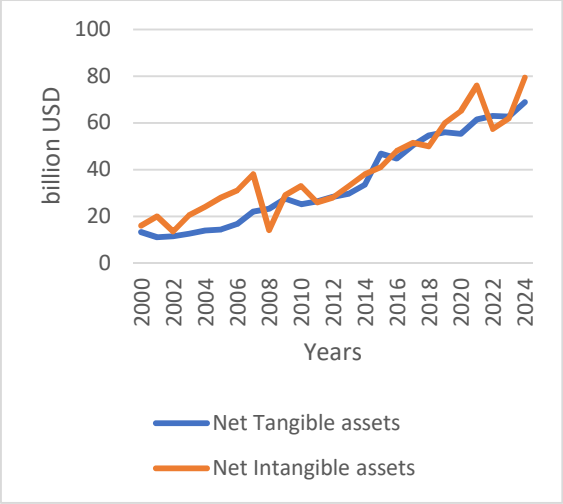

Figure 1. Dynamics of global asset value by years

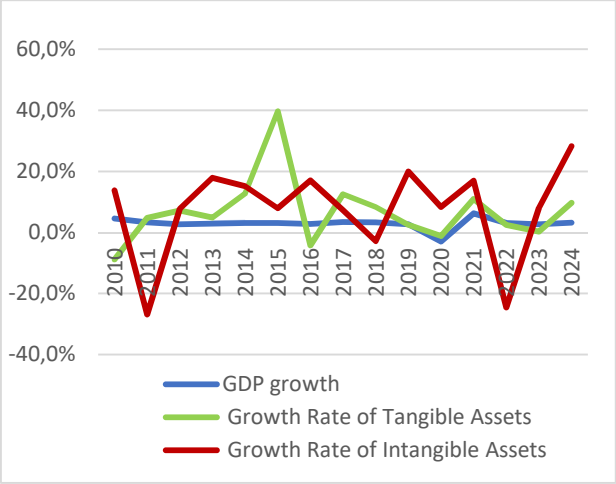

Figure 2. Dynamics of growth of global GDP and assets, %

Source: own processing (2025) *based on Brand Finance, 2024, and MacroTrends (2024)*

According to experts from Brand Finance and WIPO (Brown, A. et al., 2025), the global value of companies' intangible assets demonstrated an increase by 28% in 2024 compared to 2023, reaching its highest level since the beginning of observation. It is worth noting that countries It is worth noting characterized by a high technological structure have a high level of use of intangible assets in business processes.

The financial reports of the largest US corporations for 2024 show that, as in 2023, the predominant share of total business unit value is attributable to intangible assets (77%), compared to an average of 54% among the world's largest corporations. In contrast to the US, the Chinese economy remains largely tangible, and only 16% of the total valuation of business sector assets is valued as intangible. (Brandirectory, 2024)

A comprehensive analysis of the structure of intangible assets of the world's 500 largest corporations, conducted using data from Brand Finance, 2024, reveals a noticeable transformation in the composition of disclosed intangible value. In particular, there has been a discernible shift away from the generic category of goodwill towards more clearly defined intangible assets, such as corporate brands, proprietary software, and advanced technological solutions (Brown, A. et al., 2025). The same opinion is shared by Hayashishita, & Oda (2025), who emphasize that to respond effectively to dynamic market conditions, companies must develop the capabilities necessary to generate new knowledge. In this context, the knowledge acquisition process is closely related to investments in intellectual and information resources that form the enterprise's general intellectual property.

The results of research by Lin & Ye (2024), Glova et al. (2018) and Kiseľáková et al. (2024) demonstrate the significant impact of investments in R&D on the overall financial results of activities both at the level of individual business entities and at the level of industries, as well as on GDP growth at the level of national economic systems.

1.1 Issues in identifying and valuing intangible resources for effective management

Based on the commonly accepted understanding, intangible resources encompass both "disclosed" (i.e., reflected in the accounting and financial statements of enterprises) and "undisclosed" assets. In a general sense, "undisclosed assets" cannot be recognized as assets in accounting because they do not meet the characteristics of assets under IFRS. According to experts from Brand Finance and WIPO, such resources can be categorized into three main components: rights, relationships, and intellectual property (Brown et al., 2025).

By the recommendations of the International Accounting Standards Board, a resource is recognized as an enterprise asset if it provides future economic benefits, can be identified, is reliably measured, and is separated from the owner (enterprise). Thus, many objects of managerial influence that form the intellectual property of the enterprise remain beyond the attention of managers. At the same time, the intellectual property of the enterprise, including production experience, professional skills, business knowledge, marketing strategies, and others, often forms the enterprise's competitive advantages. Research by Stavytskyy et al.(2019), Kiseláková et al. (2024), and Gumbau-Albert &Maudos (2022) revealed a general positive impact of intangible asset growth on enterprise development. Intangible resources are generally defined as drivers of economic development for business units, industries, and national economies (Andersson et al., 2023; Sveikauskas, 2024; Labunska et al., 2024).

It should be noted that for companies, some of the intangible resources that cannot be identified as assets, primarily information and intellectual resources that generate novel knowledge, are often more valuable than identifiable intangible assets. These resources directly contribute to the formation of internally generated goodwill, which reflects the difference between the fair market value of the enterprise and the value of its identifiable tangible and intangible assets (Corrado et al., 2022; Labunska et al., 2024; Kostarakos et al., 2024).

According to the current International Financial Reporting Standards (IFRS) (IFRS Foundation, 2024), internally generated intangible resources- including information and intellectual resources- are generally not to be recognized on a company's balance sheet. According to IAS 38 Intangible Assets, certain intangible resources should be recognized as assets only if they have been acquired, or there is certainty that they will acquire, a marketable form. While research activities often do not yield direct financial benefits, they contribute significantly to the formation of internally generated goodwill within the enterprise, which arises from the acquisition of new information, knowledge, and experience during the research process (Lin & Ye, 2024). Thus, the majority of R&D expenditures are not capitalized and are considered expenses of the enterprise in the period of their incurrence. Thus, such an approach not only distorts the financial reporting of the current period and leads to incorrect assessments and misinterpretations of financial indicators, as well as the adoption of management decisions based on them, but also ignores the internally generated goodwill of the business unit.

Inaccurate assessment of intangible resources as objects of managerial influence within an economic system at any level can lead to several adverse consequences, such as underestimation of innovative potential and innovation capacity, irrational allocation of resources in business processes, and a decrease in the competitiveness and market value of the entities.

Therefore, a well-founded accounting and analytical support for the management of intangible resources, both in capitalized and non-capitalized form, plays a pivotal role in identifying drivers of economic growth at enterprises, industries, and national economic systems in general. This contributes to the development of an effective strategy and an adequate policy for managing enterprise development.

Despite their critical role in fostering innovation and enhancing competitiveness, the understanding of the composition of intangible assets remains limited.

1.2 Digital assets as objects of managerial influence

Revolutionary advancements in the implementation of modern technologies and the acceleration of business digitalization across all sectors of the economy, especially through the use of artificial intelligence and blockchain technologies in the management process, have led to a significant increase in

such assets as digital assets of business units (European Commission & High Representative, 2025). Such assets do not have a physical form and exist exclusively in digital form. Among the most widespread of these are smart contracts and cryptocurrency, which are based on the use of blockchain, as this ensures transparency, security, and efficiency of financial transactions. At present, their use is actively being implemented worldwide in various industries, such as finance, logistics, and trade. A more precise and comprehensive definition was provided by the European Financial A crypto-asset is defined as “a digital representation of value or contractual rights created, transferred and stored on some type of distributed ledger technology (DLT) network (e.g., Blockchain) and authenticated through cryptography” (European Financial Reporting Advisory Group (EFRAG), 2020).

The assessment and identification of digital assets have been the subject of studies by specialists from leading global consulting firms, commonly referred to as the "Big Four": PwC (2023), Deloitte (2021), Ernst & Young (2024), and KPMG (2023). According to their recommendations, the inclusion of cryptocurrency and other digital assets in the composition of intangible assets is the most conceptually justified approach.

Despite the substantial body of research on the assessment and identification of digital assets, in particular Peters et al. (2020), Miroshnichenko & Birch (2024), Yang et al. (2024), as well as in recommendations provided in IFRS-IAS 38, there remains a lack of consensus among researchers and practitioners regarding the classification of digital assets as intangible assets.

First and foremost, it should be noted that, in the author's opinion, digital assets can be qualified as "disclosed" assets (i.e., they can be reflected on a company’s balance sheet), since they have all the criteria of assets according to IFRS: identifiability, measurability, and directed to generate economic benefits by the owner. Secondly, the majority of digital assets meet the criteria of intangibility as defined in IFRS (IAS) 38(IFRS Foundation, 2024). However, the European Financial Reporting Advisory Group EFRAG (2020) recommendations indicate that digital assets that are the objects of purchase and sale transactions can be classified as inventories under IAS 2, (IFRS Foundation, 2024). Likewise, digital assets are not identified as a separate group in Brand Finance reports (Brand Finance, 2024). Meanwhile, considering the specific features of the recognition value of digital assets and their disclosure in financial statements is crucial for accurately understanding the potential value of an enterprise's intellectual capital and ensuring effective management of such assets.

Thus, the purpose of this study is to conceptualize and improve existing approaches to identifying and valuing intangible resources, with a particular emphasis on digital assets, as well as to develop accounting and analytical support to ensure the effective use of information and intellectual resources in the enterprise's business processes.

2. Methods

To substantiate the significance, needs, and requirements for developing an accounting and analytical framework to support the processes of forming and effectively managing intangible resources, the following research hypothesis was proposed.

Hypothesis: There is a statistically significant relationship between the set of indicators reflecting the dynamics of innovation activity in the industry $\{x_i\}$, (in particular, the growth rate of innovation expenditures, the volume of capital investments in intangible assets, the number of innovatively active enterprises), and a set of indicators characterizing changes in the efficiency of doing business in the industry $\{y_i\}$,(namely, the growth rate of total income, the share of profitable enterprises, and the profitability of operating activitiesof the sector).

To construct the canonical correlation models, data from official statistics of Ukraine for 2018-2020 (State Statistics Service of Ukraine, 2025) were used. Data for 2022 are not representative, as they reflect the impact of the war on business development.

The uniqueness of the canonical correlation method lies in the fact that it allows you to find the strongest possible correlation between two systems of indicators. No other method can determine the correlation between two systems of indicators in such a comprehensive way.

The problem of identifying the maximum possible correlations between the two sets of indicators is solved by introducing new variables - canonical functions, which are defined as linear combinations of the initial features. At the preliminary stage, the entire set of indicators was divided into two groups: explanatory features and outcome variables, which accumulate the effects of the former. For this purpose, the authors calculated the rates of change of the following indicators: costs for innovation activity in the

industry(x_1), the volume of capital investments in intangible assets (x_2), as well as the number of innovatively active enterprises in the industry (x_3)) in 2020 compared to 2018. In addition, the growth rates of the indicators of the effective plane were determined: total income (y_1), the share of profitable enterprises (y_2), and the profitability of operating activities of enterprises in the industry(y_3), (Appendix A, Table A1).

The study also applied the regression analysis method to determine the most significant factors from the set of explanatory variables ($x_{1,}, x_2$, x_3) that influence the integral indicator of the rate of change in industry income (y_1).

To develop the author's approaches to the identification and assessment of intangible assets in the enterprise management system and represent them in financial reporting, a comparative analysis of existing approaches presented in scientific sources and practical recommendations was conducted.

3. Results

To substantiate the significance and confirm the impact of capital investments on the formation of intangible assets characterizing the innovation activity of business units and their effect on business performance, canonical correlation models were constructed in the study. In particular, to derive two canonical functions, i.e., two new variables, uniquely defined by a given set of attribute values, two sets of variables were used - result indicators {y_i} and explanatory indicators {x_i}, which affect the results. The system of effective indicators is formed by the variables growth rate of income (y_1), growth rate of the share of profitable enterprises (y_2), and operating profitability growth rate (y_3). The attribute system contains such indicators as growth rate of capital investment in intangible assets (x_1), growth rate of innovation expenditure (x_2), and share of innovative enterprises' growth rate (x_3). Canonical variables can always be interpreted as complex indicators of the quality of two groups of features; therefore, they require the most careful study. The Statgraphics Centurion19 software environment was used for statistical data processing.

Therefore, the model of the relationship between two systems of indicators that describe the dependence of the change in the efficiency of doing business in the industry {Vi} on the innovation activity in the industry {Ui}, aimed at the formation of an intangible (informational and intellectual) resource, is represented of three ranked systems, Table 1.

Table 1. Results of Canonical Correlations

NN models	Description of Canonical Function Systems	Eigenvalue	Canonical Correlation	Wilks Lambda	Chi-Square	D.F.	P-Value
1	$U_1 = 0{,}688x_1 + + 0{,}524x_2 - 0{,}022x_3$ $V_1 = 0{,}962y_1 + 0{,}186y_2 + 0{,}531y_3.$	0,498974	0,706381	0,335102	71,6126	9	0,0000
2	$U_2 = -0{,}815x_1 + 0{,}915x_2 + 0{,}099x_3$ $V_2 = 0{,}506y_1 + 0{,}891y_2 - 0{,}308y_3$	0,245008	0,494983	0,66883	26,3457	4	0,0000
3	$U_3 = 0{,}085x_1 - 0{,}251x_2 + 1{,}01x_3,$ $V_3 = -0{,}152y_1 + 0{,}716y_2 + 0{,}883y_3$	0,114123	0,337821	0,885877	7,93709	1	0,0048

Source: own processing (2025)

The obtained results allow us to conclude that the first model of the system of two canonical functions most successfully describes the relationship between the set of explanatory and outcome variables. These two canonical variables (Ui and V_i) demonstrate a close relationship, as evidenced by the canonical correlation coefficient$r_{U_1V_1} = 0{,}706$. This relationship is formed by the indicators x_1, y_1, x_2, y_3.

A visualization of the relationship between canonical variables is provided in Fig. 2.

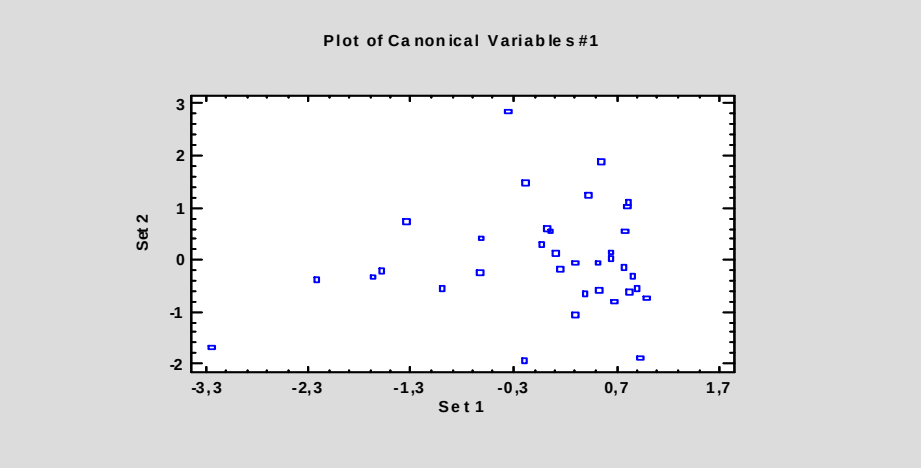

Figure 2. Results of the evaluation of the relationship between the resulting and characteristic canonical variables

Source: own processing(2025), based on the use of the software product Statgraphics Centurion 19

According to the second and third systems, the identified canonical variables exhibit a weaker relationship, as evidenced by the canonical correlation cofficients $r_{U_2V_2} = 0{,}495$ та $r_{U_3V_3} = 0{,}338$, respectively. It should be noted that although the correlation coefficients are lower, they are still significant according to Pearson's criterion. The relationship is formed in the second system by the indicators x_2, y_2, x_1, y_1, and in the third -x_3, y_3, y_2.

Thus, the conducted study confirms the presence of a statistically significant influence of indicators reflecting the dynamics of innovative activity in the industry$\{x_i,\}$, due to the use and further formation of intangible assets in the general area set of indicators by which the effectiveness of business processes of structural units (in our case, the sectors of the economy) is determined.

To determine the influence of three factors: growth rate of capital investment in intangible assets (x_1), growth rate of innovation expenditure (x_2), and the share of innovative enterprises' growth rate (x_3), on the performance indicator growth rate of income (y_1) , a multifactor regression model was calculated, which has the formula1:

$$y_1 = 2{,}031E6 + 372{,}51x_1 + 104{,}741x_2 \quad (1)$$

The results of the multiple regression analysis are presented in Table 2.

Table 2. Multiple Regression - Analysis of Variance

		Standard	*T*		
Parameter	*Estimate*	*Error*	*Statistic*	*P-Value*	
CONSTANT	2,03076E6	2,24356E7	0,0905148	0,9281

Residual		67	1,779E16		
Total (Corr.)		69			

Source: own processing(2025), based on the use of the software product Statgraphics Centurion 19

The third factor in the model was found to be insignificant according to the Student's criterion; therefore, it is excluded from the model. The coefficient of determination is sufficient $R^2 = 38{,}44$. Thus, the variability of the factors retained in the model explains 38.44% of the variability of the dependent indicator. This confirms the hypothesis of a rather high impact of these indicators on the overall growth rate of business efficiency in the economic sector.

Blockchain occupies a prominent position among digital assets, as its implementation has significantly influenced the financial processes of business entities and the organization of enterprise activities in general. According to Precedence Research (2024), the global blockchain technology market

was valued at USD 26.91 billion in 2024 and is projected to reach approximately USD 1,879.30 billion by 2034.

Modern business structures are actively exploring the possibilities of using blockchain technologies to create and effectively manage digital assets, such as smart contracts and digital currencies.

Blockchain technology in smart contracts is used to monitor logistics processes, verify data, preserve evidentiary information, and implement contractual automation. This contributes to market expansion and addresses the growing demand for secure transaction operations without the participation of intermediaries. According to the analytical report on the smart contracts market (Market.us, 2024), the global smart contracts market was valued at USD 1.9 billion in 2024. It is expected that by 2033, the demand for smart contracts will reach USD 14.9 billion. The forecast trend line of the smart contracts market, Fig. 3 (left-hand), demonstrates the accelerated growth of the market volume by 2033.

Similar trends are inherent in the global cryptocurrency market (Grand View Research, 2025), but the projected growth trend demonstrates a more restrained pace due to regulatory restrictions on the use of cryptocurrency, which are currently imposed in the majority of countries of the world (Fig. 3, right-hand).

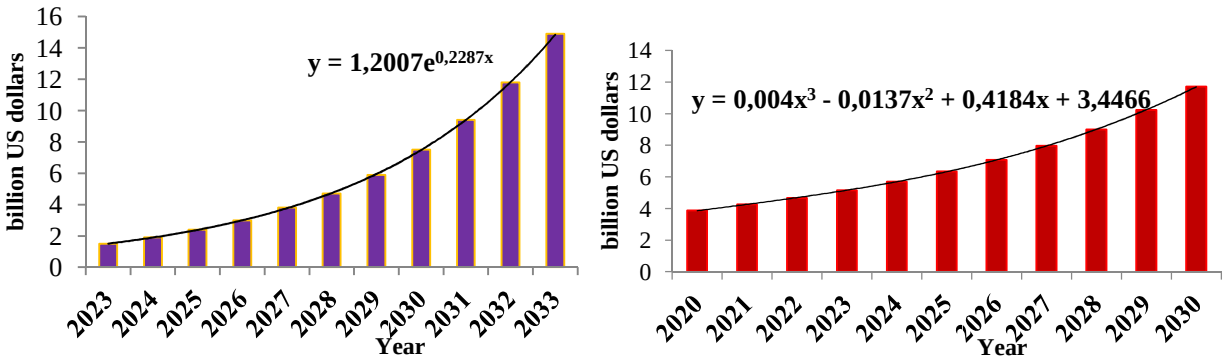

Figure 3. Actual volume (2023-2024) and forecast of the global smart contracts and cryptocurrency market

Source: own processing (2025) *based on Market.us, 2024, and Grand View Research, 2025*

Thus, the development of digital technologies, their integration into business processes not only transform traditional approaches to conducting business activities but also create new challenges and opportunities for enhancing business efficiency. In this context, the problem of developing approaches to identifying and reliably assessing digital assets, such as smart contracts and cryptocurrencies, in enterprise management and accounting systems is of particular significance.

According to the authors, a smart contract, as an intangible asset, should be recognized in the enterprise's accounting system and considered an object of managerial influence within the enterprise's management system. In this case, its cost should be determined by capitalizing the full development costs (TC), supplemented by the costs associated with setting up the management system for information and functional development support (RdC) and the performance of obligations by the parties to the smart contract (RoC)This approach differs significantly from IAS 38 (IFRS Foundation, 2024), which states that the value of an intangible asset is estimated based solely on the development or acquisition costs incurred. This concept does not recognize as capitalized the costs associated with hedging risks arising in the process of creating and using the asset. The structure of the proposed valuation model is presented in formula 2.

$$FC = TC + RdC + RoC \tag{2}$$

Where FC- the full capitalized cost of the smart contract

The composition of costs to be included in the assessment of an intangible resource in the form of a smart contract, to clarify its value as a management object within the enterprise management system, is presented in Table 3.

Table 3. Additional cost structure for joining the smart contract evaluation in the business unit management system

NN	Cost Category	Functional Purpose
Costs related to informational and functional support of smart contract ***development*** ***(R_DC)***		
1	Collection and preparation of information for preliminary description	Establishing a base for technical, legal, and analytical modeling of the contract
2	Adaptation of existing software	Integration of the smart contract with ERP systems (accounting, document management)
3	Legal support for development	Ensuring the contract's compliance with applicable legislation
4	Personnel training	Enhancing employees' qualifications for smart contract management
5	Formulation of technical requirements for developers	Defining smart contract requirements according to the legal framework and business goals
Costs related to informational and functional support of smart contract ***execution*** ***(RoC)***		
6	Accounting and analytical support	Ensuring the organizational, accounting, and analytical operations of the contract
7	Legal support during contract execution	Supporting contract execution and dispute resolution

Source: own processing (2025)

It should be noted that the costs listed in positions 2-4 of the table above are not capitalized in financial statements according to IA S38 (IFRS Foundation,2024). However, in the author's opinion, these costs constitute the additional value of intangible resources created in the process of activity, which reflects the formation of internally generated goodwill as a result of the implementation of innovations.

In the process of implementing and operating a smart contract within the management system, it is necessary to take into account the costs of risk management that are not subject to capitalization and are recognized as expenses of the period in which they are incurred. A clear classification of capitalized and non-capitalized costs provides a relevant information basis for making management decisions and assessing the effectiveness of using this intangible asset.

Blockchain is a digital asset that belongs to intangible assets, whose value is subject to reassessment during the period of its operation. At the same time, this asset is characterized by a relatively short period of use, typically no more than three years, and most often about one year from the moment of its implementation in business processes. Accordingly, the authors consider it is advisable to use an approach in which 50% of the cost of the blockchain is attributed to operating expenses immediately after creation (or acquisition), and the balance is amortized throughout use using the straight-line depreciation method.

Another digital asset used by modern enterprises using blockchain technologies is cryptocurrencies. As of March 2025, according to CoinMarketCap (2025), there are more than 10,000 types of cryptocurrencies circulating on the market. They are designed to replace Bitcoin or at least improve some of its parameters (for example, mining algorithm, coin distribution method, transaction speed). The most common of them are Ethereum, Tether, XRP, Figure 4, left-hand.

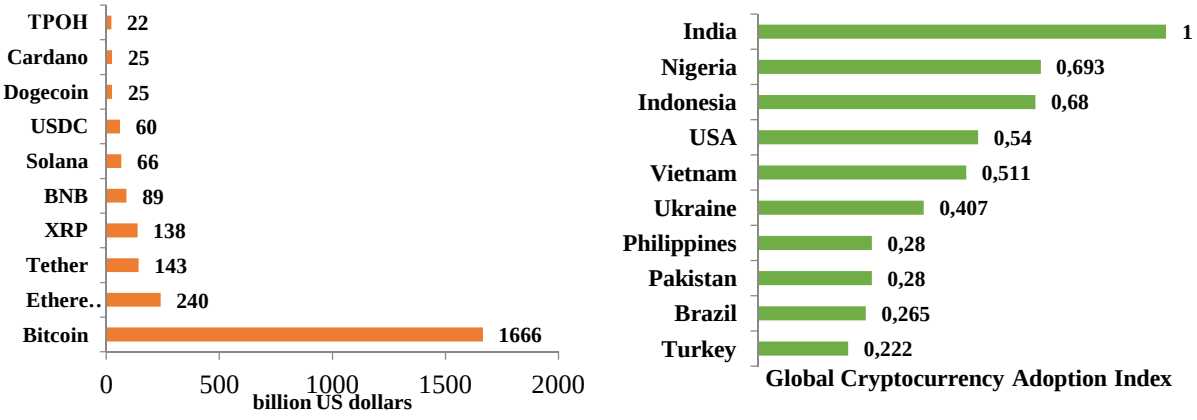

Figure 4. Overview of the Current Global Cryptocurrency Market
Source: own processing (2025) *based on CoinMarketCap (2025)*

The legal status of cryptocurrencies varies significantly in different countries and continues to evolve in many of them. In most countries, cryptocurrencies are not recognized as legal tender, but can be used as a commodity or a store of value. Such countries include, in particular, the United States, Canada, Great Britain, Japan, Australia, Spain, Germany, Ukraine, Mexico, and Argentina, among others. The use of cryptocurrency, specifically Bitcoin, as a means of payment is legally permitted by the two countries: El Salvador and the Central African Republic. Despite the global spread of cryptocurrency, there are still countries where its use is entirely prohibited by law, including Bolivia, Algeria, and Pakistan (Cryptomus, 2024).

In the current context of increased volatility of major global currencies, cryptocurrency is increasingly being used by business entities in different countries as a tool for minimizing financial risks. At the same time, the current regulatory framework still lacks both national and international standards that regulate the accounting procedure for cryptocurrencies. This situation necessitates the assessment of the compliance of such digital assets with the recognition criteria established in IAS 38 Intangible Assets or IAS 2 Inventories (IFRS Foundation, 2024).

Given the significant volatility in cryptocurrency market prices, their valuation in monetary terms is accompanied by a number of methodological challenges. If their initial measurement, according to many scholars (Jackson, A. B., & Luu, S. (2023), Peters et al. (2015), Crumbley et al. (2024), should be carried out using the methodology of full costs of its acquisition (or mining), their subsequent revaluation presents many difficulties.

A common method of hedging the risks associated with storing assets in cryptocurrency is the use of stablecoins. Stablecoins are programmable digital currencies that are typically pegged at a 1:1 ratio to fiat currencies. Issued primarily on blockchain networks such as Ethereum and Tron, stablecoins combine the power of blockchain technology with the financial stability required for practical use of cryptocurrencies, making their use increasingly widespread. The most widely used stablecoins currently include USDT and USDC (Cointelegraph,2025).

Having analyzed existing approaches, the authors tend to support the first of the outlined methodologies, but propose the use of revaluation of the value of the cryptocurrency on the date of reporting or at the date of its disposal based on the binding of its value to fiat currencies such as the US dollar or the Euro.

4. Discussion

The results of the conducted canonical analysis of the influence exerted by the system of indicators characterizing the innovative activity of a business unit in the process of creating and utilizing intangible assets on the system of business efficiency indicators demonstrate the need to expand and refine the set of descriptive indicators. In particular, the list of such indicators should include not only the volume of investments in intangible assets recognized in financial statements, but also the total volume of investments in intangible resources, which may not always meet the criteria for recognition as assets. However, the lack of statistical data on evaluating business processes at the industry level makes it impossible to implement such an approach in practice. This, in turn, justifies the need to calculate internally generated goodwill as an integral indicator that reflects the presence of a formed but unidentified information resource of the enterprise.

Studies examining the impact of intangible assets on income and return on capital indicators are presented in the works of Méndez Morales et al. (2024), Jancenelle (2021), and Bagna et al. (2024), all of which, through the use of alternative mathematical tools, confirmed the existence of a positive impact. The uniqueness of the methodology proposed by the authors lies in the assessment of the overall influence exerted by a system of descriptive indicators that characterize the formation and use of intangible resources in the process of innovation activity, on the system of resulting indicators (in particular, changes in the growth rates of industry income, overall profitability and the share of profitable enterprises). This made it possible to identify the most significant characteristic indicators from the point of view of impact, as well as to select the resulting indicators that are most affected by them.

It is also worth acknowledging the viewpoint of Milenović, Teofilović, and Lukić (2024), Semenova et al. (2025) regarding the significance of effectively utilizing total intellectual capital, which encompasses both the identified part of disclosed assets in financial statements and the unidentified part of intangible resources, in achieving the target profitability of companies.

In the study Dragomir (2024), particular attention is drawn to the existing significant impact of asset structure (the share of intangible assets in the total volume) on the enterprise`s ROI. Dragomir (2024) highlights a reverse relationship between profitability and investment in intangible assets, which is deemed illogical and is directly attributed to deficiencies in cost accounting and the financial reporting practice of recognizing only intangible assets, while omitting the broader scope of intangible resources. This once again underscores the need to improve the assessment of digital assets, both disclosed (capitalized) and their non-disclosed part, Azimov et al.(2024). In particular, the author's approach to the valuation of such a digital asset as smart contracts is based on this approach.

From the perspective of evaluating cryptocurrencies as part of an intangible resource, considered as of management influence, their value during the period of use may be assessed according to various models. The first approach involves the valuation at historical cost less any accumulated impairment losses. However, according to many scholars, including Alsalmi et al. (2023), Huang et al. (2023), and Parrondo (2023), the relevance and practical utility of this model for assessing cryptocurrencies are questionable, particularly when the primary purpose of holding cryptocurrency is capital appreciation due to price fluctuations. In such cases, accounting data fails to reflect the true market value of these assets. An alternative accounting policy, consistent with IAS 38 and IAS 13 (IFRS Foundation, 2024), is the revaluation model, which is considered more acceptable by many scholars (Elsayed, R. A. (2025); Lazea et al., 2023). According to this model, a cryptocurrency should be measured at its fair value at the revaluation date, less any subsequent accumulated impairment losses.

The authors adhere to the latter approach, but propose to determine the value of the acquired cryptocurrency by converting it into the value of major world currencies, with subsequent revaluation using the approaches applied to “monetary” assets. At the same time, since cryptocurrency is not recognized as legal tender, it does not meet the criteria for monetarism, and therefore, such a classification is conceptually contradictory. These include income, overall profitability, and the share of profitable enterprises within a sector.

Conclusion

The study analyzed the global dynamics of corporate asset growth, divided into tangible and intangible components. It was found that intangible assets demonstrate outpacing growth both in value terms and in their share within the overall structure of companies' assets compared to tangible ones.

Based on the application of canonical analysis methods, the hypothesis of a significant impact of the system of indicators characterizing the formation of intangible assets in the context of innovative activity of business entities (across specific sectors of the economy) on the system of resulting indicators of business processes has been confirmed. This is confirmed by the canonical correlation coefficient $r_{U_1V_1} = 0{,}706$, which was formed by the influence of the indicators of the growth rate of capital investment in intangible assets, growth rate of innovation expenditure on growth rate of income, and operating profitability growth rate.

The results of multiple regression analysis demonstrate a significant influence, at the level of 38%, of the indicators of investment in intangible resources and innovative activity of enterprises in the industry on total industry income. These findings underscore the need for further improvement of approaches to the identification and assessment of intangible assets, such as digital assets/

The conducted analysis, based on publicly available statistical sources, has presented stable trends in the increasing use of digital assets, particularly blockchain, smart contracts, and cryptocurrencies, in the economic activities of business entities worldwide.The research findings propose approaches to improving the methods for evaluating smart contracts as objects of managerial influence used for decision-making within a management system. Particular emphasis is placed on incorporating previously unaccounted information regarding the informational and intellectual resources generated during the development and implementation of smart contracts within an enterprise, to ensure a more accurate assessment of their value.

The global cryptocurrency market is rapidly evolving, transforming traditional ideas about financial instruments. Ukraine ranks among the leading countries in terms of cryptocurrency adoption, which indicates a high potential for the development of financial innovations. To enable a reliable assessment of cryptocurrencies as a means of minimizing enterprise financial risks, recommendations have been developed regarding the accounting treatment of their value at the stages of acquisition (mining), revaluation, and disposal.

Level of Digitalization of Communication Media with the Public in Selected Cities

***Marcel* Lincényi**[1,*]**, *František* Vojtech**[1]**, and *Miriam* Slobodníková**[2]

[1] Bratislava University of Economics and Management, Institute for Economics and Management, Department of Small and Medium Enterprises, Furdekova 16, 851 04, Bratislava, Slovakia
[2] LEGAL TENDERS, sro Dobrovičova 120/4, 811 02 Bratislava, Slovakia

Abstract

Research background: The main objective of the contribution is to define the concept of digitalization of society, to point out the needs and reasons for its emergence, as a response to the acute solution of the problems of citizens living in these cities and towns. Intelligent, i.e. smart technologies create possibilities for solving the changes that municipalities and cities face as a result of urbanization and population growth. However, this solution is only possible in cooperation with legislation that will respond quickly and professionally to the ongoing changes.
Purpose of the article: The next part of the article is devoted to the growing communication problems that smart municipalities and cities can solve by implementing innovative solutions in individual areas of the city economy and is the output. The article therefore focuses on the analysis of the basis for the use of innovative solutions in the field of digitalization of communication media by local government entities using the example of the Slovak Republic. Based on the current legal regulation, it defines the essence of local government, analyzes the possibilities, means and procedure of municipalities and cities in implementing smart solutions.
Methods: The research part of the paper will draw on the results of an international research project in which four cities in the Prešov and Košice regions were evaluated. 12 criteria were evaluated in each city. This paper will be based on the evaluation of one of these criteria, namely: "Level of digitalization of communication media with the public" in each evaluated city.
Findings & Value added: Based on the analysis of the results obtained, the authors proposed procedures for individual cities on how the level in this area could be improved.

Keywords: Innovation, Modernization, Local Government, Environment, Smart City

1. Introduction

In the introduction, we will present the conditions of the concept of digitalization of society, point out the needs and reasons for their emergence, as a response to the acute problems of citizens living in these cities and municipalities. In smart cities, sustainable urban development is achieved through "new, efficient and user-friendly technologies and services, in particular in the areas of energy, transport and ICT" (European Court of Auditors, ECA Special Report, 2023). In addition to using technologies to save resources and reduce pollution, a smart city also aims to make city services more responsive and accessible, to make public spaces safer and to improve transport, water and waste management, street lighting and building heating. (Ministry of Education, Research, Development and Youth of the Slovak Republic, 2014) “The ability to adapt to and use digital technologies will be a key factor for success in an increasingly digital business environment.” (Ivanová, Kordoš et al., 2024)

In the article, we present a view of the Smart City and its impact on the quality of life of citizens, as well as legislative regulation in terms of the possibilities of intelligent local government in the Slovak

[*] Corresponding author: marcel.lincenyi@vsemba.sk

Republic, or smart cities, which is related to the use of information and communication technologies. (Machyniak, Mikuš, Dzureková, 2023)

One of the evaluation criteria: " The level of digitalization of communication media with the public " in the project "Socio-economic strategy for the development of climate-neutral and smart cities and its importance for the private and public sector", in two regions: the Prešov region and the Košice region, based on the available information, it gives us a picture of the current state of development of digitalization of selected 8 cities from the above-mentioned 2 regions of Slovakia.

2. Methods

Research file selection

For a more detailed analysis, 4 cities from the Prešov region (Levoča, Prešov, Sabinov, Vysoké Tatry) and 4 cities from the Košice region (Spišská Nová Ves, Trebišov, Michalovce, Sobrance) were selected.

Evaluation criteria

The research focuses on multiple criteria of smart cities, with this paper specializing in the level of digitalization of communication media with the public.

Other criteria include: Smart city strategy/vision, feasibility study, information about the smart city vision in other documents, city services for residents available in the form of applications, digitalization of administrative service support for the population, level of use of digitalization in environmental protection, smart technology in energy, population safety, public lighting, smart technology in transport and digitalization of city fees and taxes.

Data collection and analysis

The data was obtained from public city websites and published documents.

The evaluation was carried out on a point scale, with weights assigned by 3 independent evaluators, including a city representative.

This approach increases the validity and reliability of the research.

2.1 The concept of smart cities in the Slovak Republic

The term Smart City is not completely unknown. To clarify it, we can characterize this term as the management of a city in its various areas through information and communication means. Its implementation is oriented towards the various urban areas for which the city is responsible.

Cities on the path to Smart must define a strategy, define goals and start implementing specific projects. Subsequently, the deployment of technologies creates space for local governments to obtain large amounts of data that can be used for management. For what management? The obtained data can be further analyzed and evaluated. Based on them, it is possible to adjust parking policies, adjust the number of garbage cans in cities, create low-emission zones, etc. The team of authors (Štofejová, Kráľ, Fedorko, Bačík et al., 2023) point out that environmental awareness among consumers is increasing, as they begin to prefer sustainable products and services. "It can be assumed that the competitiveness of companies in the future will depend greatly on how companies are able to implement the principles of the circular economy." (Levický, Fiľa et al., 2022)

However, city managers must understand the importance of data for the development of individual cities. If they have data but cannot use it to their advantage, they will never move the city closer to sustainability. That is why management is an important part of every city. However, it is primarily associated with the management skills of representatives.

In the Slovak Republic (hereinafter referred to as “SR”), the topic of smart cities and regions has been gaining increasing attention in recent years, both from the cities themselves and higher territorial units (hereinafter referred to as “HTU”), as well as from independent experts, innovative companies and the state. Cities and regions are gradually experimenting with sharing open data, introducing modern technologies, building professional and analytical capacities directly at the offices and involving the professional and general public in decision-making. At the same time, an important mushroom of independent experts, interest groups and innovative startups focused on developing new and improving existing tools in public administration is emerging in the country.

In Slovakia, the topic of smart cities and regions has been gaining increasing attention in recent years, both from the cities and higher education institutions themselves, as well as from independent experts, innovative companies and the state. Cities and regions are gradually experimenting with sharing

open data, introducing modern technologies, building professional and analytical capacities directly at the offices and involving the professional and general public in decision-making. At the same time, an important mushroom of independent experts, interest groups and innovative startups focused on developing new and improving existing tools in public administration is emerging in the country.

In previous years, the state has made several efforts to support the topic of smart cities and regions, mainly through financial contributions from the European Union (hereinafter referred to as the "EU"), for example in the form of projects to support the professional capacities of local government, the development of digital and data services of public administration, the support of innovative solutions for small and medium-sized enterprises (hereinafter referred to as the "SMEs") in local governments, or projects focused on green renewal and adaptation to the climate crisis and mitigating its consequences. At the system level, the legislative and methodological framework is formed by Act No. 539/2008 Coll. on the support of regional development, as amended (Act No. 539/2008 Coll. on the support of regional development) (hereinafter referred to as the "Regional Development Act") and the Methodology for the creation and implementation of economic development and social development programs for the programming period after 2020, which is available in the updated version from February 2022. This methodological document contains a special Annex No. 6 entitled Smart sustainable development as a target quality of development strategies, which emphasizes the connection between the conceptual and implementation dimensions of the smart development strategy.

An important step was the transformation of the Office of the Deputy Prime Minister of the Slovak Republic for Investments and Informatization (hereinafter referred to as “ÚPVII”) into the Ministry of Investments, Regional Development and Informatization of the Slovak Republic (hereinafter referred to as “MIRRI SR”) covering the agenda of regional development, coordination of the use of financial resources from EU funds and digitalization of public administration. The connection of these three extensive agendas is key for an effective policy of supporting smart cities and regions as self-governments using information and communication technologies (hereinafter referred to as “ICT”) and access to EU resources for the creation of integrated solutions contributing to sustainable regional development. In this context, MIRRI SR therefore has a unique opportunity to become the national coordinator of the smart cities and regions agenda in the Slovak Republic, ensuring the consistency and compatibility of policy at the national level with the development needs, interests and requirements of self-governments, while the first steps towards this position are already in the process of implementation. Thanks to a national project supported by the Operational Programme Effective Public Administration (hereinafter referred to as "OP EVS"), a special methodological and evaluation unit was established to support the development of smart cities and regions. The agenda of smart cities and regions is brought together in one place within MIRRI SR, i.e. in the section of innovations, strategic investments and analyses (HUB). The Programme Slovakia 2021 - 2027 (hereinafter referred to as "P SK") also includes the smart development of cities and regions across all policy objectives and allocates an amount exclusively to support this issue (Ministry of Investments, Regional Development and Informatization of the Slovak Republic, Action Plan of Smart Cities and Regions for 2023 - 2026, 2022).

Another document that is of fundamental importance for the practical implementation of Smart City is "Support for Innovative Solutions in Slovak Cities", which was prepared and published by the Ministry of Economy of the Slovak Republic (hereinafter referred to as the "ME SR").

The concept of Smart City has become a trend that the Slovak Republic is currently facing. In Slovakia, the city of Kežmarok recently presented its own Smart City concept, the city of Poprad initiated the creation of the Slovak Smart City Cluster, and the city of Nitra presented a proposal for the implementation of the Smart City concept. According to information from the Ministry of Economy of the Slovak Republic, 10 Slovak cities are preparing to develop similar plans in the coming months (Ministry of Economy of the Slovak Republic, Support for Innovative Solutions in Slovak Cities, 2017).

2.2 The use of mass media in the development of the Smart City concept

Smart City concept represents a modern approach to urban management and development that uses digital technologies, data analytics and intelligent solutions to improve the quality of life of residents, increase the efficiency of urban services and promote sustainability. In this process, mass media play an important role as a mediator of information, a facilitator of public debate and a tool for supporting civic participation. Mass media have several possibilities of use in the development of the Smart City concept:

Informing and educating the public - Mass media (television, radio, press, internet portals, social networks) are the basic channel for disseminating information about prepared and implemented smart projects. Through news, programs, documents or reports, city residents can gain an overview of new technological solutions that can make their everyday lives easier - e.g. smart lighting, digital parking, air quality monitoring or smart waste management. At the same time, the media fulfill an educational function - they increase digital literacy and prepare residents to adapt to new technologies. This is especially crucial for older generations or socially vulnerable groups who may feel threatened by technological changes.

Support for citizen participation - Smart City is not only about technology, but especially about people. A successful smart city actively involves its citizens in decision-making processes. The media can significantly contribute to informing citizens about the possibilities for participation - whether it is public discussions, voting, sharing ideas through participatory platforms, or evaluating the functionality of smart solutions. Interactive media formats, such as online broadcasts of discussions, podcasts, comments on social networks or specialized mobile applications, allow citizens to express their opinions and directly influence the direction of the city.

Transparency and trust - Cities that communicate their actions transparently through mass media build the trust of citizens. Regular publication of data on the budget, public procurement, project results or feedback from citizens supports open self-government. Transparency is a key principle of smart cities - the public has access to open data, follows the development of projects in real time and knows how public funds have been used. The media thus also acts as a control mechanism and guardian of the public interest.

Crisis and operational communication - In the event of a crisis (natural disasters, pandemics, service outages), mass media are essential for rapid and effective communication between the municipality and the public. The city can quickly warn residents, coordinate evacuations, provide updates or guidance through television, radio, social networks or push notifications in city applications. Smart cities integrate media into their crisis plans as an active tool for early warning and management of emergency responses.

Promoting smart solutions and building a city's image - Mass media also serves as a marketing tool for promoting an innovative and technologically advanced image of the city. By presenting smart projects, cities can attract investors, startups, experts and tourists. At the same time, they inspire other cities to similar initiatives. The media can highlight successful examples - e.g. reducing CO_2 emissions through electromobility, better traffic management using smart traffic lights, or increasing safety through an intelligent camera system. Mass media are an integral part of the development of the Smart City concept. Their proper use can significantly contribute to the awareness, engagement and satisfaction of residents. Thanks to them, a smart city can become not only technologically advanced, but also an inclusive, transparent and participatory space for living.

In the development of the Smart City concept, it is possible to use print, electronic and new media at the national, multi-regional, regional and local levels. Among the most popular mass media today are social media. A team of experts (Supeková, Keklak, Masarová, Jakešová, 2023) emphasize that social media and networks have become not only a digital phenomenon of recent decades but also represent a digital space of unexpected future possibilities. "They are becoming an inimitable tool and medium for marketing companies, especially means of their promotion and advertising. At the same time, however, they are also important in many other areas, not only as sources of information, but also as means of contemporary interpersonal communication." As stated by the authors Igarová, Kádeková, Košičiarová (2023, p. 166), today almost every company has a profile on social networks such as Instagram, Facebook and YouTube. Companies can use elements of influencer marketing, which is considered a modern phenomenon, within social networks.

3. Results

The most important criteria included: smart city strategy/vision, feasibility study, level of digitalization of communication media with the public, city services for residents available in the form of applications, level of use of digitalization in environmental protection, level of use of smart technology in energy, and level of use of digitalization of city fees and taxes.

We will take a closer look at the level of use of digitalization of media communication with the public in the Prešov Region and the Košice Region, which we will present more specifically in this article.

3.1 Evaluation in the Prešov Region

In the regional assessment of the level of use of digitalization of communication media with the public according to the table below, the best ranked city was Vysoké Tatry with 0.28 points, followed by Levoča with 0.25 points, the city of Prešov with 0.2 points and the city of Sabinov with a total of 0.18 points. Given the fact that the environment covers a wide range of possibilities for its protection, the individual approaches of the cities are also different.

In the City of Vysoké Tatry, in the area of the level of use of digitalization of communication media with the public, they have published the Tatra biweekly on the website.

Levoča has a Facebook profile, LIMKA - interviews and Levočský TV weekly on its website.

The city management of Prešov tries to communicate with the public through regular mass media outputs (social networks, city periodicals, etc.). Part of the higher level of communication with the public are also either ongoing or prepared participatory processes, when the city wants to hear about the problems of residents, or about their needs. Citizens can obtain information from the city website, social networks _FB, Instagram, Prešovský magazín (it is distributed to households and published on the city website), sms applications info. At the same time, the city provides online live broadcasts of the meetings of the Prešov City Council.

In Sabinov, they have set up a profile on the social network Facebook and an official board on their website for the purpose of communicating with residents.

Table 1. Rating in the Prešov Region

Evaluation area – criteria	**Weight**	**Total evaluation criteria evaluation commissions**			
	0.01 – 1.00	**SABINOV**	**VYSOKÉ TATRY**	**LEVOČA**	**PREŠOV**
	Representative the city which rated:	**Mr. Bass Player**	**Mr. Ganzarčík**	**Mr. Novotná Tea**	**Mr. Dubecká**
Level of use of digitalization of communication media with the public	0.03	0.18	0.28	0.25	0.2
Order		4.	1.	2.	3.

Source: Own development of smart city assessment.

3.2 Evaluation in the Košice region

In the regional assessment of the level of use of digitalization of communication media with the public according to the table below, the best ranked city was Spišská Nová Ves with 0.26 points, followed by the city of Sobrance with 0.21 points, the city of Trebišov with 0.17 points and the city of Michalovce with a total of 0.09 points.

In the area of the level of use of digitalization of communication media with the public, the City of Spišská Nová Ves has its own television - TV Reduta, a city website, a Facebook profile and a YouTube profile.

The city of Sobrance has a Facebook profile, a city website, a city newspaper - Sobrančan, and a city TV - Sobranská televízia.

The city of Trebišov communicates with the public through its website in the official bulletin board, city newsletter, and questions and answers sections.

The city of Michalovce has published - City in your pocket, eDoc, communication via the city website, social networks.

Within the two evaluated regions, the best position was achieved by the City of Vysoké Tatry, which we expect will be an inspiration for other cities in the application possibilities of the level of use of digitalization of communication media with the public.

Table 2. Evaluation in the Košice region

Evaluation area – criteria	**Weight**	**Total evaluation criteria evaluation commissions**			
	0.01 – 1.00	**Michalovce**	**Sobrance**	**Spišská Nová Ves**	**Trebišov**
	Representative the city which rated:	**Mrs. Machová ***	**Mrs. Iškyová**	**Mr. Pohly**	**Mr. Dembická**
Level of use of digitalization of communication media with the public	0.03	0.09	0.21	0.26	0.17
Order		4.	2.	1.	3.

Source: Own development of smart city assessment.

4. Discussion

The concept of digitalization within Smart City projects is significantly affected by the lack of qualified employees. This situation affects not only the planning and implementation of digital solutions, but also their long-term sustainability, management and development. Several authors point out the lack of Slovak employees: (Karácsony, Czókolyová, Mura et. al. 2024, Kömüves et al., 2024).

Digitalization in urban environments requires experts from various fields – IT specialists, data analysts, project managers, cybersecurity experts, infrastructure management. The lack of qualified workers leads to delays in the deployment of smart technologies such as sensors for traffic monitoring, smart lighting or real-time data collection systems.

Without adequate staffing, digital solutions are often implemented without thorough planning, testing, and monitoring. This can lead to lower quality of service, higher system failure rates, and reduced citizen satisfaction. Furthermore, if a team is not in place to continuously manage, update, and evaluate solutions, their long-term sustainability is reduced.

The lack of employees is not just a personnel problem but fundamentally affects the success and quality of the digitalization of cities. The solution can be systematic internal capacity building, close cooperation with universities, support for education in digital skills, flexible working models and sharing of know-how between cities. However, without sufficient personnel security, the vision of a truly smart city is difficult to implement.

Conclusion

The results of the evaluation of the project criteria are intended to serve to better orient cities in the field of smart cities, to ensure their development in this area, which will make life easier for residents and support communication between the city and its residents in the area of many monitored services.

The cities evaluated have published the following in terms of the level of use of digitalization

of communication media: online city periodical, city television, online interviews and broadcasts of city council meetings on the website, as well as an official bulletin board, city newsletter, questions and answers, social networks: Facebook, Instagram and YouTube profile.

The above methods of communication are easily applicable to other cities.

The first results of the research show that the level of digitalization of district towns is at different levels and some towns will need help in this regard. The results of this research represent an important step towards understanding and improving the use of digitalization in the area of the level of digitalization of communication media with the public in Slovak towns and are an inspiration in the area of improving the digitalization of all district towns.

After the evaluation phases of individual cities are completed, it will be possible to define proposals for improving individual levels of smart cities and propose basic criteria for the creation of smart cities, whether in Slovakia, Ukraine or internationally. Thus, increasing the standard of living of residents of municipalities and cities.

Acknowledgements

The contribution is part of the project: 3/2023-M Socio-economic strategy for the development of climate-neutral and smart cities and its importance for the private and public sectors.

Transformative Intelligence as a Core Competency for Educational System Management: Integrating Organizational, Technological, and Human Dimensions in 21st Century Leadership

Enrique **Messer**[1,*] **and** ***Reuven*** **Azulay**[2]

[1] Gaia College, Faculty of Management, Jerusalem, Israel
[2] David Yellin Academic College of Education, Faculty of Education, Jerusalem, Israel

Abstract

Research background: Contemporary educational systems face unprecedented challenges requiring fundamental transformations in leadership approaches within increasingly complex digital, social, and global environments.
Purpose of the article: This study presents Transformative Intelligence (TI) as a meta-systemic competency essential for educational leaders navigating the convergence of pedagogical innovation, organizational complexity, technological integration, and human development needs.
Methods: The research employs a systematic integrative literature review methodology across PsycINFO, ERIC, Web of Science, and Google Scholar databases (2000-2024), coupled with case study analysis of educational transformation. A three-level thematic analysis identified patterns across research domains while maintaining sensitivity to disciplinary differences.
Findings & Value added: Through systematic integration of psychological flexibility principles, artificial intelligence capabilities, and humanistic educational approaches, this research develops a comprehensive theoretical framework demonstrating how educational leaders can effectively implement technological innovations while preserving human-centered approaches. Empirical validation through case study analysis reveals transformative intelligence as a foundational meta-competency enabling leaders to maintain effectiveness during technological implementation, crisis management, and stakeholder relationship preservation. The research advances educational leadership theory by bridging psychological adaptability, technological innovation, organizational learning, and contemplative pedagogy while providing practical guidance for institutions seeking sustainable excellence in complex 21st-century environments.

Keywords: Transformative intelligence, Educational leadership, Psychological flexibility, AI integration, Contemplative pedagogy, Organizational transformation

JEL classification: J53, M12

1. Introduction

Educational institutions worldwide operate within unprecedented complexity (Fuchs, 2024), characterized by technological disruption, global crises, demographic transformation, and evolving societal expectations that demand enhanced leadership capabilities transcending traditional management paradigms (Avolio et al., 2009). The convergence of artificial intelligence capabilities, psychological adaptability requirements, and crisis management necessities has created complex dynamics across educational sectors, requiring leadership frameworks that integrate human-centered approaches with technological innovation while maintaining educational effectiveness during uncertainty and rapid change.

Contemporary educational leaders must simultaneously manage technological integration without compromising educational values, coordinate diverse stakeholder communities with varying expectations, develop organizational resilience capable of adapting to multiple simultaneous crises, and ensure

* Corresponding author: messerari@gmail.com

equitable access while optimizing resource allocation through innovative approaches (Bass & Riggio, 2006). The complexity of modern educational leadership extends beyond traditional instructional or administrative domains to encompass crisis management, technological stewardship, multicultural community building, and psychological support for entire educational ecosystems experiencing unprecedented stress and uncertainty.

This transformation necessitates what emerging scholarship identifies as transformative intelligence, defined as the meta-systemic capacity to identify, understand, and modify dynamic interactions between perception of reality and functioning within it, enabling adaptive and generative responses to complex changing environments (Hayes et al., 2006). Unlike traditional intelligence paradigms that conceptualize capabilities as fixed traits, transformative intelligence operates as a dynamic process integrating perceptual flexibility, adaptive functional capability, ecological engagement, and transformative creativity within unified theoretical frameworks.

The urgency of developing comprehensive leadership frameworks becomes evident when examining contemporary educational challenges. Educational leaders face organizational and financial collapse, characterized by unprofessional governance, toxic organizational culture, severe budget deficits, and neglected physical and educational infrastructure. These challenges demonstrate the practical applicability of transformative intelligence frameworks while highlighting the essential integration of technological innovation with human-centered approaches.

However, significant gaps exist in both theoretical understanding and practical frameworks for preparing and supporting educational leaders in navigating this complexity. Existing leadership theories often treat psychological adaptability, technological competence, and organizational transformation as separate domains requiring distinct approaches and fail to address their synergistic interactions in real-world leadership contexts (Judge & Piccolo, 2004). Traditional educational leadership preparation programs, developed for more stable and predictable environments, often lack systematic attention to crisis management, psychological resilience, and technological integration as core competencies rather than supplementary skills.

2. Methods

2.1 Research Design

This study employs a systematic integrative literature review methodology designed to synthesize theoretical frameworks across multiple domains and identify convergent patterns supporting the development of Transformative Intelligence theory. The research follows a mixed-methods approach combining theoretical synthesis with empirical case study analysis.

2.2 Search Strategy and Data Sources

A comprehensive search strategy was implemented across four major databases: PsycINFO, ERIC, Web of Science, and Google Scholar. The search parameters included peer-reviewed articles published between 2000-2024 in English and Hebrew languages. Key search terms encompassed: "educational leadership," "psychological flexibility," "AI education," "contemplative pedagogy," "transformational leadership," and "organizational transformation."

2.3 Inclusion and Exclusion Criteria

Inclusion criteria: Peer-reviewed articles focusing on theoretical frameworks, empirical studies, and case analyses related to educational leadership, psychological flexibility, artificial intelligence in education, and contemplative pedagogy. Studies were required to demonstrate academic rigor, theoretical contribution, and empirical support.

Exclusion criteria: Non-peer-reviewed sources, publications before 2000, opinion pieces without empirical foundation, technical manuals, and preliminary studies with limited validation.

2.4 Data Analysis

The theoretical synthesis employed a three-level thematic analysis designed to identify patterns across research domains while maintaining sensitivity to disciplinary differences:

Level 1 (Foundational): Analysis of intelligence definitions, leadership theories, and technology roles
Level 2 (Integrative): Examination of cross-domain relationships and synergistic effects
Level 3 (Meta-theoretical): Investigation of paradigmatic shifts and future directions

2.5 Case Study Methodology

The research includes analysis of an educational transformation case study demonstrating practical application of transformative intelligence principles. The case study follows established qualitative research protocols for organizational transformation analysis.

2.6 Quality Assessment

All included sources underwent quality assessment based on academic rigor, theoretical contribution, and empirical support. Priority was given to high-impact journals and established researchers in the field.

3. Results

3.1 Evolution of Educational Leadership Theory

Educational leadership theory has undergone profound transformation over the past century, evolving from rudimentary hierarchical models to adaptive frameworks reflecting the multifaceted nature of modern educational institutions. This evolution represents a fundamental paradigm shift driven by changing societal expectations, technological advances, and deeper understanding of organizational dynamics and human behavior in educational settings (Burns, 1978).

The transformation reflects growing recognition that educational institutions operate as complex adaptive systems, where leadership effectiveness depends not solely on formal authority but on the capacity to facilitate learning, innovation, and positive change across multiple organizational levels and stakeholder communities during both stable and crisis periods (Spillane, 2006).

Contemporary educational leadership theory encompasses integrated models that synthesize elements of instructional, distributed, and transformational leadership approaches, reflecting how contemporary school leaders utilize different leadership types in varying situations while coordinating with teachers to influence instruction and learning outcomes (Leithwood & Jantzi, 2000).

3.2 Psychological Flexibility and Educational Leadership

Psychological flexibility theory, developed within Acceptance and Commitment Therapy frameworks, offers comprehensive understanding of maintaining effectiveness during challenging circumstances through six core processes that operate synergistically to create effective and values-based behavioral patterns (Hayes et al., 2006). Recent research demonstrates that psychological flexibility serves as a crucial meta-competency for contemporary organizational leaders, with particularly strong correlations between flexibility components and leadership effectiveness during change management and crisis contexts.

Cross-cultural empirical research involving diverse adult and adolescent populations consistently demonstrates that psychological flexibility predicts enhanced life satisfaction, reduced symptoms of depression and anxiety, and improved physical health outcomes across various contexts (Bond et al., 2013). Research among educational professionals reveals that psychological flexibility significantly moderates stress effects, demonstrating protective capabilities in adversity that parallel challenges faced by educational leaders in diverse school communities.

3.3 Artificial Intelligence Integration in Educational Management

Artificial intelligence applications in educational management represent fundamental shifts from simple automation toward complex systems that analyze patterns, make predictions, and adapt based on experience while maintaining human oversight and ethical standards (Holmes et al., 2019). Contemporary AI applications encompass predictive analytics that identify at-risk students through multiple data streams, intelligent communication systems providing continuous stakeholder support, smart resource management optimizing facility utilization and scheduling, and data-driven decision support aggregating information for strategic planning.

The integration of AI-enhanced assessment with psychological flexibility development represents a paradigm shift toward data-driven yet human-centered approaches to leadership development, enabling precise identification of development needs while maintaining focus on authentic relationship-building and values-based decision-making essential for educational leadership effectiveness.

3.4 Transformative Intelligence Theoretical Framework

Transformative Intelligence represents a meta-systemic capacity integrating four core components functioning through recursive feedback loops (Fuchs & Fuchs, 2025). Perceptual flexibility encompasses

meta-cognitive awareness, enabling perspective shifts across meaning-making systems, challenging individuals to recognize the constructed nature of experiential reality while maintaining sufficient psychological coherence to function effectively across diverse contexts.

Adaptive functional capability represents the capacity to modulate responses across six functional domains, including physical-sensory-motor integration, emotional-behavioral regulation, social-communicative effectiveness, academic-cognitive agility, psychological flexibility processes, and development of 21st-century skills in response to contextual demands while maintaining goal-directed action and value coherence.

Ecological engagement encompasses the capacity to understand complex system dynamics across multiple scales and participate effectively in collective action, supporting both individual flourishing and systemic health. Transformative creativity represents the capacity to generate novel solutions that transform existing constraints into opportunities while implementing innovations effectively in real-world contexts.

3.5 Case Study Validation

The transformation of an educational institution provides compelling empirical validation for transformative intelligence frameworks in educational leadership contexts. Upon assuming leadership responsibilities, the institution exhibited characteristics of organizational collapse, including unprofessional governance, toxic organizational culture, poor budgetary oversight, and corrupt practices.

The systematic application of transformative intelligence principles enabled complete organizational transformation within a three-year timeframe, achieving financial recovery from severe deficit to operational surplus, developing inclusive multicultural community structures replacing tribal governance patterns, implementing innovative pedagogical approaches improving academic outcomes, establishing full enrollment with waiting lists, and creating a thriving community center extending institutional influence beyond traditional educational boundaries.

4. Discussion

4.1 Theoretical Contributions

The research presents several significant theoretical contributions to educational leadership scholarship. First, the integration of psychological flexibility, technological innovation, and contemplative pedagogy within a unified framework addresses gaps in existing literature that typically treats these domains separately. Second, the conceptualization of transformative intelligence as a meta-systemic capacity provides a novel approach to understanding leadership effectiveness in complex environments.

The case study validation demonstrates practical applicability of integrated leadership frameworks in complex educational transformation contexts. The systematic application of transformative intelligence principles enabled simultaneous intervention across multiple organizational levels while maintaining coherent institutional vision and community relationships. This success contrasts sharply with traditional leadership frameworks that focus on isolated domains without addressing their dynamic interactions.

4.2 Integration of Human and Technological Dimensions

The research demonstrates successful integration of technological innovation with human-centered educational approaches, challenging traditional assumptions about competition between efficiency and relationship focus. The implementation of digital systems was successful because it was guided by clear educational principles and implemented through approaches that maintained focus on human relationships and educational quality.

This integration aligns with theoretical frameworks suggesting that artificial intelligence can enhance, rather than replace, human capabilities when implemented through human-centered design principles and comprehensive change management approaches (Bass & Riggio, 2006). The transformation demonstrates how strategic AI integration emphasizes predictive analytics supporting early intervention strategies while maintaining human judgment about individual student needs.

4.3 Implications for Educational Leadership Preparation

The research findings have profound implications for educational leadership preparation programs requiring fundamental reconceptualization of leadership development approaches. Traditional programs, which primarily focus on instructional improvement and organizational management, prove inadequate

for addressing contemporary challenges requiring crisis management capabilities, technological integration competence, multicultural community leadership, sustainable resource management, and psychological resilience during prolonged uncertainty.

Future educational leadership preparation must incorporate integrated competency development, combining theoretical understanding, practical skill development, psychological resilience building, and technological literacy within experiential learning contexts that simulate contemporary leadership challenges while providing mentorship and support for professional growth.

4.4 Limitations and Future Research

Several limitations require acknowledgment in interpreting research findings. The case study, while providing compelling evidence for transformative intelligence applications, represents a single institutional context that may not generalize across different cultural, economic, or organizational environments. The integration of multiple theoretical frameworks, while enabling comprehensive understanding, creates complexity in isolating specific causal mechanisms and identifying optimal intervention approaches.

Future research should include randomized controlled trials providing evidence for the effectiveness of transformative intelligence-based interventions while establishing causal relationships between participation in development programs and enhanced functioning across multiple domains. Multi-site implementation across diverse institutional contexts would provide evidence for generalizability and scalability while identifying contextual factors influencing implementation success.

Conclusion

This research presents transformative intelligence as a comprehensive framework that systematically integrates psychological flexibility, technological innovation, and contemplative pedagogy to address unprecedented challenges facing educational leadership in the 21st century. The theoretical framework demonstrates how meta-systemic capabilities enable educational leaders to navigate complex technological, social, and cultural transformations while preserving human-centered educational values and authentic community relationships.

The empirical validation through case study analysis provides compelling evidence for the practical applicability of transformative intelligence frameworks in complex organizational transformation contexts. The research advances educational leadership theory by bridging previously separate domains within a unified theoretical framework while providing both conceptual understanding and practical guidance for contemporary educational practitioners.

The implications extend beyond individual leadership development to encompass possibilities for systematic transformation of educational institutions and preparation programs capable of addressing global challenges while preserving local educational values and community relationships. Future educational leaders must embrace transformative intelligence as a foundational meta-competency, enabling navigation of technological acceleration, cultural diversity, environmental challenges, and social complexity characterizing contemporary educational environments.

The ultimate significance of transformative intelligence lies not merely in its contribution to educational effectiveness but in its potential to foster human flourishing in all dimensions, including individual well-being, collective wisdom, cultural creativity, and ecological sustainability. As educational leaders develop transformative intelligence capabilities, they contribute to the evolution of educational consciousness itself, participating in the ongoing project of realizing human potential in service of all life.

Workforce Stability in Healthcare: Key Predictors of Hospital Nurse Retention

***Veronika* Mozolová**[1,*]**, *Magdaléna* Tupá**[1]**, and *Monika* Gullerová**[1]

[1] Alexander Dubcek University of Trencin, Faculty of Socio-Economic Relations, Študentská 2, 911 50 Trenčín, Slovakia

Abstract

Research background: Securing an appropriately sized and qualified nursing workforce is a critical function of healthcare human resource management. The shortage of nurses poses a significant risk to the continuity of healthcare delivery; therefore, identifying the factors that influence nurses' decisions to remain in their current positions is essential for developing sustainable staffing strategies in hospitals.
Purpose of the article: The main goal of the study is to identify factors that exert a statistically significant influence on nurses' decisions to remain in or leave their current employment.
Methods: Binary logistic regression analysis was employed to examine the extent to which selected factors namely engagement, burnout, workload, specialization, hospital ownership, and professional experience serve as statistically significant predictors of nurses' intentions to remain in (coded as 1) or leave (coded as 2) their current employment. The analysis was based on primary data obtained through a structured questionnaire administered to a sample of 500 hospital nurses.
Findings & Value added: The binary logistic regression analysis identified four variables as statistically significant predictors of nurses' intent to remain in or leave their current employment, specifically engagement ($B = -0.382$; $p = 0.016$), higher burnout propensity ($B = 0.368$; $p = 0.027$), greater workload ($B = 0.328$; $p = 0.026$), and shorter duration of professional experience ($B = -0.476$; $p = 0.004$). In contrast, neither specialization nor hospital ownership status were identified as significant independent predictors. The overall model demonstrated statistical significance ($\chi^2 = 56.043$; $p < 0.001$) and explained between 50.6% and 55.5% of the variance in the decision to remain.
The findings underscore the importance of developing and implementing targeted management strategies that promote employee engagement, mitigate burnout, optimize workload distribution, and value professional experience. Such measures are essential for strengthening workforce stability within healthcare institutions.

1. Introduction

The work of hospital nurses is one of the most demanding professions, requiring not only a high level of expertise but also mental and physical resilience. The healthcare sector of today is facing new challenges and changes. Retaining nurses is crucial in stabilizing and ensuring the necessary healthcare workforce in hospitals.

Shortage of nurses, turnover or intention to leave have negative effect on organizational performance, resulting in financial and human resource losses (Neves et al., 2022). Nurses' intention to leave their job is a worldwide concern. Internal and external brain drain factors are the main reason for nurses' intention to leave their job (Ayalew et al., 2021).

1.1 Literature Review

The work environment and life satisfaction have an essential relationship in wellbeing and a determining influence on mental health and quality of life. The relevance of this connection is particularly evident in daily interactions and people's functionality in their work activities (Morales-García et al., 2024). The healthcare profession has been identified as one of the highest-risk occupations in terms of the likelihood and prevalence of negative psychological outcomes due to its challenging nature characterised by high levels of human contact, emotional demands and workload (Mazzetti et al., 2024).

Nurses in health-care environments, in daily contact with suffering patients, terminal situations, and impacting treatments, are one of the categories most exposed to the risk of work stress, turnover, dissatisfaction, and burnout (Ramaci et al., 2024). A positive work environment can enhance nursing safety and patient satisfaction while alleviating nurse stress. Conversely, a poor work environment can harm nurses' physical and mental health and compromise the quality of care (Gou et al., 2024). In addition, the job demands–resources (JD–R) theory discusses "work engagement in addition to burnout and considered burnout and work engagement to be mediators of the relation between job demands and negative outcomes (health problems), and job resources and turnover intention, respectively" (Zeng et al., 2022). In general, healthcare organizations struggle to deal with individual and working environment conditions related to moderate to high levels of employee stress, high-employee turnover rates, and an ageing workforce (Midje et al., 2024). The nurse staff is considered an integral part of the healthcare workforce and makes up approximately 60% worldwide. Optimal nurse staffing in hospital departments is a priority for most head nurses around the world. Adequate staffing levels in departments are essential for patient safety and the provision of high-quality healthcare (Yu et al., 2024). Sub-optimal nurse staffing characteristics can be observed during nursing shortages, such as inadequate staffing levels, longer working hours with overtime, and high turnover. Bae (2024) considers mandatory overtime to be a significant factor contributing to intent to leave (Bae, 2024). Employee retention is conceptually the opposite of turnover. It can be defined as the ability to retain workers within the organization where they are employed for prolonged time, typically one year or more. The key question for healthcare managers and policymakers is understanding which factors affect, directly or indirectly, the retention of healthcare workers, and how to better exploit such factors to maximize employee retention (Moscelli et al., 2025). Sustainability occurs when resources are used as efficiently as possible, without compromising the quality of care for patients (Hossny, 2022). Neves et al. (2022) maintain that the factors affecting nurses' intention to leave include work environment, emotional exhaustion, practice safety, and shortage of staff. Inadequate staffing, including an increased workload in work environments unfavourable to nursing practices, usually motivates professionals to leave. Burmeister et al. (2019) state that nurses' intention to leave is significantly influenced by the increased perception of inadequate staffing in the department and lower job satisfaction. Alenazy et al. (2023) concluded that the turnover rate of nurses can be lowered by job satisfaction of other members of the nursing team, their productivity, and career intentions.

1.2 The scientific concept of Job Demands - Resources theory

Fundamental to the JD-R model, is the proposition that any occupation has contextual risk and protective factors that can be classified as job demands or resources. Job demands, defined as the physical and psychological stressors inherent in a work role, can trigger a process where employees experience sustained psychological and physiological drain, explicitly linked to the health impairment process (Parkinson-Zarb et al., 2025). Job resources and demands have a multiplicative impact on emotional exhaustion and job satisfaction (Awwad et al., 2022). The Job Demands–Resources (JD-R) theory is grounded in the conceptualization of burnout syndrome, characterized by two core components: (1) excessive job demands that contribute to employee exhaustion, and (2) a lack of adequate job resources that leads to diminished work engagement (Della Bella et al., 2022; Paterson et al., 2024). In the JD-R theory, the authors define job demands as physical, psychological, social, or organizational aspects of the job that require sustained physical or psychological (cognitive and emotional) effort or skills and are therefore associated with certain physiological or psychological costs (Vachhrajani et al., 2022; Meng et al., 2023; Marzocchi et al., 2023; Xie et al., 2024). Job demands are defined as organizational requirements that require physical and psychological efforts for fulfilment. If individuals perceive job demands outweighing job resources, they will experience physical and cognitive costs in form of JS, exhaustion, and burnout (Sousan et al., 2022). According to Udushirinwa et al. (2022), the risk of high stress and imbalance between high job demands and low job resources exists in almost every workplace. Moreover, they state that

healthcare workers are exposed to significant deficits in job resources (Udushirinwa et al., 2022). The phenomenon is made up of two components: a problem (e.g. resource/time scarcity) and a process (clinical decision-making to prioritize care) (Stemmer et al., 2022). Burnout consists of two components, named exhaustion and disengagement from work. The exhaustion dimension refers to feelings of physical fatigue and overload with relation to work, while the dimension of disengagement refers to the distance from work and negative attitudes toward their own work (Wójcik et al., 2022).

1.3 Burnout and Work-Related Health Problems

The World Health Organization (WHO) recognizes occupational burnout as a result of chronic stress experienced in the workplace consisting of three dimensions: the feeling of loss, negative feelings concerning work and the mental distance toward it, as well as reduced professional effectiveness (Wójcik et al., 2022). Job burnout is seen as the antithesis of work engagement, a state characterized by vigour, dedication, and absorption (Urban et al., 2024). Burnout is one of the most studied psychosocial syndromes in the workplace in recent years, typically shouldered by service professionals (Nonnis et al., 2024). In Europe, every forth worker experience that their health is at risk due to conditions of working life. Burnout is defined as a persistent, negative, work-related state of mind in 'normal' individuals that is primarily characterized by exhaustion. The state of mind is accompanied by distress, a sense of reduced effectiveness, decreased motivation, and the development of dysfunctional attitudes and behaviours at work (Frögéli et al., 2022). Depersonalization is reflected in treating patients as objects rather than human beings, leading to a callous attitude towards patients (Wei et al., 2024). Work-related health challenges and adverse health outcomes, such as musculoskeletal disorders, stress, and burnout, are increasing within occupational health worldwide (Thapa et al., 2022).

Research gap: *Based on a literature review, to identify the factors that, within the context of the JD-R theory, predict retention or turnover, and to assess their strength among hospital nurses.*

2. Methods

The primary goal of the study is to use binary logistic regression to determine which variables have a statistically significant impact on nurses' decisions to stay in their current employment or to leave.

Partial goals:

Step 1: Review of scientific literature – the literature analysis is based on sources from the Web of Science database, with articles published in journals indexed in the SSCI.

Step 2: Operationalization of variables and determination of measurement methods – this step involves selecting variables identified through the literature review. The chosen variables are measured using a Likert scale. Responses reflect the degree of agreement with specific statements on a 1–5 scale. The variables of satisfaction and sustainability are measured and recoded as follows: strongly disagree – 1; disagree – 2; neutral – 3; agree – 4; strongly agree – 5. The variable of engagement is assessed and recoded using the following scale: never – 1; rarely – 2; don't know – 3; often – 4; always – 5.

Step 3: Model testing through binary logistic regression – In this phase, binary logistic regression analysis is used to examine which independent variables have a significant impact on the defined dependent variable.

Step 4: Interpretation of binary logistic regression results – verification of hypotheses and assumptions based on the results of variable measurement.

Step 5: Developing recommendations for healthcare institutions in Slovakia – these recommendations will be based on the findings from the model that identifies predictors of the intention to leave.

Application of the statistical method:

Binary logistic regression is a technique employed to examine the relationship between a binary dependent variable and one or more independent variables, which may be either categorical or continuous. This method utilizes the logistic (sigmoid) function to estimate the probability that the dependent variable falls into one of two categories, typically represented as 0 or 1.

Hypotheses:

H1: There is a statistically significant relationship between engagement and the intention to leave.

H2: There is a statistically significant relationship between burnout propensity and the intention to leave.

H3: There is a statistically significant relationship between perceived workload and the intention to leave.
H4: There is a statistically significant relationship between the nurses' attained specialized education and the intention to leave.
H5: There is a statistically significant relationship between the hospital ownership status and the intention to leave.
H6: There is a statistically significant relationship between the number of years worked and the intention to leave.

3. Results

The purpose of the binary logistic regression was to determine which variables have a statistically significant effect on nurses' decisions to stay in their positions or to leave. The dependent variable was binary, coded as 1 for remaining in their current employment and 2 for intending to leave. The model incorporated six predictors: engagement, burnout propensity, workload, specialized education, hospital ownership status, and the length of nursing experience.

Table 1. Block 0: Initial block of the regression model

Classification Table[a,b]							
	Observation		Prediction				
			Sustainability		Percentage Correct		
			1	2			
Step 0	Sustainability	1	367	0	100		
		2	133	0	0		
	Overall percentage				73.4		
Variables in the Equation

	Overall Statistics			**54.176**	**6**	**0.000**	

Source: Authors' elaboration, 2025

Baseline model (step 0)

In the baseline model (no predictors), the constant is B = -1.015 ($p < 0.001$), which indicates that, in the absence of independent variables, the likelihood of nurses remaining employed is significantly higher than that of leaving. The exponential coefficient (Exp(B) = 0.362) implies that the odds of a nurse leaving are 0.362 times the odds of remaining in her current position. The overall classification accuracy of the null model is 73.4%, with all cases predicted as remaining, resulting in 100% accuracy for the remain category and 0% for the leave category.

The Variables not in the Equation table revealed that multiple variables demonstrated statistical significance in univariate analyses, including engagement ($p < 0.001$), burnout propensity ($p < 0.001$), workload ($p < 0.001$), nursing experience ($p < 0.001$), and specialized education ($p = 0.002$). Conversely, hospital ownership status and gender were not found to be significant predictors.

	Overall Percentage				76.0

Variables in the Equation							
		B	S.E.	Wald	df	Sig.	Exp(B)
Step 1	**Variable**						
	Engagement	-0.382	0.159	5.790	1	0.016	0.683
	Burnout Propensity	0.368	0.166	4.880	1	0.027	1.444
	Workload	0.328	0.148	4.945	1	0.026	1.389
	Specialized Education	0.284	0.268	1.121	1	0.290	1.328
	Hospital Ownership Status	0.246	0.244	1.019	1	0.313	1.279
	Nursing Experience	-0.476	0.165	8.308	1	0.004	0.621
	Constant	-1.173	1.202	0.953	1	0.329	0.309

Source: Authors' elaboration, 2025

Resulting Model (step 1)

After incorporating all variables into the regression model, there was a statistically significant increase in its predictive accuracy (Omnibus test: $\chi^2 = 56.043$; df = 6; $p < 0.001$), demonstrating that the model is appropriate for predicting nurses' decisions. The model also exhibited improved pseudo-R^2 values (Cox & Snell $R^2 = 0.506$; Nagelkerke $R^2 = 0.555$), explaining between 50.6% and 55.5% of the variance in the decision to remain in current employment. Additionally, the Hosmer-Lemeshow test value was non-significant ($p = 0.857$), indicating a good fit between the model and the actual data.

The model's classification accuracy increased to 76.0%. It correctly classified 96.5% of respondents who indicated they would remain and 19.5% of those who expressed their intention to leave. Although the sensitivity for the leaving category remains relatively low, this marks a notable improvement compared to the null model.

Binary logistic regression takes the form:

$$P(leaving\ the\ current\ employment) = 1 / (1 + e\hat{}(-z))$$

$$where:$$

$$z = -1.173 - 0.382 \cdot engagement + 0.368 \cdot burnout + 0.328 \cdot workload$$

$$+ 0.284 \cdot specialization + 0.246 \cdot hospital\ ownership\ status - 0.476 \cdot experience$$

Table 3. Interpretation Table

Variable	B	Sig.	Exp (B)	Interpretation
Engagement	-0.382	0.016	0.683	Higher engagement **reduces the likelihood of leaving** (by appr. 31.7%).
Burnout Propensity	0.368	0.027	1.444	Higher burnout propensity **increases the likelihood of leaving** (by appr. 44.4%).
Workload	0.328	0.026	1.389	Higher perceived workload **increases the likelihood of leaving** (by appr. 38.9%).
Specialized Education	0.284	0.29	1.328	Not significant – does not have a statistically significant effect ($p > 0.05$).
Ownership Status	0.246	0.313	1.279	Not significant – hospital ownership does not influence turnover.
Nursing Experience	-0.476	0.004	0.621	Longer work experience **reduces the likelihood of leaving** (by appr. 37.9%).

Source: Authors' elaboration, 2025

Interpretation of regression coefficients:

The table shows that four out of six predictors were of statistical significance ($p < 0.05$): Engagement had a negative regression coefficient ($B = -0.382$; $p = 0.016$; $Exp(B) = 0.683$), which means that with each one-unit increase in engagement, the likelihood of leaving decreases by approximately 31.7%. This result supports the hypothesis that higher job engagement has a protective effect against turnover intentions. The burnout propensity had a positive and statistically significant effect ($B = 0.368$; $p = 0.027$; $Exp(B) = 1.444$). This indicates that with a one-unit increase in burnout score, the likelihood of leaving increases by 44.4%. The outcome is consistent with the literature sources identifying burnout as a significant factor in the turnover of healthcare personnel. Workload was also found to be a significant positive predictor ($B = 0.328$; $p = 0.026$; $Exp(B) = 1.389$). Higher perceived workload leads to a 38.9% increase in the likelihood of leaving, highlighting the need for managerial intervention to regulate workload. Nursing experience proved to be a significant negative predictor ($B = -0.476$; $p = 0.004$; $Exp(B) = 0.621$), with each additional year of experience reducing the likelihood of leaving by approximately 37.9%. This relationship suggests that more experienced nurses are more likely to stay.

In contrast, specialization education ($p = 0.290$) and the hospital ownership status ($p = 0.313$) did not show statistical significance in the multivariate model, suggesting that, after controlling for other variables, these factors by themselves do not have a significant impact on the decision to stay. Generating the ROC curve made it possible to determine that the model has excellent discriminative ability (AUC value of 0.822). The VIF values of the individual factors in the model indicate that the variables do not overlap, and therefore the regression coefficients can be considered reliable. The ROC curve analysis demonstrated that the model possesses excellent discriminative power (AUC value of 0.822). Additionally, the VIF values for the individual factors indicate minimal multicollinearity, supporting the reliability of the regression coefficients.

4. Discussion

The study provided valuable insights into the issue of nurse turnover in Slovak hospitals, a threat to the sustainability of hospital staffing. By applying binary logistic regression, the research identified major predictors that significantly affect nurses' decisions to either stay in or leave their jobs. The results demonstrate the strong influence of psychological and work-related factors, including engagement, burnout, and perceived workload, along with the length of professional experience. However, some of the anticipated predictors such as specialized education and hospital ownership status were not found to be statistically significant in the model. Therefore, this section will focus on a deeper interpretation of the findings, their potential practical implications, and possible directions for future research in this important area. The findings from the literature review conducted by Montayre et al. (2023) underscore the necessity of adopting a holistic approach to mental health interventions, emphasizing the importance of supporting both the psychological and physical well-being of nurses. This underscores the imperative to implement comprehensive strategies rather than isolated, piecemeal interventions. Similarly, research by

Zhang et al. (2024) highlights the critical role of fostering a supportive work environment within the nursing profession. Facilitating work-life balance has been shown to enhance psychological resilience and improve job satisfaction among nurses. Moreover, Moore et al. (2024) assert that prioritizing the mental well-being of hospital nurses is fundamental to establishing a stable and proficient nursing workforce capable of addressing evolving healthcare challenges. Healthcare organizations that actively promote nurse engagement in specialized mental health support programs are more likely to achieve optimal overall well-being among their staff.

Hospitals that prioritize enhancing nurses' engagement may anticipate a decline in turnover rates, thereby contributing to a more stable workforce. Ren et al. (2024) investigated engagement within the context of working conditions, emphasizing the relevance of the two-factor theory. Their findings indicate that motivational factors play a critical role in fostering work enthusiasm. Furthermore, Higher perceived social support correlated with greater work engagement, likely due to the mitigation of burnout and stress.

The duration of clinical experience among nurses has been identified as a significant predictor of a reduced intention to leave their current employment. Nurses with extended tenure at the same healthcare institution may demonstrate lower motivation to seek alternative positions, likely influenced by factors such as impending retirement and the job security afforded by long-term service. Consequently, particular attention should be directed towards early-career nurses, who are at a heightened risk of turnover. Sugawara et al. (2023) reported that self-compassion contributes to lower levels of stress and burnout among nurses, while simultaneously enhancing their work engagement. While workplace conflicts and excessive workloads were found to exacerbate burnout, engaging and meaningful work served to mitigate it. Notably, role conflict exhibited a paradoxical effect, being associated with decreased burnout and increased engagement. Although burnout was linked to a higher intention to leave, engagement did not significantly affect this intention. Therefore, fostering self-compassion among younger nurses may prove beneficial in reducing both stress and turnover intentions within this vulnerable group.

Morales-García et al. (2024) point to the need to implement strategies that strengthen nurses' work engagement and job security while effectively managing job demands to prevent depression. These findings also highlight the importance of the Job Demands-Resources (JD-R) theory for understanding and improving nurses' job satisfaction and performance. The findings from the study investigating predictors of nurse retention offer valuable practical implications for interventions grounded in the JD-R (Job Demands-Resources) theory. Specifically, the results indicate that strategies focused on enhancing job resources such as fostering engagement, cultivating experience, and strengthening loyalty among veteran nurses as well as mitigating job demands through workload management and burnout prevention may serve as effective approaches to reducing nurse turnover.

Conclusion

The study aimed to identify variables that have a statistically significant impact on hospital nurses' decisions to either stay in their positions or leave. To achieve this, binary logistic regression was employed, with the dependent variable coded as a binary outcome (1 for staying, 2 for intention to leave). The model included six predictors: engagement, burnout propensity, perceived workload, level of specialized education, hospital ownership status, and the length of nursing experience.

The regression analysis results indicated that four of the predictors examined achieved statistical significance ($p < 0.05$). Nurse engagement exhibited a negative effect on the intention to leave, suggesting that increased engagement is linked to a reduced likelihood of turnover ($Exp(B) = 0.683$). This finding supports H1 hypothesis, which assumed a significant relationship between engagement and intention to leave. Next, burnout propensity and perceived workload showed positive and statistically significant effects, with higher burnout levels ($Exp(B) = 1.444$) and greater workload ($Exp(B) = 1.389$) associated with an increased probability of intending to leave. Consequently, H2 and H3 hypotheses predicting significant relationship between burnout, workload, and intention to leave were confirmed.

Another noteworthy result was the significant negative influence of nursing experience; each additional year of professional practice reduced the likelihood of leaving ($Exp(B) = 0.621$), suggesting greater stability among more experienced nurses. This confirmed H6 hypothesis, which stated a statistically significant relationship between the number of years worked and intention to leave.

In contrast, the variables representing specialized education and hospital ownership status were not identified as statistically significant predictors of nurses' decisions to stay within the multivariate logistic regression model. Nonetheless, the model demonstrated strong discriminative performance, as evidenced

by an area under the curve (AUC) of 0.822. Additionally, variance inflation factor (VIF) analysis indicated no substantial multicollinearity among the independent variables, thereby enhancing the robustness and interpretability of the regression coefficients. Accordingly, the findings support the acceptance of H4 and H5 hypotheses, indicating no statistically significant association between either specialized education or hospital ownership status and nurses' intention to leave.

In conclusion, nurse engagement and the duration of professional experience are key factors contributing to workforce retention in hospital settings, whereas elevated levels of burnout and excessive workload emerge as critical risk factors associated with increased turnover intentions.

The findings of this study offer robust empirical validation for the two central mechanisms articulated by the JD-R theory. Specifically, engagement conceptualized as a job resource was shown to exert a protective, motivational effect, with higher engagement levels significantly reducing the likelihood of nurses intending to leave their positions. Engagement (a job resource) demonstrated a strong motivational process, as higher engagement levels were associated with a lower likelihood of leaving. Conversely, burnout propensity and perceived workload (job demands) go hand in hand with the intention to leave.

By situating these dynamics within the hospital nursing context, the study underscores the explanatory power and practical utility of the JD-R framework. It highlights how distinct job-related resources and demands contribute to retention or attrition decisions among nurses, thereby offering a theoretically grounded foundation for the development of targeted and evidence-based strategies aimed at sustaining a stable nursing workforce.

Recommendations and Proposals for Hospital Management with an Emphasis on Nurse Retention

Drawing on the study findings, the following recommendations are proposed for hospital management to promote the retention of nursing personnel: (1) Enhancing nurse engagement: It is advisable to adopt strategies that improve the work environment, foster nurses' autonomy within their professional roles, ensure effective communication and transparency, and facilitate opportunities for continuous professional development. Conducting periodic assessments of job satisfaction and engagement can yield critical insights to inform and refine targeted intervention efforts. (2) Elevated burnout levels have been identified as a significant predictor of nurses' intention to leave their current employment. Consequently, the implementation of proactive burnout prevention initiatives and effective management strategies is imperative. Such interventions may encompass workshops and training programs centred on stress reduction, well-being enhancement, time management optimization, and resilience development. It is also important to foster a culture in which nurses feel safe, are allowed to discuss their challenges openly, and receive necessary support from management and colleagues. (3) The finding that higher perceived workload significantly increases the likelihood of turnover highlights the need for a thorough analysis and optimization of work processes and staffing levels. Management should consider options for task redistribution, ensuring an adequate number of staff in relation to patient needs, and implementing efficient scheduling systems. The introduction of technological solutions to reduce nurses' administrative burden may also contribute to lowering their overall workload. (4) The pronounced impact of the length of professional experience suggests that more experienced nurses serve as a stabilizing factor within the hospital. Consequently, fostering a work environment that recognizes and appreciates their expertise is essential. Support strategies may encompass the implementation of mentorship programs for less experienced staff, active inclusion of experienced nurses in organizational decision-making, and the provision of continuous professional development and career progression opportunities.

Although specialized education and hospital ownership status were not identified as statistically significant predictors in this model, their potential influence should not be entirely disregarded. t is possible that indirect effects or interactions with other variables, not captured in this study, play a role. Consequently, ongoing monitoring of these factors is advised, alongside their integration within a comprehensive human resource management framework. Investing in strategies that enhance nurse engagement, prevent burnout, optimize workload, and support experienced personnel constitutes a critical approach for hospital administrators seeking to mitigate turnover and maintain a stable, motivated nursing workforce. Continuous evaluation of key performance indicators and the dynamic adjustment of interventions based on empirical data are imperative to ensure the sustained retention of nursing staff within hospital environments.

Abstract

Research background: The year 2022 marked a watershed moment for the Slovak Republic, influenced by the lifting of COVID-19 restrictions, the onset of the conflict in Ukraine, and the beginning of an energy crisis affecting multiple countries. These events significantly impacted all sectors of the national economy, including education. This paper examines strategic measures implemented to mitigate the energy crisis's effects on schools and school facilitates in Slovakia. In response to rising energy costs, the Ministry of Education, Reasearch, Development and Youth of the Slovak Republic allocated substantial budgetary resources-exceeding EUR 12 million in 2022 and EUR 75.5 million in 2023-to compensate schools and school facilities for increased energy expenses. To ensure efficient and economical use of these funds, a comprehensive data collection process was established to verify the accuracy and validity of energy consumption reports submitted by schools.
Purpose of the article: This paper analyses the development and implementation of control mechanisms that enable monthly verification of energy consumption and unit prices, ensuring transparent and accountable state budget funding.
Methods: Particular emphasis is placed on the data collection, validation, and analysis processes, highlighting the importance of transparency and inter-ministerial and other relevant institution cooperation.
Findings & Value added: The findings demonstrate how systematic data evaluation can improve school financing and support the efficient operation of school facilities even during crises, thereby safeguarding conditions for quality education. The paper concludes by discussing prospects for enhanced inter-ministerial and other relevant institution collaboration to foster more effective educational financing solutions in the future.

Keywords: Energy crisis, Energy costs, Schools and school facilities, Educational financing

JEL classification: H52, H70

1. Introduction

The energy crisis, which has intensified significantly in recent years due to global geopolitical and economic factors, has had a major impact on the operating costs of all economic actors, including public and educational institutions (Xu et al., 2022; Paone and Bacher, 2018). Increased energy prices, including electricity and heating, place a significant financial burden on schools, threatening their ongoing operations and the quality of education provided (Pinnington, 2025; Bertone et al., 2018). As public institutions, schools are often dependent on government funding, which may not always adequately reflect rapid changes in energy costs (Anglum, Shores and Steinberg, 2021; Delardas and Giannos, 2022). In this context, the role of ministries of education and other government bodies in providing adequate financial support and implementing effective funding mechanisms to enable schools to cope with

[*] Corresponding author: lubomir.nebesky@vsemba.sk

increased operational costs is crucial (Anessi-Pessina et al., 2020; Bellei and Contreras, 2024; Sulasmi, Prasetia, and Rahman, 2023).

In addition to direct financing of operating costs, the literature also highlights the importance of investing in energy efficiency in school buildings, which can reduce costs and contribute to environmental sustainability in the long term (Chaer et al., 2025; Wang et al., 2022). The use of intelligent energy management systems and the implementation of renewable energy sources are additional opportunities to reduce schools' dependence on unstable energy prices (Benkhalfallah, Kouah, and Ammi, 2023; Taylor et al., 2008). This article focuses on an analysis of available financing mechanisms and measures that schools can use to deal with the energy crisis, with an emphasis on the role of government authorities in providing support.

The aim of the paper is to determine how assistance was provided to schools to eliminate the negative impacts of the energy crisis. This paper analyses the development and implementation of control mechanisms that enable monthly verification of energy consumption and unit prices, ensuring transparent and accountable state budget funding.

In Slovakia, there was a threat of schools closing again after the COVID-19 pandemic (Stoličná and Barjaková, 2023), but the Ministry of Education, Research, Development and Youth of the Slovak Republic (hereinafter referred to as “Minedu”) rejected this way of solving the energy crisis and proceeded to provide funds to compensate for the increased energy expenses for schools and school facilities. The Minedu decided to quickly provide targeted assistance to schools financed from the state budget, which included primary, secondary and special schools, as well as kindergartens with legal personality. There were 3 relevant ministries to provide the solution, namely the Minedu, the Ministry of Finance, the Ministry of Economy, which provided its own scheme of support to economic entities, but with some limitations that were insufficient for the support to schools (Economy, 2025).

In order to ensure efficient and effective use of budget resources, it was necessary to establish the control mechanisms applied before allocating funds to schools. Relevant data for verification were unit price and monthly consumption of commodities. The Ministry of Economy reported that it was not possible to check the specified range of data if it exceeded their aid scheme. For this reason, the Minedu had to develop its own control mechanisms to ensure the efficient use of the public funds, verifying the relevance of the data through 2 entities under the competence of the Ministry of Economy for the commodities gas and electricity, as energy is provided to schools by approximately 150 suppliers, which in the case of verifying the data directly with them could significantly prolong the whole process of control and fund´s distribution.

1.1 Literature Review

Research on energy cost financing in schools shows that there is a wide range of financial instruments that schools can use to reduce their operating costs during energy crises. Among the most commonly mentioned are state grants, donations, bonds, and leasing programs that allow for financing energy upgrades without an immediate financial burden on a school's budget (U. S. Department of Energy, 2020; Alam et al., 2019; Jackson, Wigger, and Xiong, 2021). Chaer et al. (2025) emphasize that effective energy management in school buildings involves not only technical measures, but also organizational changes and staff training. Almasri et al. (2024) and Rosato et al. (2019) summarize the complex relationship between energy efficiency and renewable energy systems within educational institutions.

Bertone et al. (2018) identify the main barriers to the implementation of energy savings, which include lack of financial resources, administrative burden and low awareness of available funding opportunities. Similarly, Pinnington (2025) and Delardas and Giannos (2022) point out that volatility in energy prices complicates school budget planning, which requires flexible and fast funding from the state.

Investments in renewable energy and smart energy management systems are a promising path to long-term sustainability, according to Wang et al. (2022) and Benkhalfallah, Kouah and Ammi (2023). These measures not only reduce costs but also improve the environmental profile of schools, which is in line with the Sustainable Development Goals (SDGs) globally.

Sweatman and Managan (2010) and Bellei and Contreras (2024) emphasize the role of government institutions, particularly ministries of education, in developing policies and providing financial support

that enable schools to respond to the energy crisis. Sulasmi, Prasetia and Rahman (2023) and Lee, Shores and Williams (2022) extend this perspective to the need for schools to build organizational resilience, which includes the ability to adapt to unexpected energy shocks through effective management and financing.

Life-cycle economic analyses of energy saving investments in schools (Hu, 2019; Stocker, Tschurtschenthaler and Schrott, 2015) confirm that despite the initial costs, these projects generate significant savings in the long term. It is therefore essential that government funding supports not only short-term compensation for increased costs, but also investment in sustainable solutions (Taylor et al., 2008; Hu, 2019).

2. Methods

Data were collected through controlled data collection from schools that were allowed to voluntarily complete an online survey form. The questionnaire collected basic information about the school and relevant information for the evaluation of the input data on energy consumption (electricity, gas, solid fuel), financial costs associated with energy consumption and the identification of the points of consumption (PODs and EIC codes). The collected data were systematically recorded in a database created in the Microsoft Excel programming environment, which allowed for efficient filtering, processing, consistency checking and further data analysis. Prior to the actual analysis, the following steps were performed:

1. Detection and elimination of random errors: data were checked for obvious errors (e.g. incorrect number formats, duplicates, unit mismatches etc.).
2. Data validation: Data entered by individuals where systematic errors or inconsistencies were found were extracted and, where necessary, removed.
3. Completeness check: All mandatory fields were checked for completeness and correct structure.
4. Data validation - the following procedures were carried out to ensure the quality and validity of the data:
    a) Logical check: Verification of the logical consistency of the data (e.g. impossibility of negative consumption, unusually high payments relative to average consumption, etc.).
    b) Cross-validation of data: comparison of data obtained with direct verification with suppliers (energy consumption).
    c) Application of internal rules: Setting and application of control conditions that had to be met (e.g. range of maximum and minimum energy consumption for a certain period, energy unit price values in line with market prices in the period under review, consistency between type of point of consumption and consumption, etc.).

Subsequently, data analysis and evaluation were performed. Statistical and analytical methods were applied to evaluate the data:

1. Descriptive statistics: calculations of average, minimum and maximum values of consumption and energy costs.
2. Outlier detection: identification of outliers or trends that would indicate anomalies.
3. Data segmentation: aggregation of data according to predefined criteria such as type of commodity (electricity, gas, solid fuels), type of financial assistance received (energy donations), region of operation of the school.

Data collection was conducted in several rounds. Each round of data collection involved up to 2,000 eligible applicants, the data was always filled in by the parent school and for all its components and sites, i.e. this number covers a realistically larger number of schools and school facilities. After each round of evaluation, the results were processed and submitted to the Ministry of Finance of the Slovak Republic together with the request for a budget measure. The results of each round were subsequently published on the official website with notification to schools. In cases of uncertainties or inconsistencies in the data, communication back to the schools was ensured. The purpose of verifying the data directly with the schools was to clarify the data and to ensure the correctness of the calculation of the financial aid intended to compensate for increased energy costs during the energy crisis.

3. Results

Compensation for increased energy costs covered a number of areas:

I. The 2022 arrears reimbursement (Minedu, 2023a)

The 2022 arrears reimbursement was intended for schools funded directly from the state budget. An electronic online form was launched on 26 January 2023 through the energy.iedu.sk website and was closed on 31 August 2023.

A total of 6 rounds were evaluated with a request for additional funding exceeding EUR 12 million. Under this aid, funding of over EUR 5.8 million was granted to schools and educational establishments after the introduction of controls.

The total amount of the arrears reimbursement was requested from the Ministry of Finance and delivered to the schools based on a completed form.

Controls that were put in place when assessing arrears for 2022:

- the amount of arrears/overpayment cannot be higher than the total cost for 2022,
- the total annual cost including VAT and distribution and other charges for all commodities combined was lower than the amount provided for energy financing in 2022,
- the unrealistic unit price of the commodity,
- the amount of arrears in relation to the total cost is too high,
- the request for the refinancing was less than 100 €,
- the data was not entered on the basis of the annual billing invoices, the identification data of the consumption points (EIC/POD codes) and the annual energy consumption,
- the requests have already been granted in previous refinancing rounds.

II. Full financial aid in 2023 (Minedu, 2023b)

The full financial aid for the increased energy rates in 2023 was intended for schools financed directly from the state budget (primary, secondary, special schools and all their units) under the jurisdiction of all founders.

The electronic form was launched on 1 March 2023 via the web. A total of 6 rounds were evaluated for schools financed directly from the state budget with a request for additional funding of more than EUR 75.5 million. Under this aid, funding of over EUR 41.7 million was granted to schools and educational facilities following the implementation of the controls.

The controls put in place for the evaluation were the same as in the previous case.

Aid scheme:

1. Financial aid for schools was provided by the Minedu as follows:
   - 80 % of eligible costs for electricity and natural gas consumed (commodity price excluding VAT and charges) as follows:
   - in case of natural gas, eligible costs were the product of the increase in the unit price for the commodity above EUR 99/MWh (capped price) and the consumption in MWh,
   - in case of electricity, eligible costs were the product of the increase in the unit price for the commodity above EUR 199/MWh (capped price) and the consumption in MWh.
2. Financial aid for schools supported by the Ministry of Finance
   - 20% of the eligible costs for electricity and natural gas consumed (commodity price excluding VAT and charges), in case the unit price of the commodity exceeded the capped price - electricity (199 €/MWh,) and gas (99 €/MWh) as follows:
   - in case of natural gas, the eligible costs were the product of the increase in the unit price for the commodity above €99/MWh and the consumption in MWh,
   - in case of electricity, the eligible costs were the product of the increase in the unit price for the commodity above €199/MWh and the consumption in MWh.

If the unit price of the commodity - electricity, natural gas both exceeded and did not exceed the capped price (199 €/MWh, resp. Minedu proceeded to compare the cost of the unit price of the commodity for 2023 with 2022 and the request to the Ministry of Finance was also subject to the financial support for schools, which will be the product of the year-on-year increase in the unit price of the commodity in € and the consumption in MWh. The amount of fees and VAT was added to the above eligible costs in points 1. and 2. (A+B).

All of the above calculations were made by the Minedu from data collected via an electronic form.

After the finalization of the electronic data collection “Full financial aid in 2023” for the period January-October 2023, when the control mechanisms were in place (checking of monthly consumption by EIC/POD codes, etc.), the requests of schools and state school establishments for the co-financing of the expected energy costs in the period October-December 2023 were additionally aggregated. The requests for co-financing under this aid amounted to more than EUR 21.0 million and more than EUR 20.8 million were granted through the ‘conciliation procedure’ without additional checks on monthly consumption based on EIC/POD codes.

III. Financial aid for kindergartens with legal personality in 2023 (Minedu, 2023c)

Financial aid for increased energy rates in 2023 was also intended for kindergartens with legal personality under the jurisdiction of municipalities and non-state founders.

The electronic form was launched on 15 March 2023 via the website and closed on 30 October 2023.

In total, 7 rounds were evaluated with a request for additional funding amounting to over EUR 500.000. Over EUR 400.000 of funding was granted under this support after the checks were put in place. The checks that were put in place during the evaluation were the same as in previous cases.

Aid scheme:

The financial aid was aimed to deliver funds to kindergardes with legal personality in the amount of 80 % of the eligible costs for electricity and natural gas consumed (commodity price excluding VAT and charges) as follows:

- in case of natural gas, the eligible costs were the product of the increase in the unit price for the commodity above EUR 99/MWh and the consumption in MWh,
- in case of electricity, the eligible costs were the product of the increase in the unit price for the commodity above EUR 199/MWh and the consumption in MWh.

IV. Financing of increased rents in 2023 (due to the increase in energy prices) (Minedu, 2023d)

Minedu also prepared the support for schools that are located in rented spaces and, in addition to the rent, pay the landlord the costs of energy consumed in the rented space. The founders of these schools could apply for an increase in payments due to the increase in energy prices through the “Conciliation procedure”, which was announced for this specific purpose.

A total of 6 rounds were evaluated with a request for additional funding of over EUR 800.000. Over EUR 450.000 has been provided under this aid.

The following criteria were taken into account when assessing the requests from schools/school facilities:

- accuracy and completeness of the completed form,
- assessment of the feasibility of the increase in rent including utilities - if the rent including utilities for the month in question represents more than 25% of the 2022 amount, funding was only proposed after an individual assessment of the utility bills,
- if the landlord had applied for a support from the Ministry of Economy, the amount of the proposed funding was reduced,
- funding was not provided if a school with the same commodity and off-take points also entered into other schemes of aid and funding was proposed up to a maximum of the recommendation of the regional office of the school administration.

V. Conciliation procedure - Costs of school operating swimming pools (Minedu, 2023e)

The Minedu also addressed assistance to schools operating school swimming pools as there were significant cost increases to run them, with similar rules in place and funding being provided in two rounds with controls in place.

Primary art schools, language schools and school facilities, that were not part of schools were not included in aid provided by Minedu but could use the energy grant for public administration through the Ministry of Economy (Economy, 2025).

Table 1. Overview of funding requested and provided under each type of financial support for 2023 by evaluation rounds

Source: own processing based on data from Minedu (2023a, 2023b, 2023c, 2023d, 2023e)

Table 1 summarises the requested and provided funding under the five types of financial assistance for each of the 2023 evaluation rounds. The types of financial assistance are indicated by the Roman numerals I to V, where:

I. The 2022 arrears reimbursement,
II. Full financial aid,
III. Financial aid for kindergartens with legal personality,
IV. Financing of increased rents in 2023 due to the increase in energy prices,
V. Conciliation procedure - cost of operating the school pools.

The data shows that when the first rounds of financial aid were launched, the application error rate from schools was relatively high. This may have been due to both random errors in filling in the applications, but also to the limited knowledge of the issues and the methodology that schools had to learn in a short time. The situation is very much reminiscent of the pandemic crisis, when schools and educational facilities had to adapt to the new administration and crisis measures.

However, a positive trend can be observed in subsequent rounds - an increase in the success (approval) rate of requests, which may be due either to a gradual improvement in the quality of the applications submitted or to a change in the evaluation and approval methodology.

While in Round 1 the approval rate was only 34%, in the following rounds (especially in Rounds 6 and 7) this rate increased up to 65% and 99% respectively.

This increase may be the result of better information to schools, the introduction of supportive guidelines, but also of formal adjustments in the evaluation processes. At the same time, it should be taken into account that over time there may have been a slight reduction in the control mechanisms, or administratively simpler and faster approval of applications - especially in rounds where there was increased pressure to distribute funds quickly.

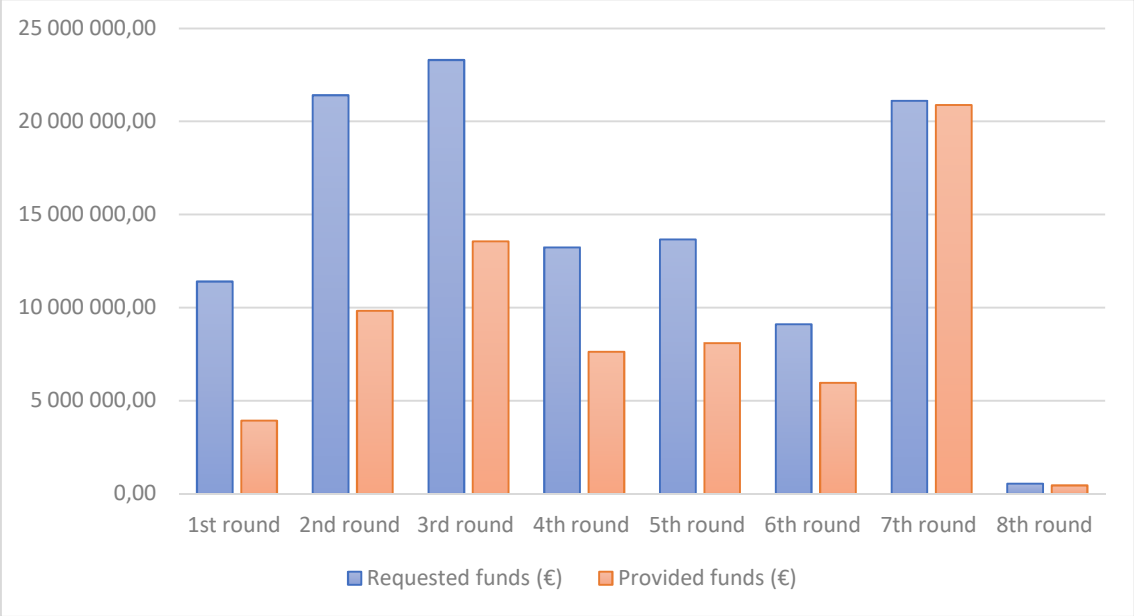

Figure 1. Graphical interpretation of requested and provided financial aid funds by evaluation rounds
Source: own processing based on data from Minedu (2023a, 2023b, 2023c, 2023d, 2023e)

Figure 1 graphically shows the data on the requested and provided funds within the 8th evaluation rounds. The 7th round of evaluation is particularly significant, in which up to 99% of the required funds were provided as part of the financial aid. This result may indicate the high quality of the submitted applications, but also the emphasis on formal approval without a more rigorous substantive or in-depth check, which was typical of earlier rounds. In the 8th round, there was a significant decrease in the volume of requests, which may be related to the previous round, where needed funds requested by schools were provided and therefore the interest in aid decreased rapidly.

It should be noted that Table 1 and Figure 1 do not include the advance payment for 2024 of almost EUR 16.8 million, which was provided separately to schools and educational facilities at the end of 2023 outside the above types of financial support (Minedu, 2024a and Minedu, 2024b).

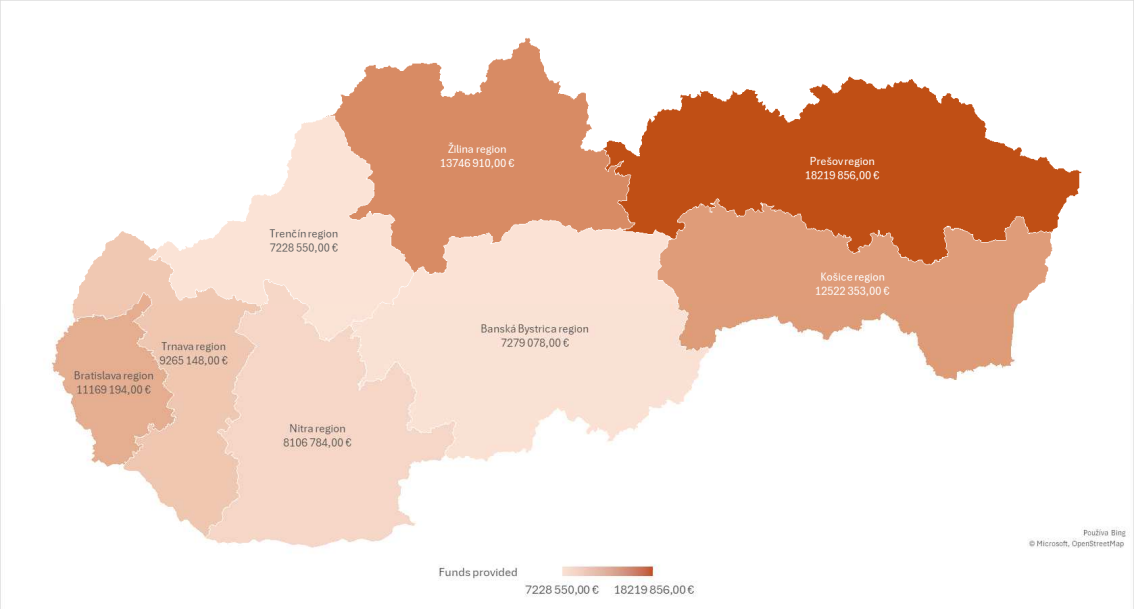

Figure 2. Funds provided to schools in regions in Slovak Republic in 2023 as part of aid to overcome the energy crisis
Source: own processing based on data from Minedu (2023a, 2023b, 2023c, 2023d, 2023e)

The data in Figure 2 show regional differences in the volume of provided funds, with the highest amount in 2023 being allocated in the Prešov Region (€18.2 million), followed by the Košice and Žilina Regions. On the contrary, the lowest volumes of aid were provided in the western part of the Slovak Republic.

Higher amounts allocated in more northern and climatically colder regions, such as the Prešov or Žilina regions, may be related to the higher energy demand of running schools during the winter months, as well as to the larger area and number of schools. These factors naturally increase the need for additional financing of costs associated with heating, energy and the operation of school facilities.

Despite the complexity of the situation and different conditions, it can be generally assessed that the Minedu approached the solution to the energy crisis in the school environment in a comprehensive and systemic manner, with an effort to cover the diverse needs of schools and school facilities across regions.

4. Discussion

The situation in Slovakia in 2023, when Minedu established the mechanism of financial aid to compensate for increased energy costs of schools, represents a practical example of a state intervention policy responding to the energy crisis. This system allows schools financed from the state budget and special school facilities to apply for additional financing of increased costs of electricity and natural gas above the capped price, with the financing supported by the Ministry of Economy of the Slovak Republic (80% of eligible costs) and the Ministry of Finance of the Slovak Republic (20% of eligible costs).

Similar state mechanisms are considered in the literature to be essential for ensuring the financial stability of educational institutions during energy crises, as rising energy prices can significantly threaten their operation and the quality of education provided (Paone and Bacher, 2018; Pinnington, 2025; Delardas and Giannos, 2022; Bertone et al., 2018). Efficient financing, which reflects the real amount of energy consumed and the year-on-year price increase, is in line with the recommendations of experts who emphasize the need for transparent and flexible financial instruments for public institutions (Anglum, Shores and Steinberg, 2021; Sweatman and Managan, 2010; Alam et al., 2019).

In the Slovak model, the “Conciliation Procedure” is also an important element, which ensures control and fair allocation of funds, thereby minimizing the risk of abuse and increasing the efficiency of the use of state resources. Control and transparency are often mentioned in the literature as key factors for successful public finance management, especially in the context of energy crises (Anessi-Pessina et al., 2020; Taylor et al., 2008; Hu, 2019; Jackson, Wigger and Xiong, 2021).

At the same time, it is clear that such short-term financial compensations should be complemented by longer-term investments in the energy efficiency of school buildings, such as modernization of heating systems, insulation, or the introduction of intelligent energy management systems (Chaer et al., 2025; Wang et al., 2022; Benkhalfallah, Kouah and Ammi, 2023), which bring benefits despite high initial costs (Stocker, Tschurtschenthaler and Schrott, 2015). Almasri et al. (2024) and Rosato, A., et al. (2019) also emphasize energy efficiency in the context of sustainable energy sources. These measures not only reduce the dependence of schools on unstable market energy prices, but also contribute to environmental sustainability and reduce operating costs in the long term (Hu; 2019; Xu et al., 2022).

However, a key aspect of the successful implementation of these measures is the need for interdepartmental cooperation. In addition to the Ministry of Education, coordination with the Ministry of Finance and the Ministry of Economy, which ensure financing and regulation of the energy market, is essential. Other departments, such as the Ministry of Environment, the Office for Spatial Planning and Development, and the Ministry of Informatization, Regional Development and Investments, play an important role in supporting the renovation and modernization of school buildings, ensuring environmental standards, and implementing digital solutions for efficient energy management. This comprehensive cooperation will allow schools to have sufficient financial resources not only to compensate for the increased costs, but also to renovate and transform their buildings into energy-efficient objects, thus preventing the liquidation consequences of the energy crisis without state intervention (Garcia and Torres, 2022; Anglum, Shores and Steinberg, 2021).

However, from an implementation perspective, it is also necessary to take into account the administrative burden associated with submitting applications and collecting data, which can be demanding for some schools (Bertone et al., 2018). Therefore, it is appropriate for state authorities to provide clear methodological instructions and support to schools in filling out forms and managing finances, which in the Slovak case is provided by the Minedu through a web platform.

Overall, the Slovak model of financing increased energy costs in schools is a prime example of a coordinated state approach to addressing the energy crisis in the education sector, reflecting the recommendations of international literature on the need for integrated financial and management strategies (Lee, Shores and Williams, 2022; Sulasmi, Prasetia and Rahman, 2023; Bellei and Contreras, 2024; Anglum, Shores and Steinberg, 2021). However, for sustainability, it will be essential to continue supporting energy efficiency while ensuring sufficient financing flexibility in the event of further price shocks.

Conclusion

The Slovak model of financing increased school energy costs in 2023 represents an effective example of state intervention that helped schools overcome the difficult period of the energy crisis. Coordinated cooperation between the Ministry of Education, the Ministry of Economy and the Ministry of Finance ensured a fair and transparent distribution of funds, thereby minimizing the risk of liquidation consequences for the school sector.

At the same time, experience and professional literature emphasize that short-term compensations are not enough. Systematic interdepartmental cooperation is necessary, which, in addition to financial support, also includes strategic investments in the energy efficiency of school buildings. The involvement of the departments of the environment, spatial planning, informatization, regional development and investment will enable a comprehensive approach to renovations and modernizations that will reduce the energy dependence of schools and contribute to their long-term sustainability.

Therefore, it is crucial that state authorities continue to develop integrated financial and management tools that will enable schools not only to cope with current challenges, but also to prepare for future energy shocks. Such an approach will ensure the stability and quality of education, while contributing to the environmental responsibility and economic efficiency of the school sector in Slovakia.

Abstract

Research background: The COVID-19 pandemic accelerated the adoption of remote work across various sectors, raising questions about its impact on employee motivation, productivity, and work-life balance. In the Nový Jičín district, a predominantly industrial region in the Czech Republic, technical and economic workers represent a specific group whose experiences with home office arrangements remain underexplored.
Purpose of the article: This article analyzes the impact of working from home on the motivation of technical and economic workers in Nový Jičín, identifying key barriers, motivational factors, and consequences for work-life balance. The study aims to inform human resource management practices and optimize remote work conditions in industrial regions.
Methods: A mixed-methods approach was employed, combining quantitative data from a structured questionnaire (n = 151) with qualitative insights from semi-structured interviews (n = 4). The questionnaire included closed, open, and scaled questions on remote work experiences, motivation, and working conditions. Data analysis was conducted using MS Excel.
Findings & Value added: The main barriers to remote work were technical issues, disrupted communication, and poor home office equipment. Motivation was higher in the office, driven by direct communication and efficient problem-solving. While remote work offered time and cost savings and flexible scheduling, it also brought difficulties in maintaining discipline and separating work from personal life, especially for women. Most respondents reported no major changes in physical or mental health, though some noted improvements from less commuting. These findings offer insights for HR professionals aiming to balance productivity, motivation, and well-being in remote work, especially in industrial regions.

Keywords: Remote work, Employee motivation, Work-life balance, Technical and economic workers, Industrial region

JEL classification: J24, M54, J81, O15

1. Introduction

Theoretical literature on remote work highlights a number of advantages, chief among them being flexibility in organizing working hours, savings in time and commuting costs, the possibility of better reconciliation of work and family responsibilities, and reduced stress from the work environment (Allen et al., 2015; Eurofound, 2020). On the other hand, a range of disadvantages is frequently cited, such as social isolation, disruption of team collaboration, difficulty in separating work from private life, the risk of declining work discipline, and increased demands on self-management (Felstead & Henseke, 2017; Oakman et al., 2020). These aspects are particularly significant in industrially oriented regions, where there is traditionally an emphasis on workplace presence and teamwork.

Employee motivation is a key factor influencing work performance, satisfaction, and long-term loyalty to the organization (Herzberg, 1968; Deci & Ryan, 2000). According to Herzberg's two-factor

* Corresponding author: petra.horvathova@vsb.cz

theory of motivation, both motivational factors (e.g., recognition, interesting work, responsibility) and hygiene factors (working conditions, workplace relationships, salary) play an important role. Remote work can affect both types of factors-for instance, by reducing opportunities for direct feedback and social interaction, but also by increasing autonomy and flexibility (Gajendran & Harrison, 2007). Research shows that motivation during remote work is often lower than in the office, which is related to limited communication, more difficult collaboration, and a lower degree of supervision by managers (Vega et al., 2015; Wang et al., 2021).

Work-life balance is currently considered one of the most important aspects of working life (Greenhaus & Allen, 2011). Remote work can improve this balance thanks to greater flexibility, but it can also lead to blurred boundaries between work and private responsibilities, which may cause stress and negatively affect psychological well-being (Allen et al., 2021; Eurofound, 2020). Studies show that women more often face difficulties in separating work and family, especially in households with children (Craig & Churchill, 2021).

The Nový Jičín district is the second smallest district in the Moravian-Silesian Region in terms of population. As of January 1, 2024, it had 151,781 inhabitants, of whom 75,052 were men and 76,729 were women. The average age of men is 41.4 years and of women 44.3 years, making the district one of the youngest in the region (ČSÚ, 2024a). Of the total 122,249 inhabitants over the age of 15, only 19,070 people have a university or higher professional education, with the largest part of the population consisting of people with secondary vocational education without a school-leaving certificate (Regionální informační servis, 2021). The district is known as an industrial-agricultural area with a predominance of mechanical engineering and electrical engineering, focused mainly on automotive manufacturing; the production of rubber and plastic products is also significant (Úřad práce ČR, 2025). The industrial orientation of the region may limit the prevalence of technical and economic employees working from home and influence their experiences with this mode of work.

The aim of this article is to analyze the impact of remote work on the motivation of technical and economic employees in the Nový Jičín district and to identify the main barriers, motivational factors, and effects on work-life balance. The research is based on a combination of quantitative and qualitative methods and brings new insights that may contribute to more effective human resource management and the optimization of conditions for remote work in industrially oriented regions.

2. Methods

The methodological approach of this study is based on a combination of quantitative and qualitative research methods, which enables a comprehensive perspective on the issue under investigation. The main quantitative method employed was a questionnaire survey, aimed at obtaining representative data on the experiences of technical and economic employees with remote work in the Nový Jičín district-specifically, those who currently work remotely or have previous experience with this form of work. Three research questions were formulated:

RQ1: Are technical problems, disruptions in work communication, or inadequate work equipment the most common barriers to remote work in the Nový Jičín district? This question aims to determine whether the main obstacles to remote work are of a technical, communicative, or ergonomic nature.

RQ2: Do changes in work discipline and a decline in productivity constitute differences in work motivation between remote work and office work? This question examines whether and how employees' work motivation changes depending on the work environment, and whether remote work leads to changes in work discipline or productivity.

RQ3: Are disruptions to work-life balance and increased stress among the negative impacts of remote work? This question focuses on whether remote work negatively affects the balance between work and personal life and leads to increased stress among employees.

The questionnaire consisted of closed, open-ended, and scale-based questions, and also included filtering and screening questions to ensure the relevance of responses. Respondents were selected through a combination of purposive and random sampling, with recruitment conducted via social networks, online groups, direct contact with companies, the VŠB-TUO career center, and the snowball method. Due to the distribution method, it is not possible to determine the exact total number of respondents approached. Out of 254 individuals who completed the questionnaire, 151 responses were evaluated as relevant based on established criteria. The data were analyzed using MS Excel, including the use of pivot tables and graphical processing of results.

The qualitative part of the research was conducted through semi-structured interviews with four selected respondents with varying demographic characteristics. The interviews were designed to supplement and deepen the insights gained from the questionnaires and to enable a more detailed understanding of individual experiences, motivation, and perceptions of work-life balance when working from home. The interview results were thematically analyzed and integrated into the overall conclusions of the article.

The entire research process was supported by systematic data collection and analysis, with an emphasis on the validity and reliability of the information obtained. This mixed-methods approach made it possible not only to quantify the main trends but also to capture the subjective aspects and nuances associated with remote work among technical and economic employees in an industrial region.

3. Results

The research on the impact of remote work on the motivation of technical and economic employees in the Nový Jičín district has yielded several noteworthy findings. From the broad dataset, particular attention was paid to comparisons of work motivation between home and office environments, the identification of motivational factors for both settings, and the main barriers encountered. The presented data are closely linked to the research questions but also extend beyond them.

3.1 Comparison of work motivation when working from home and the office

The data presented in Figure 1. reveal surprising findings. Respondents report significantly higher work motivation when working from the office. In this case, the combined categories of high and very high motivation reach 67%. In contrast, these two categories account for only 46% when working from home. Based on these findings, employers could reasonably conclude that it is more effective to have employees physically present at the workplace rather than working remotely.

These results also provide an answer to the question concerning work discipline and productivity decline during remote work. If motivation to work from home is substantially lower, it is reasonable to assume that work discipline is also reduced, which in turn negatively affects productivity.

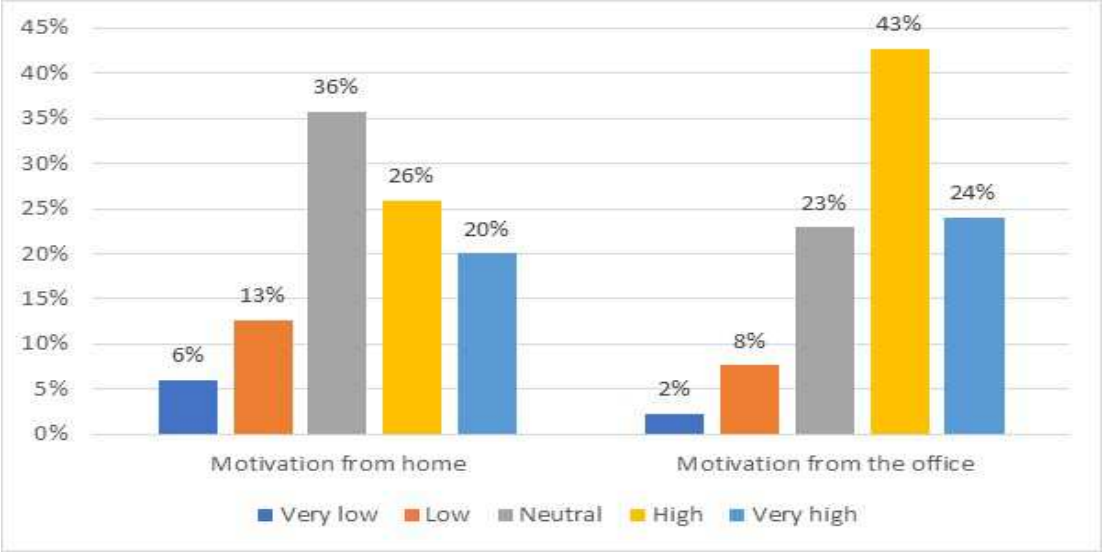

Figure 1. Work motivation from home and the office
Source: Nierostek et al. (2025)

3.2 Motivational factors for working from home

The data presented in Figure 2. to some extent, highlight the personal benefits employees perceive when working from home. The most valued advantage is the saving of time and commuting costs, with 31% of respondents of both genders identifying this as a key benefit. In second place, respondents appreciate the possibility of flexible work scheduling, a factor that is more important for women (28%) than for men (24%).

What lies behind this flexibility? On one hand, it reflects a positive optimization of the employee's work process when working remotely. On the other hand, it entails a degree of freedom that is often associated with lower discipline, which can consequently lead to reduced productivity.

An interesting gender difference emerges in the evaluation of the work environment. Men (23%) more frequently perceive a quiet and comfortable home workspace as a significant benefit compared to women (19%). Regarding stress reduction, both genders agree only at a level of 13%. This suggests that working from home reduces work-related stress only minimally.

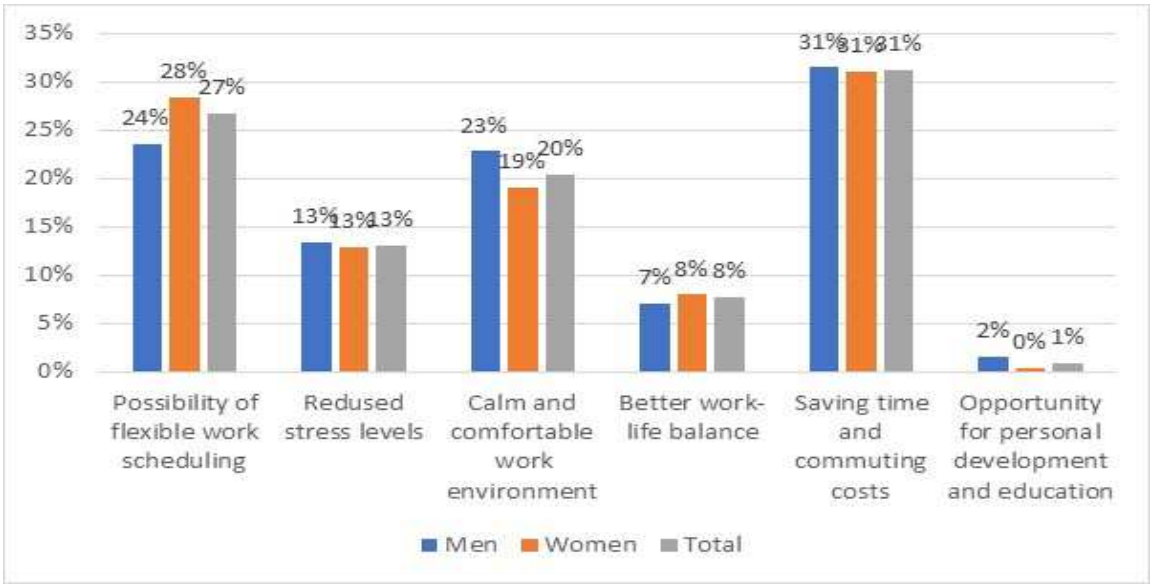

Figure 2. Beneficial factors of working from home
Source: Nierostek et al. (2025)

3.3 **Motivational factors of working from the office**

The most frequently cited positive factor of working from the office was direct communication with colleagues and supervisors (34%), indicating that social interaction with peers and the presence of management are highly important elements influencing employee motivation.

Another significant factor was the faster and more efficient resolution of problems (21%). This finding can be regarded as an established fact, not only supported by respondents in this particular study. It is evident that this factor enhances work efficiency, and consequently, productivity.

A clearer separation between work and personal life was identified by 17% of respondents as a motivational element of office work, whereas for remote work this figure is only 7% for men and 8% for women. Better work equipment and a more structured workday were noted by the remaining respondents-28%, 15%, and 13%, respectively.

3.4 Obstacles to working from home

The highest-rated obstacles to working from home, as illustrated in Figure 3., are difficulties in separating work and private life (19% of women, 17% of men) and distractions within the household environment (18% of women, 16% of men).

Slightly less problematic are maintaining work discipline (12% of women, 17% of men) and communication with colleagues (12% for both genders). Respondents perceive motivation as the least significant challenge, with 6% of women and 9% of men indicating issues in this area.

Technical equipment problems are reported by 13% of women and 10% of men, while difficulties in work-related communication are noted by 12% of both women and men. Insufficient workspace is generally considered a minor issue, affecting 6% of women and 5% of men.

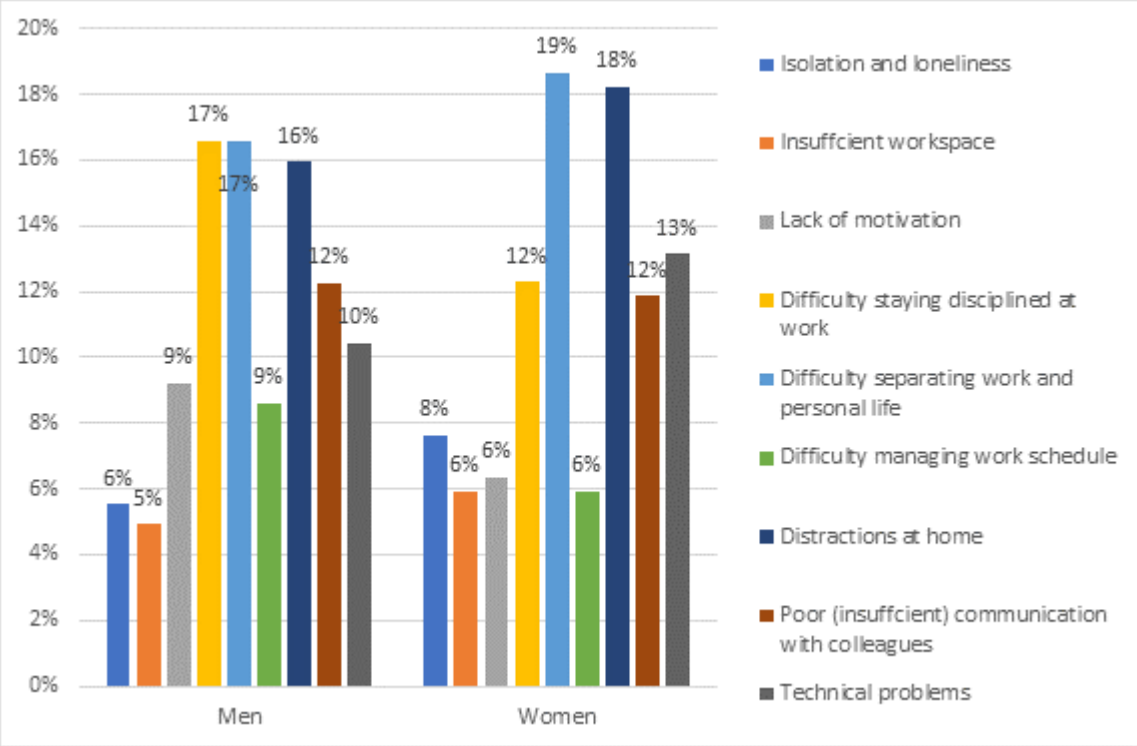

Figure 3. Obstacles to working from home
Source: Nierostek et al. (2025)

3.5 Additional Findings Related to the Research Questions

The data collection yielded a range of interesting findings (some illustrated in Figures 4., 5., and 6., while others are not graphically documented):

In response to the questionnaire item, "How often do you encounter technical problems when working from home?", 60% of respondents indicated that such issues occur only rarely. Only 8% reported experiencing technical difficulties frequently or very frequently.

Another question addressed whether work equipment constitutes one of the most common obstacles to working from home. In this regard, 14% of women and 22% of men rated this factor as rather negative or very negative.

Poor (insufficient) communication with colleagues was identified as the fourth most significant obstacle to working from home. In connection with a series of related questions, 45% of respondents indicated that they miss communication with colleagues.

The statement, "When working from home, my motivation to complete tasks within the planned timeframe often decreases," received strong agreement from 66% of respondents.

Moreover, 34% of respondents acknowledged the assertion, "I have difficulty maintaining work discipline when working from home."

Based on the conducted analysis, it can be concluded that 41% of respondents would prefer a hybrid work environment.

Only 21% of respondents strictly adhere to the working hours set by their employer.

Furthermore, 53% of respondents agree that they manage work-related stress better when working from home than in the office.

The majority of respondents (56%) reported no significant changes in either their physical or mental health while working from home.

However, 15% of participants indicated a deterioration in their mental well-being during remote work.

4. Discussion

The research on the impact of working from home on the motivation of technical and administrative employees in the Nový Jičín district has a twofold significance. Firstly, it primarily benefits employers within the district, as well as the broader Ostrava region, which is the most industrialized region in the Czech Republic. Working from home is offered by employers as a benefit, and the research findings confirm that it is indeed a benefi-not only in the sense of its voluntary nature but also, to some extent, in terms of reduced efficiency, motivation to complete tasks, work discipline, contribution, and productivity, all of which have implications for the employer.

When an employer allows remote work, they tend to have employees who are, in many respects, more satisfied, less fatigued, and better able to manage work-related stress. Perhaps even more importantly, these employees experience a sense of partnership and freedom-they know they can work from home. They are not obliged to, but they have the option and are aware of it. This is no longer an exceptional circumstance, as it was in the recent past. The survey revealed that the largest proportion of respondents (41%) prefer a hybrid work model.

The benefit of this research for the respondents themselves lies mainly in the fact that they were prompted to engage in deeper reflection on the topic and the content of working from home, including broader contexts. While completing the questionnaire, respondents could better recognize the advantages and obstacles of remote work. The same applies to the semi-structured interviews.

This article offers many interesting and inspiring findings. It indicates the need to continue seeking more detailed answers as to why these phenomena occur, considering not only gender differences but also perspectives across different generations, among other factors.

One of the most significant and somewhat surprising findings is that employees report a much higher level of motivation when working in the office (67%) compared to working from home (46%).

The research posed three primary questions. Research Question V1 asked: Are technical problems, disruptions in work communication, or inadequate work equipment the most common obstacles to working from home in the Nový Jičín district? The answer regarding technical problems is found in Figure 3., where technical issues affect 10% of men and 13% of women. Figure 5., which focuses solely on the frequency of technical problems, shows that 74% of respondents encountered such problems rarely or not at all. The importance of disrupted work communication as an obstacle is evident from Figure 4., where 45% of respondents reported missing communication with colleagues. Inadequate work equipment, as shown in Figure 6., is perceived by 22% of men and 14% of women as a hindrance to working from home. The conclusion is that technical problems do not constitute the most frequent obstacle to remote work. Disruption of work communication is a crucial issue, and inadequate work equipment should be regarded as a significant obstacle, particularly relevant for certain professions.

Research Question V2 asked: Do differences in work motivation between working from home and working in the office include changes in work discipline and a decline in productivity? Partially, this question is addressed by data from Figure 1., which shows that motivation is significantly higher in the office (67%) than at home (46%). These data suggest a visible change in discipline and, to some extent, a decline in productivity. The statement "When working from home, my motivation to complete tasks within the planned timeframe often decreases," as shown in Figure 4., was agreed upon by 66% of respondents. This high proportion may indicate that most employees face motivational challenges when working remotely, which in turn reflects lower work discipline and subsequent productivity decline. Only 21% of respondents admitted to strictly adhering to working hours. Semi-structured interviews did not yield a clear consensus, with both positive and negative responses. One illustrative response came from a 30-year-old male who expressed dissatisfaction with both environments: in the office, he is often disturbed by colleagues, while at home he is contacted due to insufficient information or newly arising problems. Overall, the data suggest that significant differences between working from home and working in the office include changes in work discipline and productivity decline.

Research Question V3 asked: Are disruptions in work-life balance and increased stress among the negative impacts of working from home? Regarding work-life balance and its negative effects, Figure 3. clearly shows that difficulties separating work and private time rank among the highest impacts for both men (17%) and women (19%). Related to this, and to the question of increased stress while working from home, Figure 3. also shows challenges in planning work time (men 9%, women 6%) and distractions within the household (men 16%, women 18%), which significantly influence stress levels.

Most research questions were addressed through multiple questionnaire items, providing comprehensive insights.

Conclusion

The aim of this article is to analyze the impact of working from home on the motivation of technical and administrative employees in the Nový Jičín district and to identify the main barriers, motivational factors, and effects on work-life balance.

The article is based on a combination of quantitative and qualitative research methods, which allowed for a comprehensive perspective on the investigated issue. The primary quantitative method was a questionnaire survey designed to obtain representative data on the experiences of technical and administrative workers with remote work in the Nový Jičín district. Research of this nature is among the first of its kind in the Czech Republic.

The questionnaire consisted of closed, open-ended, and scaled questions and also included filtering and screening questions to ensure the relevance of responses. Respondents were selected through a combination of purposive and random sampling, with outreach conducted via social media, online groups, direct contact with companies, the career center of VŠB-TUO, and a snowball sampling method. Due to the distribution method used, the exact total number of contacted respondents cannot be precisely determined. Out of 254 individuals who completed the questionnaire, 151 responses were deemed relevant based on established criteria. The data were analyzed using MS Excel, including the use of pivot tables and graphical presentation of results.

The qualitative part of the research was conducted through semi-structured interviews with four selected respondents representing diverse demographic characteristics. These interviews were designed to complement and deepen the insights obtained from the questionnaires and to allow for a more detailed understanding of individual experiences, motivation, and perceptions of work-life balance when working from home. The interview results were thematically analyzed and integrated into the overall conclusions of the article.

The entire research process was supported by systematic data collection and analysis, with an emphasis on the validity and reliability of the information obtained. This mixed-methods approach enabled not only the quantification of major trends but also the capture of subjective aspects and nuances associated with working from home among technical and administrative employees in an industrial region.

The authors successfully answered all the established research questions.

A limitation of the article is its focus solely on the Nový Jičín district and the relatively small number of respondents. This was a rapid and timely data collection intended to reflect the current situation in a smaller area, which naturally involved a smaller sample size. For greater data validity, it is necessary to continue increasing the number of respondents and to expand the data collection perimeter. This research is suitable for bachelor's, master's, and doctoral theses.

Further research opportunities include focusing on specific work sectors, professions, and related employee performance.

Deciphering Small Business Performance through Entrepreneurial Resilience: Empirical Findings from Sub-Saharan Africa

Timilehin Olasoji **Olubiyi**[1,*]

[1] Department of Business Administration, Faculty of Management and Social Sciences,West Midlands Open University Lagos State, Nigeria

Abstract

Research background: Small and medium-sized firms (SMEs) are seen as crucial to economic growth; despite their limited scale, they have substantially contributed to the advancement of major global economies. Due to their significant contributions, SMEs are considered the cornerstone of the Nigerian economy and indeed in Africa. Notwithstanding several initiatives and ongoing efforts by the Nigerian government in the business sector to assist SMEs in Nigeria, are yet to materialized, figures indicate that 70% of SMEs fail during their initial five years of operations, and large number of these enterprise lack entrepreneurial resilience.

Purpose of the article: Do small-business owners' entrepreneurial resilience enable them to swiftly recover from challenges and achieve performance? Is their entrepreneurial resilience heightened when they find the business environment as hostile? The objective of this work is to address this question. Therefore this study aimed to assess the impact of entrepreneurial resilience attributes on the business performance of selected small and medium-sized enterprises in Lagos State, Nigeria. An important market in Africa due to its large economy and population. This study contributes to addressing this research gap of entrepreneurial resilience in small businesses in sub-Saharan Africa.

Methods: The population consists of Small and Medium Scale Enterprises (SMEs) registered with the Small and Medium Enterprises Development Agency of Nigeria (SMEDAN) and operating in Lagos State. The target population was 4,535 small businesses in Lagos State. A sample size formula was used to select a sample size of 389 owner-managers. 389 copies of the questionnaire were properly filled out and returned through computer-assisted means (Google form).

Findings & Value added: The statistics indicate that entrepreneurial resilience traits substantially enhance performance. Risk-taking, innovativeness, and proactivity each yield significant advantages in profitability, competitive edge, and customer happiness, respectively. The research indicates that entrepreneurs must internalise and develop these resilience traits to enhance the success of their enterprises.

Keywords: Business performance, Entrepreneurial characteristics, Innovativeness, Pro-activeness, Risk-taking, SMEs

JEL Classification: JEL M10, M31, L25, O44

1. Introduction

As major corporations increasingly prioritise core competencies and implement extensive layoffs, the economic significance of Small and Medium Enterprises (SMEs) and entrepreneurship has markedly increased in recent decades (Van, 2005). Olubiyi (2024a) asserts that small and medium-sized enterprises (SMEs) have emerged as significant catalysts for economic growth and development in the rapidly evolving and competitive global economy. A strategy to sustain small and medium-sized firms (SMEs) is to enhance and fortify their entrepreneurial traits (Taneja, et al.,2025; Rahadhini & Lamidi, 2023). Entrepreneurial resilience (ER) is essential for business performance, especially during unpredictable periods (Shepherd et al., 2020). ER signifies a business's ability to surmount obstacles and adapt to

[*] Corresponding author: timi.olubiyi@westmidlands.university

unforeseen circumstances while upholding fundamental beliefs and modifying tactics to align with evolving market conditions, crucial for sustained success (Hillmann & Guenther, 2021). While the notion of ER has garnered interest in scholarly discourse (Salvato et al., 2020; Khurana et al., 2022), there is a need for more emphasis on small business performance and competencies with ER (Isensee et al., 2023; McElheran et al., 2024).

Numerous academics have recognised and demonstrated the vital significance of SMEs as a catalyst for development, job creation, competitiveness in global markets, and the general health and welfare of national and international economies (Elshaer, & Saad, 2022; Aremu & Lawal, 2012; Olubiyi 2024a; Olubiyi 2024b). Ogbuanu, Kabuoh, and Okwu (2014) assert that SMEs are fundamental to the Nigerian economy due to their significant contributions. The 2012 Enterprise Baseline Survey indicated that SMEs in Nigeria employed more than 32,414,884 individuals (SMEDAN, 2013). Approximately 58% of the global workforce can create job opportunities (Abor & Quartey, 2010). They also provide exceptional prospects for technological advancement, especially in companies with fundamental technology needs. Given the significance of entrepreneurial activity and SMEs to economic prosperity, it is essential to examine how small firms and entrepreneurs may enhance their performance and ensure their sustainability in an unstable economic environment. To navigate challenging situations, organisations may require certain talents, internal resources, or entrepreneurial characteristics such as creativity, adaptability, or flexibility (Ogbuanu, Kabuoh, & Okwu, 2014). The success of small and medium-sized enterprises is evaluated based on sales volume, profitability, return on capital, turnover rate, and market share acquired (Ahmad, Ramayah, Wilson, & Kummerow, 2010). Every small and medium-sized enterprise worldwide seeks sustainable competitive advantage and performance through entrepreneurial traits and behaviours that facilitate goal attainment (Taneja, et al.,2025; Fatoki, 2014). The Global Entrepreneurship Monitor Report (2015) indicates that the manner in which entrepreneurs demonstrate their attributes in everyday business interactions constitutes about 70% of a nation's economic prosperity and overall well-being. Ogundele, Olajide, and Ashamu (2008) assert that attributes of entrepreneurial resilience are essential for a nation's economic advancement. The impact of entrepreneurial resilience qualities has been examined by several researchers (Salamzadeh, Farjadian, Amirabadi, & Modarresi, 2014). As a result, the purpose of this study is to address the lack of knowledge by examining the impact of entrepreneurial resilience traits, such as risk-taking initiative, innovativeness, and proactiveness, on business performance, measured by profitability, competitive advantage, and customer growth.

2. Literature review

Entrepreneurial Resilience traits

Entrepreneurial resilience (ER) is essential for business performance, especially during unpredictable periods (Shepherd et al., 2020). ER signifies a business's ability to surmount obstacles and adapt to unforeseen circumstances while upholding fundamental beliefs and modifying tactics to align with evolving market conditions, crucial for sustained success (Hillmann & Guenther, 2021). While the notion of ER has garnered interest in scholarly discourse (Salvato et al., 2020; Khurana et al., 2022), there is a need for more emphasis on small business performance and competencies with ER (Isensee et al., 2023; McElheran et al., 2024). Numerous investigations have delineated the concept of entrepreneurial resilience capabilities in diverse ways. The several definitions provided cover a broad spectrum of dimensions and facets, from establishing a business to utilising entrepreneurial abilities and competences in virtually any context (Henry, Hills, & Leitch, 2013). Entrepreneurial resilience traits are generally regarded as a multidimensional construct at the organisational or entrepreneurial level, characterising the entrepreneurial behaviour of the entrepreneur or firm. This construct encompasses one or more of the following three dimensions: risk-taking, innovativeness, and proactivity (Njeru, 2013). An entrepreneurial feature is defined by the personal traits and abilities of the entrepreneur that contribute to their success (Abdulwahab & Al-Daman, 2015). Entrepreneurial resilience features emphasise the concrete, theoretical behaviours of individuals operating as solo entrepreneurs or within a team during the startup or initial phases of organisational development, often within the first six to seven years (Bird, 2012). It manifests as an independent entity comprising discrete activities that spectators may observe (Fisher, 2012).

Risk-Taking Initiative

Entrepreneurs must intentionally allocate resources to opportunities with varying probabilities of success or failure and be prepared to commit substantial resources to uncertain prospects (Baker &

Sinkula, 2009). Risk-taking necessitates a readiness to pursue opportunities that carry a significant likelihood of yielding losses or substantial performance variations (Morris, Kuratko, & Covin, 2008). Risk-taking is frequently associated with entrepreneurship, as the foundational definition of entrepreneurship encompasses the concept of personal risk-taking (Lumpkin & Dess, 2012). Risk-taking at the organisational level denotes the inclination to endorse initiatives with uncertain anticipated returns (Walter, Auer, & Ritter, 2006). According to Dess and Lumpkin (2010), organisations and their leaders face three categories of risks: business risk, financial risk, and personal risk. Longenecker (2006) categorises individuals as risk takers, risk minimisers, and uncertainty tolerators. They can also manage the stress of operating in such an environment, so enhancing their prospects for survival and success (Cunningham & Gorman, 2011). Rotter (2009) posits that individuals with a pronounced internal locus of control achieve their objectives through their own actions or unique resilience characteristics.

Innovativeness

Innovativeness is described as the ability to utilise natural resources to enhance productivity (Ogbuabu, Kabouh, & Okwu, 2014). It may also be described as the emergence or adoption of an innovative concept or practice within the organisation (Holland, 1997). Entrepreneurs leverage innovation to capitalise on change for the attainment of diverse companies or services (Mirela, 2008), and it is also a crucial element for a firm's survival, growth, and commercial success (Utterback, 2011). Innovation is an essential element of entrepreneurial mindset and a significant method for exploring opportunities (Lumpkin & Dess, 2012). Innovativeness has been recognised as the only constant theme in the literature on entrepreneurship. It is a fundamental element of any corporate strategy (Deakins & Freel, 2012).

Pro -activeness

Proactiveness is defined as the ability to take initiative, recognise and execute new business opportunities, and develop new markets (Auer & Ritter, 2006). Proactivity is characterised by the pursuit of possibilities or foresight (Lumpkin & Dess, 2012). Proactiveness is described as pioneering behaviour that entails taking the initiative to investigate opportunities (Lumpkin & Dess, 2008). Proactive individuals believe they can influence their environment (Li, Liang, & Crant, 2010). Individuals of this kind often assume the initiative to shape their environment instead of passively observing and reacting to surrounding occurrences (Bateman & Crant, 1993).

Business Performance

Assessing performance in enterprises is a significant challenge for scholars, policymakers, and real business proprietors/managers. Small enterprises frequently represent entrepreneurial ventures driven by the owner's objectives (Taneja, et al.,2025; Edmunds, 2012). Micro and small enterprises have significant challenges for survival, resulting in elevated failure rates. Business performance is defined as the efficiency of organisational management and the value delivered to consumers and other stakeholders (Wu, 2009). Owolabi and Makinde (2012) assert that an organization's commercial performance may be evaluated by minimising its environmental effect, enhancing employee health and safety, and augmenting consumer satisfaction. Adeoye and Elegunde (2012) defined business performance as the evaluation of how managers utilise organisational resources effectively and efficiently to attain objectives and fulfil stakeholder expectations. Business performance is characterised by the comparison of actual production to anticipated output and is classified into three categories: financial business performance, product market business performance, and shareholder return (Adeoye & Elegunde, 2012).

Profitability

The terms 'profit' and 'profitability' are occasionally utilised synonymously. Nonetheless, a contrast exists between the two concepts. Profit is an absolute notion, but profitability is a relative one (Olubiyi, 2024c; Tulsian, 2014). Profitability is an essential metric for assessing efficiency; yet, it cannot only be relied upon to ascertain efficiency. Profitability denotes an organization's ability to generate profit from its commercial activities. It illustrates how management may successfully leverage all available market resources for gain. Profitability, as defined by Harward and Upton (2014), is "the capacity of a specific investment to generate a return from its utilisation."

Competitive Advantage

Competitive advantage is characterised as a situation where issues arise in the reaJlm of competitive tactics, leading to several disagreements on its definition. Consequently, providing a concise description of competitive advantage is difficult (Rumelt, 2013). Competitive advantage refers to a corporation's ability to surpass its competition and achieve performance significantly above expectations (Peteraf, 2010). In the domainJ of competitive strategy and value creation, the predominant definition of competitive advantage is any factor that leads to revenue growth exceeding expenses (Rumelt, 2013). Besanko (2010) asserts that a firm possesses a competitive advantage if it generates an economic profit exceeding the market average. Hakkak and Ghodsi (2015) assert that competitive advantage fundamentally signifies a business's ability to produce goods or services that customers see as more valuable than those provided by competitors. Competitive advantage is now predicated not on tangible assets and capital, but on the efficient utiJlisation of intellectual capital and the customer's capacity to distinguish a company's product from its competitors (Antoncic & Hisrich, 2004; Reguia, 2014). Conversely, Esen & Uyar (2012) characterised competitive advantage as a strategy for establishing barriers that hinder competitors from replicating the organization's sources of strength.

Customer growth

Customer satisfaction is perceived as the response resulting from an evaluative process, since consumers must assess the gratification derived from a product or service (Al-Msallam, 2015). This is seen as an essential element of the organization's strategy, focussing on how a product or service fulfils or surpasses consumer expectations (Majida, Mohamadb, Zawawi, & Jamaluddin, 2017). Irfan (2014) posits that satisfaction is a reaction from a consumer who has attained fulfilment. Notwithstanding extensive research on customer happiness, a consensus on definitions remains elusive. 2010 (Cardozo). Halstead, Hartman, and Schmidt (2010) characterised customer growth as a transaction-specific emotional response resulting from the consumer's evaluation of product performance against a pre-purchase standard. Customer growth, as articulated by Mano and Oliver (2013), is an evaluative judgement resembling an attitude that fluctuates along the hedonic continuum post-consumption.

Entrepreneurial Resilience Traits and Business Performance

Researchers have determined that attributes of entrepreneurial resilience contribute to performance (Engelen, Gupta, Strenger & Brettel, 2015; Sarwoko, Surachman, Armanu, & Hadiwidjojo, 2013; Real, Roldan & Leal, 2014; Wijetunge & Pushpakumari, 2010). The examination of entrepreneurial resilience characteristics has garnered attention due to the significance of SMEs in economic advancement, particularly in developing countries. Syed, Muzaffar, and Minaa (2017) documented that attributes of entrepreneurial resilience enhance performance. This discovery is consistent with the results of Makinde and Asikhia (2017) and Quince and Whittaker (2003). Fairoz, Hirobumi, and Tanaka (2010), as well as Matsuno, Zhu, and Rice (2014), indicated a detrimental effect of entrepreneurial resilience attributes on performance. It was determined that attaining performance via entrepreneurial resilience attributes is contingent upon additional variables (Fatoki, 2012). Engaging in risk-taking initiatives results in enhanced performance (Jalali, Jafaar, Talebi & Halim, 2014; Naldi, 2011). Entrepreneurs who embrace risk consistently grow their businesses, and their propensity for risk-taking contributes to both financial and non-financial success (Osman, Ahmad, Rashid & Hussain, 2011). Lim (2010) and Wijetunge & Pushpakumari (2013) identified a favourable although negligible correlation between risk-taking initiatives and performance. Hughes and Morgan (2011) and Kreiser, Marino, Kuratko, and Weaver (2013) identified an inverse correlation between risk-taking and performance. Research indicates a significant correlation between innovativeness and performance (Arisi-Nwugballa, Elom & Enyeizugbe, 2016; Baldwin & Johnson, 2016; Kumarpeli & Semansinghe, 2015; Masona, Floreania, Miania, Baltramea & Cappellettoa, 2015; Ndalira, Ngugi & Chepkulei, 2013; Salavou, 2012).

Theoretical Review

The Discovery Theory

The theory referred to as the individual/opportunity nexus approach, focusses on the identification, discovery, and utilisation of possibilities, together with the influence of entrepreneurs on these

opportunities (Kirzner, 1973; Shane & Venkataraman, 2000; Shane, 2003). The Individual/Opportunity Nexus posits that opportunities are objective, individuals are unique, and entrepreneurs are risk-takers. The individual opportunity nexus elucidates entrepreneurship by analysing the connection between distinct individuals and objective possibilities. This perspective asserts that every price, invention, and piece of information have objective opportunities. Individuals identify and disseminate opportunities, but they do not generate them. This method involves entrepreneurs reconfiguring resources using a novel means-ends framework. Although the success of the opportunity at the time of discovery remains uncertain, the nature of the employed discovery allows for probabilistic anticipation of the outcome. Consequently, from this viewpoint, the entrepreneurial process pertains to risk rather than uncertainty.

Conceptual Model

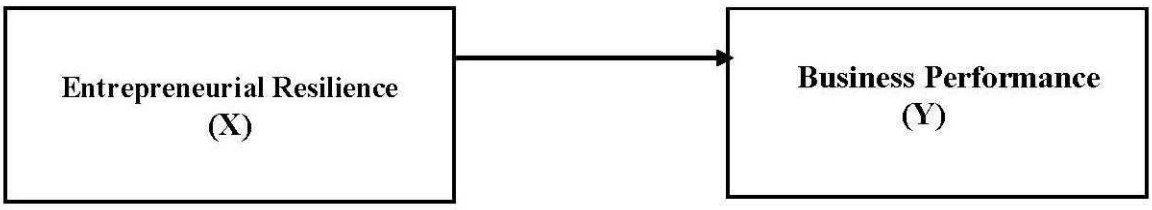

Figure 1. Author's Conceptual Model
Source: author (2025)

The model sheds light on the relationship between Entrepreneurial resilience traits and business performance, which is the research framework.

3. Methodology

This study employed a survey research design. This paper relied on the prior study methodology of Taneja, et al., 2025; Darda, et al., (2025); Olubiyi, (2024b),Adeyemi, and Olubiyi, (2023); Olowoporoku, and Olubiyi, T.O. **(**2023); Olubiyi, Lawal, and Adeoye, (2022). Olubiyi, Lawal, and Adeoye, (2022), Olubiyi, (2022a), and Olubiyi, (2022b). The study's population comprised 2,465 Small and Medium Scale Enterprises registered with SMEDAN and functioning in Lagos State, Nigeria. Small and Medium Enterprises Development Agency of Nigeria (SMEDAN, 2017). The SMEs utilised are those that have been in operation for more than five years. The study's sample size was 395, as estimated using the Krejcie and Morgan sample size table (1970). The study employed a mixed sample strategy, incorporating stratified, proportional, and basic random sampling techniques. The state was partitioned into four divisions: Yewas, Egba, Ijebu, and Remo (Bogunjoko, Hassan, Ogunro, Akanbi & Abudu, 2019).

4. Results and discussion

Data Analysis

389 copies of the questionnaire were properly filled and returned through computer-assisted means (Google form). This represented an overall positive response rate of 98% as presented in Table 1 from a distribution of 395 copies of questionnaire. Bryman and Bell (2011) posit that a response rate of ≥50% is appropriate to analyze the study's findings. A response rate of 98% was deemed to be very good for this study, thus, the researcher proceeded with the data analysis. The detail of the responses is shown in Table 1.

Table 1. Response Rate

Response Rate	Frequency	Percent (%)
Returned and used	389	98
Unreturned	6	2
Total	395	100

Source: Researchers' computation (2025)

Testing Study Hypothesis

To test hypotheses, a linear regression analysis was used to analyze the relationship between the entrepreneurs' resilience traits and business performance among selected small and medium-scale enterprises in Lagos State, Nigeria.

H_{01}: Risk-taking initiative does not significantly affect the profitability of the selected small and medium scale enterprises in Lagos State, Nigeria.

Table 2. Regression Results for Risk-Taking Initiative and Profitability

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.617[a]	0.381	0.379	3.20599
a. Predictors: (Constant), RISKT				

ANOVA[a]						
Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	2210.037	1	2210.037	215.018	0.000[b]
	Residual	3597.438	350	10.278		
	Total	5807.474	351			
a. Dependent Variable: PROFIT						
b. Predictors: (Constant), RISKT						

Coefficients[a]						
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	6.124	0.487		12.587	0.000
	RISKT	0.559	0.038	0.617	14.663	0.000
a. Dependent Variable: PROFIT						

Source: Field Survey (2025)

Table 2 indicates that risk-taking significantly enhances profitability, with P = 0.000 (R = 0.617 and P < 0.05). This indicates that risk-taking directly enhances profitability in the SME sector. The model R2 (coefficient of determination is 0.381) indicates that the risk-taking initiative influences SMEs' performance, accounting for 38.1% of the variance in profitability. The F statistic is 215.018, significant at P<0.05, demonstrating that the hypothesis 1 model significantly determines the impact of risk-taking initiatives on profitability. A positive and substantial standardised B coefficient ($\beta = 0.559$, t = 12.587, P<0.05) substantiates this claim. The null hypothesis, asserting that risk-taking does not significantly affect the profitability of the chosen small and medium-sized enterprises in Lagos State, Nigeria, is rejected. Arisi-Nwugballa, Elom, and Enyeizugbe (2016); Baldwin and Johnson (2016); Kumarpeli and Semansinghe (2015); Masona, Floreania, Miania, Baltramea, and Cappellettoa (2015); Ndalira, Ngugi, and Chepkulei (2013); Salavou (2012). Wijetunge and Pushpakumari (2013) also support it. Nonetheless, it contradicts the findings of Hughes and Morgan (2011) as well as those of Kreiser, Marino, Kuratko, and Weaver (2013). The variance in these results may be ascribed to the characteristics of the business environment and other inherent resilience attributes that vary between research contexts. Profitability is contingent upon the owner/manager's propensity to assume risks. Consequently, the flexibility to undertake a new, potentially hazardous project may enhance profitability.

H_{02}: There is no significant effect of innovativeness on the competitive advantage of the selected small and medium-scale enterprises in Lagos State, Nigeria.

Table 3. Regression Results for Innovativeness on Competitive Advantage

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.649[a]	0.421	0.419	3.06968

a. Dependent Variable: COMPAD						

Source: Field Survey (2025)

Interpretation

Table 3 indicates that innovativeness exerts a significant positive effect on competitive advantage, evidenced by a P-value of P = 0.000 (R = 0.649 and P < 0.05). This indicates that in the SME sector, innovativeness directly enhances competitive advantage. The R^2 model, with a coefficient of determination of 0.421, indicates that innovativeness influences SME development, accounting for 42.1% of the variation in competitive advantage. The F statistic is 254.457, significant at P < 0.05, demonstrating that the model for hypothesis 2 effectively identified the impact of innovativeness on competitive advantage. A substantial and noteworthy standardised B coefficient (β = 0.622, t = 10.538, P < 0.05) corroborates this finding. The null hypothesis is rejected, indicating that innovativeness significantly influences the competitive advantage of selected small and medium-sized enterprises in Lagos State, Nigeria. The findings of this study align with the research conducted by Arisi-Nwugballa, Elom, and Enyeizugbe (2016), Baldwin and Johnson (2016), Kumarpeli and Semansinghe (2015), Masona, Floreania, Miania, Baltramea, and Cappellettoa (2015), Ndalira, Ngugi, and Chepkulei (2013), and Salavou (2012). The discovery indicates that when a management or organisation exhibits innovativeness, the company acquires a competitive advantage, since innovativeness fosters competitive superiority.

H_{03}: Proactiveness has no significant influence on the customer growth of the selected small and medium-scale enterprises in Lagos State, Nigeria.

Table 4. Regression Results for Pro-Activeness on Customer growth

Model Summary				
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	0.739[a]	0.546	0.545	2.71679
a. Predictors: (Constant), PROACT				

ANOVA[a]						
Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	3112.413	1	3112.413	421.682	0.000[b]

	PROACT	-0.739	0.036	0.739	20.535	0.000
a. Dependent Variable: CUSTGWT						

Source: Field Survey (2025)

With a P-value of P = 0.000 (R = 0.739 and P < 0.05), Table 4 indicated that proactiveness exerted a highly significant positive impact on customer growth. This indicates that proactivity directly enhances customer growth in the SME sector. The R^2 model, with a coefficient of determination of 0.546, indicates that proactiveness influences SMEs' performance, accounting for 54.6% of the variance in customer growth. The F statistic is 421.682, significant at P < 0.05, suggesting that the model for hypothesis 3 effectively identified the impact of proactivity on customer growth. A substantial and noteworthy standardised B coefficient (β = 0.739, t = 7.798, P < 0.05) corroborates this finding. The null hypothesis, asserting that proactiveness does not significantly affect customer growth in the chosen small and medium-sized enterprises in Lagos State, Nigeria, is rejected. The conclusion aligns with the study findings of Sturm, Hohenstein, and Hartmann, (2023), Hughes and Morgan (2011), Kusumawardhani (2013), and Muhammad (2014), which indicated that proactiveness significantly influences SME performance, especially with customer growth. The results align with those of Aremu and Lawal (2012), who identified a positive correlation between proactiveness and performance. This indicates that proactive decision-making by an entrepreneur enhances the enterprise's performance. Nigerian business experience indicates that organisations exhibiting robust entrepreneurial proactiveness positively correlate with performance metrics, continually expanding in size and hiring qualified, competent personnel. A proactive corporation may resolve client complaints, fostering customer loyalty and enhancing satisfaction.

Conclusions and recommendations

The study findings indicate that most respondents concurred that attributes of entrepreneurial resilience affect the performance of SMEs. The attributes of entrepreneurial resilience positively influence the success of SMEs, demonstrating a link at a 95% confidence level. The research examined the impact of entrepreneurial resilience qualities on the business performance of selected small and medium-sized enterprises in Lagos State, focusing on sub-variables such as risk-taking initiative, innovativeness, and proactiveness. The study concludes that risk-taking initiatives significantly impacted the profitability of selected small and medium-sized enterprises in Lagos State, Nigeria (β = 0.559, t = 12.587, P < 0.05). Additionally, innovativeness significantly affects the competitive advantage of these enterprises (β = 0.622, t = 10.538, P < 0.05), and proactiveness significantly influences customer growth among the selected small and medium-sized enterprises. Consequently, it is advisable for entrepreneurs to undertake calculated risks to enhance their company's success. In this technologically advanced day, innovation must not be overlooked to remain aligned with reality and provide the necessary product or service to consumers promptly. Ultimately, they must adopt a proactive approach to satisfy client requests. Entrepreneurs must to be motivated to anticipate and actualise novel opportunities, as well as to establish new markets among business environmental challenges, to satisfy existing consumers and entice prospective customers.

Sports Management in the Dimensions of Managerial Functions

***Iveta* Petríková Rosinová**[1,*] **and *Jana* Korcová**[1]

[1] University of St. Cyril and Methodius in Trnava, Faculty of Health Sciences, Rázusova 14, 921 01 Piešťany, Slovakia

Abstract

Research background: Sports management emerged as a response to the needs of sports practice and is constantly evolving in line with the demands of modern society. It is a multidisciplinary field that includes elements of management, marketing, communication, economics and sports expertise.
Purpose of the article: The aim of the paper is to highlight the importance and basic structure of sports management, focusing on key management functions such as planning, organizing, leading, motivating and controlling. The paper outlines the requirements for a sports manager – his/her competencies, roles and abilities necessary for effective management of sports teams and organizations. At the same time, it analyses team management and change management in the context of current trends in sports.
Methods: The paper uses a combined research design. In the quantitative part, a questionnaire survey was conducted to determine the level of public interest in sports in the Trenčín region. The qualitative part of the research was conducted in the form of semi-structured interviews with representatives of the Secondary Sports School and the Hockey Academy in Trenčín with the aim of mapping the level of management in sports teams and clubs.
Findings & Value added: The research results show that sports management plays a significant role in supporting and effectively functioning sports organizations. Quantitative analysis showed different levels of public engagement depending on the quality of sports infrastructure and the activity of local governments. Qualitative data revealed different approaches to team management - from an educational-sports model to a professional performance-oriented environment.

Keywords: Sport, Management, Dimensions, Functions, Leading

JEL classification: I20, J50, J58

1. Introduction

The managerial function is a relatively separate but integrated part of the work activity in management, each function has a specific role. By harmonizing the managerial functions with each other, the set goals can be achieved (Anglin et al. 2022). Kilíková and Jakušová (2008) state that in practice there are certain barriers that prevent the successful implementation of managerial functions. These are mainly:

- limited resources - lack of finances, need for quality human resources and others,
- technological limitations,
- attitudes and expectations of others, their willingness to adopt the manager's intentions or willingness to tolerate them,
- and others.

1.1 Management Functions

The application of basic management functions to the process is the basis for successful management of managers. The basic management functions are planning, organizing, leading people, and controlling.

[*] Corresponding author: iveta.petrikova@ucm.sk

- **Planning in management**

Jakušová (2017) emphasizes that planning is a basic managerial function that takes up a significant part of the working time of top managers. The key task of planning is the process of formulating goals and determining ways to achieve these goals at the desired level in a given time.

The output of planning is a plan that is effective when the set goals are achieved at appropriate costs. According to the time horizon, we divide plans into:

- operational plans – compiled for a week, month, quarter, etc.,
- budget plans – oriented to a period of one year,
- business plans – mainly prepared for one to two years,
- strategic plans – compiled for three to five years, even for a longer period.

- **Organizing as a management function**

Lednický (2000) writes that the organizing process can be expressed in the form of a chain of requirements known as OSCAR. It consists of:

- O – Objectives,
- S – Specialization,
- C – Coordination,
- A – Authority,
- R – Responsibility.

- **Leading people in modern management**

Leading people is an important managerial function, as the results of the entire team depend on the leadership style (Courtright et al. 2025). Krause and Miller (2020) state that leading people should be understood as a complex work with human resources. Managers acquire the ability to lead people through management education and also based on experience in practice. The classic leadership styles are based on the use of the manager's authority:

- autocratic: he decides himself what and how to do. Kilíková and Jakušová (2008) state that it is not essentially about leading people, but about their mechanical directing.
- rational-empirical: this style assumes management by the individual's own reason. The manager reviews various proposals and strives to apply them in practice.
- democratic: the manager makes decisions only after talking and discussing with others, takes into account the opinions of others.
- participative: it is essentially a compromise between the autocratic and democratic style, the manager requires others to express their opinion and criticize.
- Laissez-faire style: it is essentially a free-hand style, where the manager leaves events to their own devices. There is no order, discipline, or mutual respect.
- power-coercive: it is essentially a top-down method, the manager orders and issues instructions. This style prevents initiative and creativity.
- normative-re-educational: the manager strives to involve everyone in all processes (Jakušová 2017).

Spicer and Alvesson (2024) emphasize that the effectiveness of leadership depends on the situational conditions in which it is carried out. Which leadership style a manager should prefer depends on the characteristics and abilities of the manager, as well as the specific management conditions in a particular organization (Moriarty, 1984).

- **Control in management**

Sedlák (2012) states that controlling is closely related to planning, the essence of control lies in monitoring and evaluating the progress and status of implementation of plans. Without evaluating and controlling the achieved results, it is impossible to assess the effectiveness and success of other management functions, and therefore the work of the manager.

Varmus and Adámik (2023) write that management in sports includes managerial skills and activities in managing a sports organization in achieving goals that are specific to the sports environment.

Management in professional sports is an important element that affects the performance of teams and athletes, the financial sustainability of the organization and the overall success in sports. Sports management can include:

- developing players, coaches and staff,
- increasing revenue through ticket sales and sponsorships,
- improving the fan experience,
- an effective marketing and promotional strategy,
- a sustainable budget,
- implementing strategic plans,
- monitoring performance measures to evaluate success,
- improving community engagement and awareness,
- brand recognition and sports promotion
- risk management and safety,
- and others.

Sports management is a complex, dynamic field that is constantly evolving. Growing competition between sports organizations creates new challenges but also opportunities.

Sports marketing in the digital era plays a significant role, as various social media and mobile platforms have emerged, the internet has spread, and fans have instant access to sports-related content. This includes live broadcasts of matches, as well as exclusive behind-the-scenes footage. This is of great importance for sports marketing and brand building.

An important role in sports management is played by performance management and training processes, as well as the personnel management of athletes.

The specifics of sports management as follows:

- Irrational passions,
- Profit or win,
- Competitive balance,
- Variable quality,
- Anti-competitive behavior,
- Brand loyalty,
- Identification and imitation,
- Blind optimism,
- Technologies,
- Availability.

As for sports management, its development in our country, we cannot precisely define the division of development in Slovakia. We only follow changes in the relationship between state policy and sports towards its financing. We distinguish the following historical periods:

1. period of the Czechoslovak Socialist Republic (1948–1989),
2. period of the Czechoslovak Federative Republic (1990–1992),
3. period of the Slovak Republic (since 1993).

The basic division of sports management is presented by Cimboláková and Melichar (2023) as follows:

o **Management and commerce**

- functions of a managerial nature: planning, organizing, leading people, control,
- other areas such as marketing, accounting, economics, finance, law,
- sport through the eyes of a sports manager,
- spectators: this means entertainment consumption,
- active participation of participants in sports and physical education activities.

1.2 Team management, roles and levels of a manager

In modern management, we encounter various theories of motivation, whether they are:

- theories of need – they examine the knowledge of the causes of motivation,
- theories of the motivation process (Kilíková, Jakušová 2008).

Part of the internal environment of an organization is a team, which is made up of individuals with different characteristics, abilities, skills, etc. A very important aspect is the composition of the team and the relationships and dynamics taking place within it (Mahajan, 1992).

Every concept of teamwork must be built on certain features of teamwork. In the process of team formation, we distinguish the following developmental phases of the team.

Hekelová (2012) describes the main roles of a manager in change as follows:

- executor - changes come to the manager from the outside environment,
- mediator - changes come from the environment to the manager, who moves them forward,
- initiator - the manager himself implements the change, which is aimed at improving the process.

Veber (2003) states that communication forms a significant part of the manager's work activities. The basis of communication as a managerial function is simplicity, clarity, conciseness and initiative of all forms of expression.

We classify sports management as an interdisciplinary science, as it uses methodological procedures from various disciplines:

- economics,
- psychology,
- sociology,
- law,
- management,
- other system sciences.

The role of a manager consists of a complex of many complex tasks, functions, and responsibilities. We list the individual levels of a sports manager:

- Managers at the level of sports activities management (leaders of sports teams, individuals in higher competitions, experts in the preparation of sports events, etc.),
- Managers at the level of sports club management, organization (leaders of sports centers, union secretariat, members of executive sports and physical education unions),
- Managers in the business sector (manufacturing of sports products, fitness managers, marketing agency workers, and others) (Čáslavová 2020).

Management in sports represents the management of all processes associated with sports organizations, teams, events, or athletes.For example:

- planning – it is about setting performance, economic and strategy goals,
- organizing – it is related to creating team structures, managing coaches, athletes, employees,
- leadership – we mean motivating athletes, building team culture,
- control – it is about monitoring performance, finances, training results, competitions and others.

When managing, it is necessary to focus on whether it is about managing:

- the entire sports organization: National Sports Federation,
- a sports event: organizing a marathon,
- an athlete: personal manager of an athlete, skier and others,
- a professional team: football club, hockey club and others.

1.3 Characteristics of a manager in sports

A manager in sports must have many factors:

- communication skills – has knowledge of clear and effective communication (with athletes, media, fans, sponsors, etc.).
- organizational skills – has the ability to plan training, matches, events, manage time and priorities.
- leadership skills – can inspire and motivate athletes, coaches, the rest of the team, has responsibility for leadership and can set goals.
- professional skills – has knowledge of training and competition principles, understands sports processes, rules in sports.
- financial and marketing literacy – can build a club brand, get sponsors, work with a budget, plan income and expenses.

- emotional intelligence – can handle stress and pressure, especially in situations of ongoing matches, tournaments. Has empathy for athletes and colleagues.
- flexibility and adaptability – can deal with a quick response to changes such as player injuries, rule changes and unexpected situations.

The work of a sports manager requires a number of complex and gradual steps, approaches, solutions and is also tied to the specialization itself.

The field of sports is currently demanding on the quality of management functions, on the professionalism of the manager.

A successful manager, write Cimboláková and Melichar (2023), is a person who has excellent knowledge, experience and authority in his/her given area. A successful manager is:

- self-confident, intelligent, initiative-taking,
- has the ability to recognize the abilities of other people,
- knows how to rise above the situation and see it in a broader context (this is a helicopter trait).

2. Methods

In the empirical part, we used a mixed methods research design, which, as Ondrejkovič (2017) states, combines quantitative and qualitative approaches in order to obtain a more comprehensive view of the research issue. The combination of both approaches allowed us not only to capture broader trends in public attitudes, but also to gain a deeper understanding of the management of sports clubs at the institutional level.

The quantitative part of the research was carried out through a questionnaire survey. The aim was to determine the public's interest in sports in the Trenčín region. The questionnaire was anonymous and its aim was to map the attitudes and opinions of the residents of the Trenčín region on the level of sports infrastructure, support for sports activities by the local government, and their expectations in the area of sports development. High-quality infrastructure is the basis for the effective functioning of services, which is also needed by Bočáková and Potočný (2018).

In the qualitative part of the research, we used semi-structured interviews. We conducted these with participants from the Trenčín Secondary Sports School and the Trenčín Hockey Academy. The aim of this phase was to map the level of governance in a sports team/club and to understand the inner workings of these organizations. The interviews focused on areas such as organizational structure, leadership style, planning of the training process, cooperation with parents and the community, as well as the challenges that sports clubs face. The participants' statements allowed us to identify the strengths and weaknesses of the current governance and provided a deeper context for interpreting the quantitative findings.

3. Results

The following section provides an overview of the main results of quantitative and qualitative research, the aim of which was to map the state of sports infrastructure, the perception of support for sports by local governments, and the level of governance in sports organizations. The results provide a valuable insight into the current situation in the Trenčín region from the perspective of both the public and representatives of sports institutions.

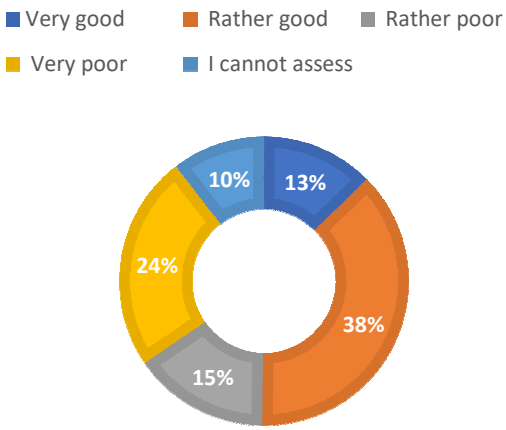

Figure 1. Evaluation of the offer of sports facilities and opportunities for the public in your city (e.g. playgrounds, sports halls, running tracks)
Source: own processing (2025)

Most respondents (39.6%) consider the offer of sports facilities in their city to be rather good, which indicates general satisfaction, but with room for improvement. 25.5% of respondents expressed great dissatisfaction (marked the assessment as very poor), which points to a significant share of residents who perceive a lack or poor quality of sports infrastructure. 15.9% marked the assessment as rather poor, which together with the previous category means that more than 41% of respondents perceive the offer of sports facilities negatively. Only 13.2% of respondents marked the offer as very good, which represents a low share of strongly positive assessments. 10.9% could not comment on the question, which may indicate either a lack of interest in the topic or insufficient information about the options in the city.

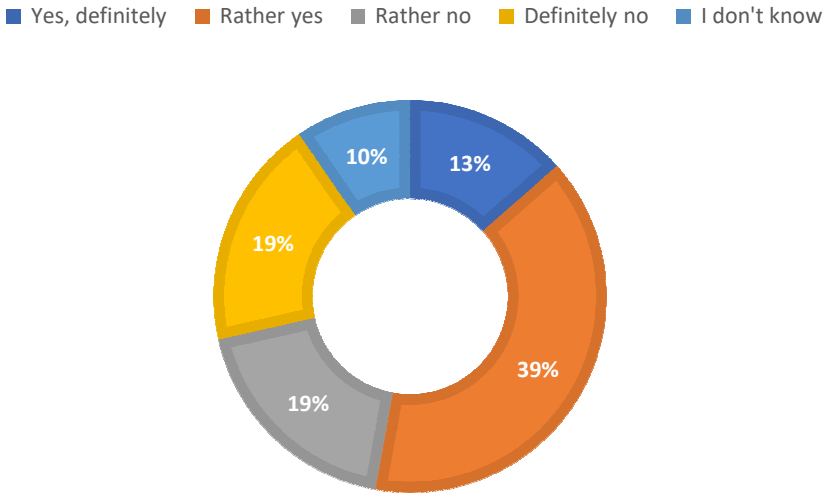

Figure 2. Support for the development of sports and physical activities of residents by the local government
Source: own processing (2025)

A positive assessment (sum of “Yes, definitely” and “Rather yes”) was expressed by 122 respondents (52.6%), which indicates that more than half of the public perceives some form of support for sports from the local government. A negative assessment (sum of “Rather no” and “Definitely no”) was expressed by 87 respondents (37.5%). This group represents a significant proportion of residents who are convinced of insufficient support for sports activities. 9.5% of respondents (22 people) could

not express an opinion on the question, which may indicate either low awareness of the local government's activities in this area or poor communication and promotion of these initiatives.

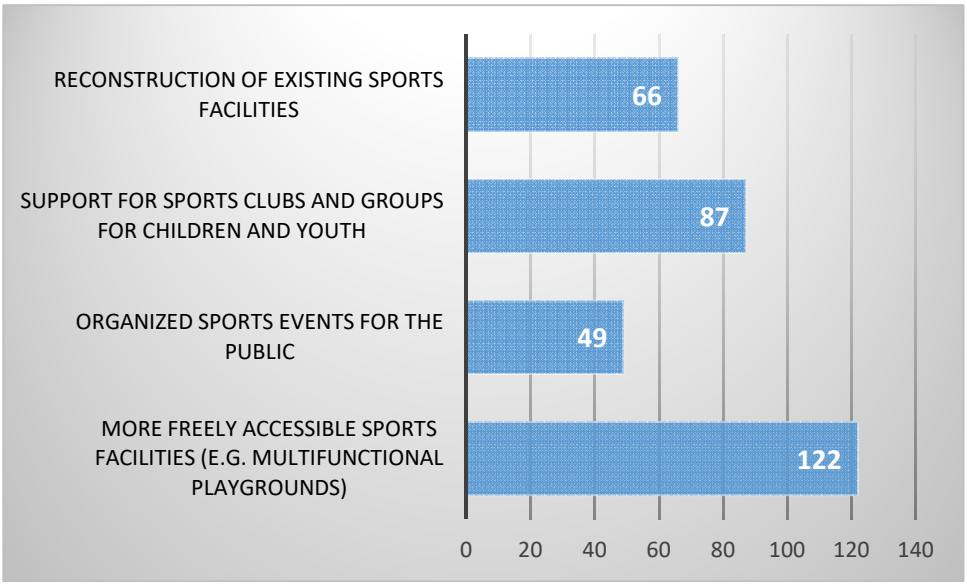

Figure 3. Missing forms of support for sports from the local government (multiple answers possible)
Source: own processing (2025)

The public expressed the greatest interest (122 responses) in increasing the number of freely accessible sports facilities, which indicates a strong need for accessible and non-commercial spaces for sports activities. 87 respondents would welcome greater support for clubs and groups for children and youth, which indicates the public's emphasis on systematic and long-term building of sports habits in the younger generation. Reconstruction of existing sports facilities was also a significant requirement (66 responses), which may be related to the perceived obsolescence or neglected state of the infrastructure. Organized sports events for the public received relatively fewer responses (49 responses), which may indicate that long-term accessible spaces are more important to the public than one-off events.

Table 1 provides an overview of the key differences between the management of a Secondary Sports School and a Hockey Academy. It compares their focus, structure, leadership style, values, and challenges that affect the functioning and development of both types of sports institutions.

Table 1. Comparison of management levels in qualitative research

Management area	Secondary sports school	Hockey academy
Focus	Educational-sports model	Performance-professional model
Management Structure	Links the school with the training process, cooperation with teachers	Clearly hierarchical, team of experts (coaches, analysts, psychologists)
Leadership Style	Support for discipline, planning and systematicity	Performance orientation, use of analyses and technologies
Communication	Regular assessments, school-coach-student cooperation	Intensive communication with players and parents, feedback
Values	Individual development, responsibility, school success	Performance, professionalization, mental resilience
Strengths	Linking education and sport, stable environment	Professional background, specialized support team
Challenges	Financial resources, infrastructure, coordination with the school	Long-term planning, acquisition of experts, financing
Level of Management	High, with emphasis on pedagogical context	High, with emphasis on performance and professional growth

Source: own processing (2025)

4. Discussion

Movement is a fundamental aspect of human life, as it significantly influences the physical, mental and social health of an individual. It is an integral part of a healthy lifestyle and overall human development. (Draková 2024). The results point to an uneven assessment of sports infrastructure, with a significant proportion of the public perceiving gaps in the availability or quality of sports facilities. These findings may be important in deciding on future investments in sports infrastructure within the cities of the Trenčín region.

As Vojtech et al. (2019) point out, successful cooperation and coordination between various entities are essential for achieving common goals and effective development.

The results point to a slightly prevailing positive perception of local government support for sports, but a large proportion of critical responses and hesitant respondents indicate that there is room for improvement – especially in the areas of transparency, communication and effectiveness of sports initiatives for residents.

Respondents most often pointed to the lack of accessible sports facilities as the most significant gap in local government support for sports. These results may be an important recommendation for local authorities when planning investments and developing sports infrastructure. Emphasis should be placed in particular on accessibility, sustainability and support for youth sports.

A qualitative analysis of management in sports organizations – in the case of a secondary sports school and a hockey academy in Trenčín – showed that both institutions face several challenges in the area of organizational and strategic management. The secondary sports school focuses on an educational-sports model with an emphasis on discipline, school success and cooperation between teachers and coaches. Management is oriented towards pedagogy and systematicity. On the contrary, the Hockey Academy operates on a performance-professional model, emphasizing performance, analysis, technology and a professional team of specialists. Communication is more intensive, with the aim of achieving a high sports level and mental resilience. Each area has its strengths and challenges, with the school dealing with finances and infrastructure, the academy focusing on experts and long-term planning.

As Vojtech et al. (2019) state, effective management and strategic planning are cited as crucial for the development and stability of regions.

Effective management also includes managing employees' psychosocial risks, which, according to Slovák et al. (2022), significantly contributes to better work well-being and team performance.

Conclusion

Currently, the field of sports is demanding on the quality of management functions and is related to the professionalism of the manager, because management is not only an art, but also a science.

The research findings point to the need for systematic support for sports at the level of local government and in the sports organizations themselves. On the one hand, there is an obvious public need for better accessibility and quality of sports infrastructure, on the other hand, an analysis of the internal functioning of sports institutions revealed weaknesses in management, planning and support of professional background.

Microcredentials and Their Potential for Lifelong Learning and Human Resource Management

***Simona* Polonyová**[1,*]

[1] Bratislava University of Economics and Business, Department of Social Development and Labour, Faculty of Economics and Finance, Dolnozemská cesta 1, 852 35 Bratislava, Slovakia

Abstract

Research background: Rapid technological advancement, automation, and changing labour market demands necessitate the continuous renewal and enhancement of individual skills. Traditional forms of education often lack the flexibility to respond effectively to these shifts. In this context, microcredentials emerge as an innovative tool that can facilitate access to relevant and customized lifelong learning opportunities.
Purpose of the article: The aim of this paper is to present the potential of microcredentials as a tool for fostering lifelong learning within a digital and flexible educational environment and to identify emerging trends in the use of microcredentials from the perspective of educational policy, practice, and human resource management.
Methods: From a methodological perspective, this paper is based on desk research and draws on a systematic analysis of scientific literature as well as documents and reports produced by European and international organizations. The research focuses on two closely interconnected areas: (1) mapping the current state of the perception of microcredentials in the context of lifelong learning, and (2) identifying emerging trends related to microcredentials.
Findings & Value added: The paper offers a contemporary perspective on emerging trends in the field of microcredentials and their linkage with the concept of lifelong learning. It contributes to the discussion on the possibilities of effectively integrating microcredentials not only as a complementary tool in adult education, but also as a strategic instrument in human resource management, enabling organizations to flexibly respond to skill shortages, and strengthen economic adaptability in a changing environment.

JEL classification: I00, I25, I28, I29

1. Introduction

The contemporary world of work is undergoing dynamic changes driven by globalization, technological advancement, automation, and digitalization. These changes fundamentally impact the structure of employment, the nature of jobs, and the skills required of workers. One of the main challenges employers face is the insufficient supply of relevant skills in the labour market. The World Economic Forum's Future of Jobs Report 2023 forecasts that 61% of workers will require retraining between now and 2027 (World Economic Forum, 2023).

Continuous upskilling and reskilling are essential for workers to respond to the demands of their current jobs or to transition to new employment opportunities. Traditional forms of education may not respond quickly enough to these changes. This creates a need for more flexible and accessible forms of learning. In this context, the importance of lifelong learning is increasingly emphasized. The concept of lifelong learning is based on the premise that learning does not end with initial formal education but continues throughout an individual's life in various forms - formal, non-formal, and informal (Council of the European Union, 2022). Documents from the European Union and international organizations (e.g., OECD, UNESCO) highlight the importance of lifelong learning as a strategic tool for enhancing

[*] Corresponding author: simona.polonyova@euba.sk

workforce adaptability and responding to the megatrends of the 21st century (Council of the European Union, 2022; European Commission, 2021c; OECD, 2023; UNESCO, 2022; UNESCO, 2023).

The 21st-century education system requires a rethinking of various areas of learning to ensure quality education that meets the growing needs of society (Ironsi & Ironsi, 2025). In response to new challenges and needs, the concept of microcredentials has come to the fore as an innovative tool (European Commission, 2021a; European Commission, 2021b) that enables individuals to quickly and purposefully develop specific skills. According to the Brookings research group, microcredentials can benefit people of all ages, educational backgrounds, and origins (Masterson, 2022).

Compared to traditional educational programs, they can reduce the risks associated with mismatches between skills and labour market needs and contribute to the efficiency of the labour market. For employers, microcredentials represent an opportunity to align employee competencies with business needs. For employees, they increase employability and adaptability. According to the 2025 report by the Lumina Foundation, 94 % of students indicated that they are willing to obtain microcredentials recognised as credit-bearing within their study programs, reflecting a growing interest in such forms of learning (Lumina Foundation, 2025).

From a managerial perspective, the skills gap represents not only a challenge for employees but also a strategic issue for organizations. Companies face rising recruitment and training costs, reduced productivity, and difficulties in maintaining competitiveness in global markets. Effective human capital management therefore becomes one of the key factors influencing organizational performance. In this context, microcredentials can be understood as a management tool that supports workforce development and long-term competitiveness.

In the context of an aging population, microcredentials offer an important opportunity for older workers to maintain their employability. Given that traditional forms of education are often time-consuming and financially demanding, microcredentials can also provide older workers with more opportunities to adapt to technological and organizational changes through short, specialized courses or modules. This reality supports active aging and longer participation in the labour market.

The aim of this paper is to present the potential of microcredentials as a tool for fostering lifelong learning within a digital and flexible educational environment and to identify emerging trends in the use of microcredentials from the perspective of educational policy, practice, and human resource management.

1.1 The importance of microcredentials for the development of lifelong learning

Microcredentials are playing an increasingly significant role in lifelong learning, as they offer highly flexible and personalized learning opportunities that enable individuals to quickly update their skills or acquire new competencies in response to labour market demands.

One of the main advantages of microcredentials is their more targeted nature compared to macrocredentials, which are traditionally linked to comprehensive educational programs that cover a broad spectrum of knowledge, transferable skills, or professional competencies and often take several years to complete (Thi Ngoc Ha et al., 2022; Department of Education, Skills and Employment, 2021; Oliver, 2022).

The growing importance of microcredentials emerged during the COVID-19 pandemic. During the pandemic, traditional universities faced a complete halt to in-person teaching, whereas open and distance learning universities were able to continue delivering their programs digitally. A key lesson from the lockdown was that higher education institutions began to implement online programs (Raghavan, Subramaniam, & Awang, 2025).

Microcredentials represent a form of recognized proof of learning outcomes achieved through short learning activities. Their goal is not to replace traditional qualifications but to complement and expand them within diverse educational contexts (Council of the European Union, 2022). In this way, they become a key element of modern lifelong learning strategies. Given their potential to respond to current labour market needs, enhance employability, and increase educational accessibility, microcredentials are becoming an important component of education policy in the European context.

Although short-term accredited courses have existed in various forms for many years, only recently have universities begun to systematically incorporate microcredentials into their offerings. These courses typically serve as preparatory or supplementary education to full bachelor’s or master’s degree programs and are rarely fully integrated into core curricula (Ferguson, 2025).

Microcredentials can encompass various forms of learning activities and recognition. Among these are digital badges, which represent an online form of skills and competency recognition backed by clear evidence (Alt, 2021). They also include industry/professional certifications issued by professional associations or sectoral organizations based on examination processes and demonstration of the knowledge, skills, and abilities required for specific occupations (Boo & Kim, 2020; Thi Ngoc Ha et al., 2022).

It is also important to note that although the use of microcredentials in the European context is gradually increasing, a unified framework for their implementation at the European Union level has been lacking until recently. This gap was addressed in 2022 with the adoption of the Council Recommendation of 16 June 2022 on a European approach to microcredentials for lifelong learning and employability, which established a common definition. According to this definition, a microcredential is a record of learning outcomes that a learner has acquired following a small volume of learning. These learning outcomes are assessed against transparent and clearly defined standards. Upon completing a course, learners acquire specific knowledge, skills, and competencies that reflect societal and labour market needs. They can be shared and are portable. They may stand alone or be combined into larger credentials. In this regard, the Recommendation also set out common European standard elements that describe a microcredential (European Commission, 2021d). This common European approach to the development and use of microcredentials is desirable, as it can significantly enhance their transparency and cross-border comparability.

2. Methods

From a methodological perspective, this paper is based on desk research and relies on a systematic analysis of scientific literature as well as documents and reports from European and international organizations. The research focuses on two closely related areas: (1) mapping the current perception of microcredentials in the context of lifelong learning, and (2) identifying new trends related to microcredentials. To achieve the aim of the paper, we formulated two research questions:

RQ1: What are the emerging trends in microcredentials within lifelong learning?
RQ2: Based on the analysis of documents and scientific literature, how can the main potentials of microcredentials be categorized?

The intention was to provide an evidence-based overview of the current state of knowledge in the field. For the purposes of this paper, a systematic literature review was conducted, involving the search, selection, and analysis of relevant publications based on a predetermined time criterion (publication years 2020 - 2025), which allowed us to capture the evolution of the discourse over time. The systematic analysis of sources consisted of the following steps:

- *Search for relevant sources:* To address the research question, reputable scientific databases were used, and a systematic analysis of scientific literature, documents, and reports from European and international organizations (European Union, UNESCO, OECD, CEDEFOP, and the World Economic Forum) was carried out. Particular attention was given, as noted above, to publications from the period 2020 to 2025 in order to reflect current trends and discussions in the research area.
- *Selection of publications:* Based on the predefined criterion (time criterion: year of publication; relevant scientific articles, documents, and reports were included).
- *Content analysis:* Publications were analyzed with a focus on identifying the potentials of microcredentials, their practical applications, and defining current trends.

3. Results

Microcredentials are not a completely new phenomenon. They have been used for decades in various countries and educational sectors, for example in IT and healthcare. Nevertheless, in many countries, a unified official definition or consistent terminology for the term "microcredential" is still lacking (they are often referred to differently, e.g., as microqualifications, partial qualifications, or module certificates). It is important to note, however, that several countries already apply them in ways that partially or fully correspond to the definition derived from the Council Recommendation of 16 June 2022 (Cedefop, 2022).

From a developmental perspective, it can be stated that microcredentials are currently undergoing significant changes in their structure, format, and intended use (Cedefop, 2022). This dynamic is further

supported by our analysis of the reviewed documents and reports, from which we were able to identify emerging trends in the area of microcredentials. The following trends underscore their growing role as a strategic tool to support lifelong learning and enhance employability within the European Union:

- **Diversification of areas of application** - Microcredentials are no longer used solely as supplementary training in specific sectors (such as IT and healthcare); they are increasingly integrated into higher education, vocational education, and lifelong learning.
- **Transition to digital formats and platforms** - With the advancement of digital technologies, there is a shift from traditional paper-based formats to digital formats.
- **Harmonization of definitions of microcredentials** - The 2022 Council Recommendation signals an effort to align national definitions with the European framework for microcredentials and to strengthen mutual recognition.
- **Shift in intended use** - Microcredentials are being incorporated into higher education, vocational education, and lifelong learning to quickly develop targeted skills and as a tool for reskilling and upskilling various population groups.

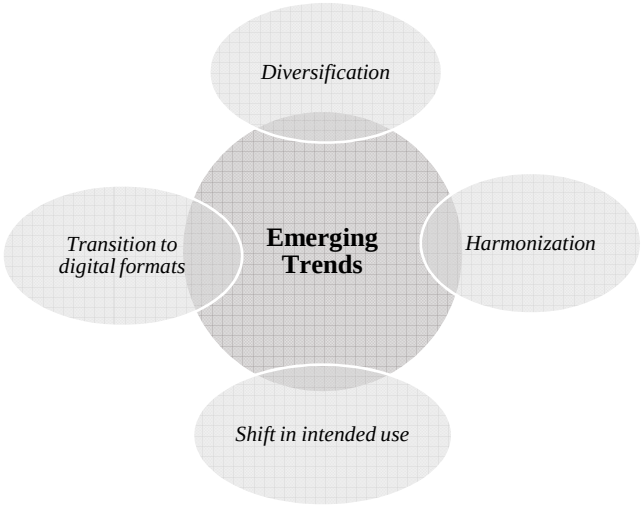

Figure 1. Emerging Trends in Microcredentials
Source: own processing (2025)

An analysis of relevant documents and reports concerning microcredentials in the context of lifelong learning and workforce adaptability has made it possible to identify several key potential benefits. These benefits have been systematically classified into three key dimensions: flexibility, inclusivity, and transferability. The *flexible potential* of microcredentials enables educational programs to respond quickly to changing employer demands in the labour market. Their *inclusive potential* refers to providing access to education for a broader segment of the population, including older individuals and other disadvantaged and vulnerable groups (e.g., persons with disabilities, individuals with low levels of qualification, minorities, and migrants). The *transferable potential* of microcredentials refers to their recognition and transparency among employers, educational institutions, and policymakers. However, this potential requires mutual coordination and collaboration between these actors.

4. Discussion

Microcredentials can make a significant contribution to achieving the European Union's main target indicators set for 2030, which include ensuring that at least 60 % of the adult population participates annually in vocational education and training, and reaching an employment rate of at least 78 %. In this context, however, it is essential that policymakers perceive microcredentials not merely as an innovation but as an integral part of a comprehensive lifelong learning ecosystem that reflects demographic changes, supports digital transformation, and fosters an inclusive approach for all population groups (Council of the European Union, 2022).

Although microcredentials offer considerable potential, their implementation faces challenges related to standardization, recognition (both cross-sectoral and cross-border), and quality assurance. These three

aspects are critical prerequisites for establishing the credibility and value of microcredentials in the labour market. Addressing them ensures that microcredentials will not remain fragmented solutions but will instead become an important systemic tool for supporting the development of lifelong learning and workforce adaptability.

One of the main challenges that needs to be overcome is to ensure that governments recognize microcredentials as legitimate and accepted learning pathways that can lead to the attainment of equivalent education. Such acceptance is essential so that students can transfer their microcredentials between educational institutions without having to repeat the same courses (World Economic Forum, 2022). The European Qualifications Framework, as a common standard reference framework for transparency, portability, and comparability, is open to microcredentials provided they are first integrated into national qualifications frameworks (Council of the European Union, 2022).

Successful implementation of microcredentials in practice requires robust institutional process management. Key actions include the regular evaluation of institutional educational programs, analysis of stakeholder needs, assessment of the effectiveness of individual learning programs, and monitoring the satisfaction of educational stakeholders. Equally important is using the results of these evaluations to analyze the achievement of set objectives, identify areas for improvement, and strengthen the satisfaction of all stakeholders involved (Rodríguez-Mantilla, Martínez-Zarzuelo, & León-Carrascosa, 2025). To maximize the potential of microcredentials, it is essential to promote their wider uptake and popularization among employers, educational institutions, and individuals. A crucial step in achieving this objective is the active involvement of industry and professional associations, working in collaboration with educational institutions, in the process of developing and recognizing microcredentials (Thi Ngoc Ha, Van Dyke, Spittle, Watt, & Smallridge, 2024).

Conclusion

Microcredentials play a significant role in adult education, as they make it possible to recognise and document acquired competencies, including in areas related to emerging labour market and societal needs, such as digitalisation, automation, and technological change (Cedefop, 2022). In these areas, formal qualifications may be lacking, or - if they do exist - obtaining them often requires several years of study. Given that practice often demands these competencies immediately, microcredentials offer a flexible and rapid means to acquire and verify specific (usually narrowly defined) specialised skills. Microcredentials enable the precise documentation of acquired competencies, expressed in the European Credit Transfer and Accumulation System (ECTS). From the perspective of further educational development, microcredentials thus represent a significant step forward.

Current discussions on the role of microcredentials in education and the labour market are ongoing, and expert opinions vary. In general, however, microcredentials are not perceived as a replacement for formal education systems. They are primarily intended for adults who already possess a certain qualification, work experience, or both. Microcredentials can be considered a complementary tool that enhances the formal education system’s capacity to respond flexibly to dynamic labour market changes. However, there is still an ongoing debate on how formal education systems and microcredentials can effectively collaborate (Cedefop, 2022).

These characteristics of microcredentials acquire particular importance in the context of current trends identified in this paper. Firstly, there is a clear diversification in the areas of their application: microcredentials are no longer limited to specific sectors but are increasingly being integrated into higher education, vocational education, and lifelong learning. Secondly, there is a shift from traditional paper-based formats to digital platforms, which enhances their accessibility and flexibility. Moreover, the harmonisation of microcredential definitions, supported by the EU Council Recommendation of 2022, represents a step towards aligning national frameworks with the European system and strengthening mutual recognition. However, it is essential to emphasise that the harmonisation of definitions is only the first step towards their full integration into educational and qualification systems. Prior to this, their development at the national level is crucial, requiring a coordinated and harmonised approach among the country’s education providers. Microcredentials need to be linked to national qualification frameworks to facilitate their subsequent integration into the European Qualifications Framework. Such linkage is key to ensuring their recognition not only at the national but also at the European level, thereby supporting labour mobility within the European labour market. This process requires close cooperation between public institutions, educational institutions, and employers. Equally important is the systematic promotion

of awareness among employers and their involvement in defining needs and expectations, in order to identify areas where micro-credentials can most effectively support employability and workforce development. In addition, it is essential to raise awareness of microcredentials among the general public. Individuals should be informed about the possibility of obtaining microcredentials, their utility in the labour market, and the concrete procedures by which they can acquire or expand them. Closely related to this is the existence of publicly accessible databases that can serve as information sources for all those interested in upgrading or complementing their qualifications - not only for job seekers but also for those wishing to continuously develop their skills or considering a career change. Microcredentials thus become a tool not only for rapidly acquiring specific skills but also for retraining and developing skills for various population groups.

Do Social Issues Matter? A Survey on Socially Responsible Behaviour of Businesses in the Czech and Slovak Republics

***Renata* Skýpalová[1,*], *Mária* Urbánová[2], and *Martin* Šikýř[1]**

[1] AMBIS University, Department of Management and Human Resources, Praha, Czech Republic
[2] Slovak University of Agriculture, Institute of Economics and Management, Nitra, Slovakia

Abstract

Research background: The socially responsible behaviour of businesses within their corporate social responsibility (CSR) activities can benefit both the businesses themselves as well as the communities affected by their operation. However, socially oriented efforts can be very costly, and the involvement of businesses in them can vary significantly.
Purpose of the article: The paper investigates the socially responsible behaviour of a sample of businesses in the Czech and Slovak Republics to evaluate the involvement of surveyed businesses in social issues and to identify the factors that differentiate the involvement.
Methods: The investigation comes out of a questionnaire survey of representatives of twice a hundred businesses in the Czech and Slovak Republics declaring CSR efforts within their operations. The Czech and Slovak Republics were chosen as representatives of developed market economies of Central Europe with strong political, economic, and social relations. The data were processed and hypotheses were verified using selected statistical tests, such as Cronbach's alpha validity test, Shapiro-Wilk test of normality, and Kruskal-Wallis H test.
Findings & Value added: The findings confirmed the involvement of surveyed businesses in various social issues, such as respect for equal opportunities in the workplace, application of principles of business ethics, support of the work-life balance of employees, or public rejection of child labour. The business size and scope of operations were identified as factors differentiating the involvement of surveyed businesses in particular social issues. The findings are beneficial for the surveyed and other businesses involved in CSR efforts. To achieve expected CSR benefits, surveyed businesses should apply a more strategic approach to socially responsible behaviour.

Keywords: Corporate social responsibility, Social pillar, Stakeholder communities, Czech Republic, Slovak Republic

JEL classification: D20, M1, O30

1. Introduction

The concept of corporate social responsibility (CSR) within the business environment promotes socially, environmentally, and economically oriented efforts of businesses to achieve sustainable economic prosperity concerning human well-being and nature conservation (Grzegorczyk, 2022). Following socially, environmentally, and economically responsible behaviour has become both a legal obligation and a business necessity for businesses (Rosak-Szyrocka et al., 2022). More and more stakeholders, from government institutions through business partners to final customers, expect businesses to be socially, environmentally, and economically sustainable (Hosta & Zabkar, 2021). Targeted socially, environmentally, and economically oriented efforts determine public interest in businesses as such and thereby determine their competitiveness and profitability (Catalao-Lopes et al., 2023).

Being socially responsible means being concerned with social issues related to people and their living and working conditions to ensure that people are treated well and fair (Urbancova & Vrabcova, 2020). Being environmentally responsible means being concerned with environmental issues related to the planet and its animate and inanimate nature to ensure the effective and efficient use of natural

[*] Corresponding author: renata.skypalova@ambis.cz

resources concerning future generations (Zhang et al., 2021). Being economically responsible means being concerned with economic issues related to the profitability of businesses and their business models to ensure prosperous operations concerning sustainable competitiveness (Waniak-Michalak et al., 2018).

The involvement of businesses in social, environmental, and economic issues needs to be balanced, not to challenge the profitability of businesses, but at the same time, benefit people and the planet (Isacowitz et al., 2022). In other words, the socially, environmentally, and economically responsible behaviour of businesses needs to be both rational and voluntary. Businesses must be aware that society expects their social, environmental, and economic involvement (Vveinhardt & Sroka, 2021). However, particular socially, environmentally, and economically oriented efforts must be incorporated into business strategies voluntarily and have to bring rational benefits to the majority of stakeholders (Mukherjee & Nunez, 2019).

On the one hand, efforts towards socially responsible behaviour bring many benefits to businesses, such as a better image, satisfied customers, and engaged employees, but on the other hand, they require investing a lot of time, money, and energy. In other words, businesses may have different motives for acting socially responsibly. For this reason, the involvement of businesses in socially responsible behaviour can be significantly different. Therefore, the paper investigates the socially responsible behaviour of a sample of businesses in the Czech and Slovak Republics to evaluate the involvement of surveyed businesses in social issues and to identify the factors that differentiate the involvement. For these purposes, two research questions are defined:

RQ1: Which social issues indicate the strongest involvement of surveyed businesses?

RQ2: Which factors differentiate the involvement of surveyed businesses in social issues?

The Czech and Slovak Republics were chosen as representatives of developed market economies of Central Europe with strong political, economic, and social relations founded on the history of the common state (Fitzova & Zidek, 2015). They have been independent states since 1993 and member states of the European Union since 2004. Politically, economically, and socially, they benefit from cooperation among themselves as well as with their neighbours, such as Germany, Austria, Poland, or Hungary. Their membership in the European Union leads to compliance with specific political, economic, and social initiatives promoting social, environmental, and economic responsibility (Kazharski, 2019). Such initiatives impact particular businesses that need to behave socially responsibly to meet all political, economic, and social obligations to stakeholders, such as government institutions, outside investors, business partners, inside employees, direct customers, or local communities (Brozyna et al., 2020). Investigating the involvement of businesses in social issues and factors differentiating the involvement of businesses in social issues meets the research gap within the CSR research. The paper contributes to the findings of existing research studies on CSR efforts by focusing specifically on the social issues of different businesses in different political, economic, and social environments, which could be beneficial for other researchers and practitioners involved in CSR issues.

Within the paper, first, a literature review on CSR issues and factors affecting the involvement of businesses in them is presented. Second, the way of investigating the involvement of businesses in the Czech and Slovak Republics in social issues and factors differentiating the involvement of businesses in social issues is described. Third, the authors' research results on the socially responsible behaviour of businesses in the Czech and Slovak Republics are presented and discussed. Finally, conclusions about the authors' research findings and proposals are made.

2. Literature review

Research on corporate social responsibility (CSR) has long been popular all over the world. Researcher studies focus on the overall CSR systems (Khan et al., 2020) as well as on particular CSR issues (Velte and Stawinoga, 2020) within various businesses sorted by business size (small, medium-sized, large), area of operations (production, trade, services), or scope of operations (local, national, international).

The findings of most research studies confirm the constantly increasing involvement of various businesses across business sizes, areas of operations, or scopes of operations in many social, environmental, and economic issues (Javed & Husain, 2021). The most common motive for CSR efforts is the improvement of the business brand (Wei & Jung, 2022). From a business size, area of operations, or scope of operations perspective, investment in CSR efforts is most common in large service-oriented businesses operating in international markets (Heath et al., 2023). These businesses invest the most in CSR efforts that bring the greatest value to stakeholders, primarily customers and employees (Zhao et al., 2021). These stakeholder groups mean the most to business development. They are the source of required

know-how and needed profitability (Lee et al., 2018). The concern for the well-being of customers means offering quality goods and services or building good customer relationships (Olsanova et al., 2021). The concern for the well-being of employees means creating a safe and healthy working environment, preventing discrimination in the workplace, providing equal job opportunities, supporting people with disabilities, applying flexible working arrangements, or promoting work-life balance (Guzzo et al., 2022). These and similar concerns about customers, employees, and other communities represent social issues within business CSR efforts.

In the Czech Republic, for example, Paulik et al. (2015) examined the application of the CSR concept in commercial banks in the Czech Republic using a sample of the four largest commercial banks according to the number of customers and considering social, environmental, and economic issues. They revealed an average involvement of surveyed commercial banks in CSR efforts and confirmed no significant association between CSR efforts and the financial performance of surveyed commercial banks. Bartok (2018) analysed the impact of CSR on e-commerce small and medium-sized businesses in the Czech Republic using a sample of sixty-three businesses and revealing a positive association between the implementation of CSR and sales, as customers prefer businesses with beneficial CSR efforts. Kostalova and Tetrevova (2018) examined whether sugar-producing businesses in the Czech Republic use the option of co-financing their socially, environmentally, and economically oriented CSR efforts from EU funds. They found out that only two out of five surveyed sugar-producing businesses used the option in the 2007-2013 programming period. The main barrier was the lack of know-how in project management. Macgregor et al. (2020) analysed the perception of corporate social responsibility by front-line employees of luxury fashion businesses in Prague, Czech Republic, using a sample of ten top businesses. They uncovered a lack of awareness and involvement of front-line employees in CSR issues, which leads to not meeting the benefits of CSR efforts. Vrabcova and Urbancova (2021) surveyed representatives of one hundred and seventy-nine businesses and interviewed representatives of eight agricultural businesses in the Czech Republic to compare the approaches of selected businesses to the issue of corporate social responsibility and identify the main factors of their competitiveness. They concluded that selected businesses pay attention to process orientation, industry stability, and financial performance, together with quality relationships with stakeholders. Strihavkova et al. (2021) surveyed an awareness of the corporate social responsibility of businesses in the Usti nad Labem Region in the Czech Republic using a sample of fifty-two small and medium-sized businesses. They found a lack of information about the CSR principles, impacts, and benefits across surveyed businesses, as well as a lack of involvement of employees in the CSR efforts of surveyed businesses. The most frequently perceived issue of voluntarily implemented CSR efforts was the difficulty of measuring financial effects. Fuchsova (2022) investigated whether businesses with a strategic approach to CSR achieve better economic results than businesses with a rather intuitive approach to CSR using a sample of 404 businesses in the Czech Republic declaring CSR efforts. The findings revealed a positive association between a strategic approach to CSR and achieved economic results. Implemented CSR strategies resulted in positive impacts on employees and local communities.

In the Slovak Republic, for example, Ubreziova and Moravcikova (2017) analysed the involvement of agricultural-food businesses in the Slovak Republic in CSR issues using a sample of eighty-one businesses. They confirmed low awareness of the surveyed businesses of CSR principles and practices. However, more than two-thirds of surveyed businesses declared CSR efforts in line with their business strategies. The strongest motive of surveyed businesses for CSR efforts was the improvement of their business reputation. Nadanyiova et al. (2020) surveyed differences in the perception of green marketing within environmentally responsible communication by different generations of customers in the Slovak Republic using a sample of two thousand thirty-five respondents. They confirmed a strong perception of green marketing and environmental responsibility by customers across generations. They also identified many benefits of environmentally responsible behaviour of businesses, from improving the business brand through attracting relevant investors to gaining a sustained competitive advantage. Tesovicova and Krchova (2022) analysed the association between the involvement in environmentally responsible efforts and the business size using a sample of five hundred and forty-four businesses operating in the Slovak Republic. They revealed the strongest involvement in environmentally responsible efforts in large businesses, which were mostly concerned with regional rather than global environmental issues. Igarova et al. (2023) surveyed how CSR efforts serve as a marketing tool for food businesses towards their customers in the Slovak Republic using a sample of one thousand two hundred and fifty-four respondents. They concluded that customers are generally familiar with the CSR efforts of food businesses, although

many would need more detailed information. It follows that food businesses should communicate their CSR efforts more actively. Customers mostly perceived the CSR efforts of food companies as a marketing tool, creating a positive business brand, which can attract and keep satisfied customers and so ensure sustainable competitiveness and profitability.

In international comparison, for example, Matysik-Pejas and Horska (2018) surveyed awareness of customers of CSR efforts of food businesses using samples of customers from Slovakia (two hundred and seventy-nine respondents) and Poland (two hundred and seventy-two respondents). They uncovered that both customers in Slovakia and Poland consider employee-oriented social issues to be the most important CSR efforts, including meeting legal obligations, ensuring open and honest communication, and improving the economic situation of employees. They confirmed that customers and employees represent the most important stakeholder groups affected by CSR efforts. If they do not satisfy the needs of customers and employees, it is difficult to develop the business reputation and achieve other CSR benefits. Krajnakova et al. (2018) analysed the association between economic conditions and the development of CSR activities using a sample of businesses in Slovakia, Lithuania, Latvia, and Estonia. They confirmed that changes in economic conditions may significantly impact the development of CSR activities in businesses. However, even in times of worse economic conditions, businesses may continue to invest in CSR activities to achieve long-term CSR benefits. Çera et al. (2020) investigated whether CSR efforts are affected by business size and age using a sample of eight hundred and twenty-two small and medium-sized businesses in the Czech Republic (four hundred and fifty-four businesses) and in the Slovak Republic (three hundred and sixty-eight businesses). They revealed that the CSR concept is not perceived similarly in both countries. They found no significant association between CSR efforts and business size. However, they found a significant association between CSR efforts and business age, namely in businesses in the Slovak Republic, where the older businesses were less involved in CSR efforts. Gavurova et al. (2022) analysed differences in CSR practices of micro, small, and medium-sized businesses in the V4 countries (Czechia, Slovakia, Poland, and Hungary). Their findings uncovered that CSR strategies were most used by businesses in Slovakia, Poland, and Hungary, in contrast to businesses in Czechia. The implementation of particular CSR practices was more common in agriculture or tourism than in manufacturing, construction, retail, or services. Managers of businesses confirmed the most important benefits of implementing CSR practices to be improving business reputation, gaining business contracts, and building a competitive advantage. The business size was found to be significant in the perception of the business as CSR-oriented. Medium-sized businesses were more likely to be perceived as CSR-oriented than small and micro businesses.

There are, of course, many other CSR surveys conducted in the Czech, Slovak, and international frameworks. However, most of them bring comparable results confirming that CSR efforts of businesses must be a voluntary, but strategic matter to bring relevant social, environmental, and economic effects to all stakeholders. In addition, certain factors such as business sizes, areas of operations, or scopes of operations affect the involvement of businesses in CSR issues.

3. Methods

The investigation of the socially responsible behaviour of a sample of businesses in the Czech and Slovak Republics comes out of a questionnaire survey of representatives of 100 businesses in the Czech Republic and 100 businesses in the Slovak Republic declaring CSR efforts within their operations. The questionnaire survey was carried out in the period January-November 2023 within the project supported by the Visegrad Fund (no. 22220149). Representatives of surveyed businesses were contacted by email, receiving a link to an online questionnaire, and included executive directors, CSR, HR, or PR managers, and other line managers. The selection of surveyed businesses was motivated by the desire to achieve a fairly equal number of businesses by business size, area of operations, and scope of operations.

The whole online questionnaire included five sections consisting of fifty-three questions researching current CSR practices in surveyed businesses. For this paper, three sorting questions and ten specific questions related to the involvement of surveyed businesses in social issues within their CSR efforts were chosen. The three sorting questions are related to (1) business size (small: 0-49 employees, medium-sized: 50-249 employees, large: 250+ employees), (2) area of operations (production, trade, services), and (3) scope of operations (one region, more regions, whole country). The ten specific questions are related to (A) respect for equal gender, age, and other opportunities in the workplace, (B) support of voluntary activities of employees, (C) application of principles of business ethics, (D) philanthropy and

sponsorship, (E) support of local communities, (F) care for employees beyond legal obligations, (G) training and development of employees beyond legal obligations, (H) assistance to dismissed employees beyond legal obligations, (I) support of the work-life balance of employees, (J) public rejection of child labour. The numbers and letters are used in the text to identify particular sorting characters and social issues. The involvement of surveyed businesses in particular social issues was evaluated on the scale very strongly, strongly, average, negligible, and not at all.

Table 1 describes the samples of businesses in the Czech and Slovak Republics sorted by business sizes (small, medium-sized, large), area of operations (production, trade, services), and scope of operations (one region, more regions, whole country). The samples of businesses in the Czech and Slovak Republics are more or less comparable, although the Czech Republic sample is dominated by service-oriented businesses, while the Slovak Republic sample is dominated by production-oriented businesses.

Table 1. The samples of businesses in the Czech and Slovak Republics

		The Czech Republic (N = 100)	The Slovak Republic (N = 100)
Business size	Small	40%	40%
	Medium-sized	20%	20%
	Large	40%	40%
Area of operations	Production	22%	39%
	Trade	45%	35%
	Services	33%	26%
Scope of operations	One region	37%	41%
	More regions	31%	37%
	Whole country	32%	22%

Source: authors (2025)

The data were processed and examined using selected statistical tests and the statistical application XLSTAT. The variables chosen were subjected to Cronbach's alpha validity test. Cronbach's alpha was created by Cronbach (1951) to quantify the internal consistency of a test or scale. It is represented as a number between 0 and 1. Internal consistency is a measure of how closely all of the test's items measure the same idea or construct, and it is thus related to how closely the test's items are related to one another. As a general rule, a Cronbach's alpha of 0.70 and above is considered good, 0.80 and above to be better, and 0.90 and above to be the best (Statistics Solutions, 2024). The Shapiro-Wilk test was done to compare the scores in the sample to a normally distributed set of scores with the same mean and standard deviation. Both the alternative and the null hypotheses, which assert that the variable from which the sample was taken has a normal distribution, were established. The alternative hypothesis assumes that there is a non-normal distribution of the variable from which the sample was taken. The null hypothesis was defined with the assumption that there would be some variations among businesses in their involvement in specified social issues. Three hypotheses were established and examined using a non-parametric Kruskal-Wallis statistical test (Kruskal and Wallis, 1952) following selected variables. When comparing more than two independent samples, this test works well as a generic nonparametric test (Ostertagova et al., 2014):

H0: Social issues indicated by variables A-J are not different among surveyed businesses.

H1: Social issues indicated by variables A-J are significantly different among surveyed businesses according to the business size.

H2: Social issues indicated by variables A-J are significantly different among surveyed businesses according to the area of operations.

H3: Social issues indicated by variables A-J are significantly different among surveyed businesses according to the scope of operations.

The data examination included a comparison of the relative frequencies of responses on the country, business size, area of operations, and scope of operations.

4. Results

The socially responsible behaviour of 100 businesses in the Czech Republic and 100 businesses in the Slovak Republic is investigated to find out which social issues indicate the strongest involvement of surveyed businesses (RQ1) and which factors differentiate the involvement of surveyed businesses in social issues (RQ2).

The data examination uncovered that not many of the surveyed businesses in the Czech Republic (27%), as well as in the Slovak Republic (43%), strategically plan their CSR efforts. In the Czech Republic, these are mostly large businesses (59%) operating in services (44%) or trade (38%) and in the whole country (50%) or more regions (38%). Only 41% of small and medium-sized businesses, regardless of their area or scope of operations, confirmed the strategic planning of their CSR efforts. In the Slovak Republic, these are mostly large businesses (72%) operating in production (55%) and in more regions (45%). Only 28% of small and medium-sized businesses, regardless of their area or scope of operations, confirmed the strategic planning of their CSR efforts. Strategic planning is standard in large businesses. However, small and medium-sized businesses, regardless of their area or scope of operations, should also strategically plan their CSR efforts to deliver valuable outcomes.

From the perspective of particular social issues within CSR efforts, in the Czech Republic, surveyed businesses declared strong involvement in (A) respect for equal gender, age, and other opportunities in the workplace (51%), (C) application of principles of business ethics (47%), and (J) public rejection of child labour (47%). On the other hand, surveyed businesses declared no involvement in (H) assistance to dismissed employees beyond legal obligations (27%), (E) support of local communities (20%), and (B) support of voluntary activities of employees (14%). In comparison, in the Slovak Republic, surveyed businesses declared strong involvement in (J) public rejection of child labour (60%), (A) respect for equal gender, age, and other opportunities in the workplace (57%), (C) application of principles of business ethics (54%). On the other hand, surveyed businesses declared no involvement in (H) assistance to dismissed employees beyond legal obligations (27%), (B) support of voluntary activities of employees (11%), and (E) support of local communities (11%).

Table 2 sums up the strongest involvement of surveyed businesses in particular social issues (A-J) according to the country (the Czech Republic, the Slovak Republic), business size (small, medium-sized, large), area of operations (production, trade, services), and scope of operations (one region, more regions, whole country). The data examination revealed that most surveyed businesses are more or less involved in all of the social issues (A-J). However, in the Czech Republic, the strongest involvement in particular social issues is mostly represented by small, service-oriented, and whole country-oriented businesses. On the other hand, in the Slovak Republic, the strongest involvement in particular social issues is mostly represented by large, production-oriented, and one-region-oriented businesses. This could indicate some differences between countries and businesses.

Table 2. The strongest involvement of surveyed businesses in particular social issues

	The Czech Republic			**The Slovak Republic**		
Social Issues	**Business Size**	**Area of Operations**	**Scope of Operations**	**Business Size**	**Area of Operations**	**Scope of Operations**
A	Small	Services	More regions	Large	Production	One region
B	Small	Services	Whole country	Large	Trade	One region
C	Small	Services	More regions	Large	Production	One region
D	Large	Services	Whole country	Large	Services	More regions
E	Small	Services	Whole country	Large	Production	One region
F	Small	Services	More regions	Large	Production	One region
G	Large	Services	Whole country	Large	Production	One region
H	Medium-sized	Services	Whole country	Large	Production	One region
I	Small	Services	One region	Large	Production	One region
J	Small	Services	Whole country	Small	Trade	One region

(A) Respect for equal gender, age, and other opportunities in the workplace
(B) Support of voluntary activities of employees
(C) Application of principles of business ethics
(D) Philanthropy and sponsorship
(E) Support of local communities
(F) Care for employees beyond legal obligations
(G) Training and development of employees beyond legal obligations
(H) Assistance to dismissed employees beyond legal obligations
(I) Support of the work-life balance of employees
(J) Public rejection of child labour

Source: authors (2025)

Differences in the involvement of surveyed businesses in particular social issues indicated by variables A-J were tested according to the business size, area of operations, and scope of operations using a non-parametric Kruskal-Wallis statistical test. Before a test is used for study or examination, its internal consistency needs to be established to guarantee its validity (Tavakol and Dennick, 2011). Cronbach's alpha was computed for this reason, and a validity of 0.817 indicates acceptable validity. For every variable, the Shapiro-Wilk test returns a computed p-value less than the significance alpha=0.05 and a risk of less than 0.01% for rejecting the null hypothesis H0 when it is true. The alternative hypothesis—that the variable from which the sample was taken did not follow a normal distribution—is accepted since the Shapiro-Wilk test indicates that the distribution is non-normal (see Table 3).

Table 3. Cronbach's alpha and Shapiro-Wilk test

Variable\Test	Cronbach's alpha	Shapiro-Wilk
For all the tested variables	0.817	< 0.0001

Source: authors (2025)

Hypothesis H1 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the business size was proved for the Czech Republic in several variables (see Table 4), namely (D) philanthropy and sponsorship, (H) assistance to dismissed employees beyond legal obligations, (I) support of the work-life balance of employees, and (J) public rejection of child labour. The involvement of surveyed businesses in these social issues differs significantly according to the business size, which means that surveyed businesses of different sizes deal with these social issues differently. This makes the factor of business size fairly important when examining the involvement in social issues within CSR efforts.

Hypothesis H2 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the area of operations was not proved at all for the Czech Republic and was rejected completely.

Hypothesis H3 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the scope of operations was proved for the Czech Republic only in two variables, namely the (D) philanthropy and sponsorship, and (E) support of local communities.

Table 4. Kruskal-Wallis test for surveyed businesses in the Czech Republic

Variable\Test	(1) Business Size	(2) Area of Operations	(3) Scope of Operations
(A) Respect for equal gender, age, and other opportunities in the workplace	0.074	0.225	0.150
(B) Support of voluntary activities of employees	0.428	0.839	0.743
(C) Application of principles of business ethics	0.212	0.325	0.221
(D) Philanthropy and sponsorship	**0.028**	0.485	**0.012**
(E) Support of local communities	0.414	0.185	**0.036**
(F) Care for employees beyond legal obligations	0.267	0.998	0.115
(G) Training and development of employees beyond legal obligations	0.162	0.218	0.493
(H) Assistance to dismissed employees beyond legal obligations	**0.011**	0.888	0.542
(I) Support of the work-life balance of employees	**0.011**	0.980	0.272
(J) Public rejection of child labour	**0.023**	0.680	0.436

Source: authors (2025)

Hypothesis H1 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the business size was proved for the Slovak Republic in half of the variables (see Table 5), namely (C) application of principles of business ethics, (E) support of local communities, (G) training and development of employees beyond legal obligations, (H) assistance to dismissed employees beyond legal obligations, and (I) support of the work-life balance of employees. The last two –(H) assistance to dismissed employees beyond legal obligations and (I) support of the work-life balance of employees – are significant in both countries. This confirms that the factor of business size is important when examining the involvement in social issues within CSR efforts.

Hypothesis H2 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the area of operations was proved for the Slovak Republic in two variables, namely (F) care for employees beyond legal obligations and (H) assistance to dismissed employees beyond legal obligations. This differs from the Czech Republic, where there was no difference revealed.

Hypothesis H3 that social issues indicated by variables A-J are significantly different among surveyed businesses according to the scope of operations was proved for the Slovak Republic only in one variable, namely (D) philanthropy and sponsorship. This is the same as for the Czech Republic, which makes (D) philanthropy and sponsorship an important social issue for surveyed businesses in both countries.

Table 5. Kruskal-Wallis test for surveyed businesses in the Slovak Republic

Variable\Test	(1) Business Size	(2) Area of Operations	(3) Scope of Operations
(A) Respect for equal gender, age, and other opportunities in the workplace	0.273	0.355	0.520
(B) Support of voluntary activities of employees	0.326	0.304	0.447
(C) Application of principles of business ethics	**0.013**	0.292	0.847
(D) Philanthropy and sponsorship	0.106	0.367	**0.042**
(E) Support of local communities	**0.025**	0.288	0.306
(F) Care for employees beyond legal obligations	0.309	**0.017**	0.333
(G) Training and development of employees beyond legal obligations	**0.004**	**0.037**	0.328
(H) Assistance to dismissed employees beyond legal obligations	**0.009**	0.338	0.370
(I) Support of the work-life balance of employees	**0.013**	0.170	0.466
(J) Public rejection of child labour	0.765	0.188	0.540

5. Discussion

The investigation of socially responsible behaviour of 100 businesses in the Czech Republic and 100 businesses in the Slovak Republic uncovered that the strongest involvement of surveyed businesses in particular social issues (RQ1) in both countries indicates (A) respect for equal gender, age, and other opportunities in the workplace, (C) application of principles of business ethics, and (J) public rejection of child labour. Moreover, the comparison revealed significant differences in the involvement of surveyed businesses in particular social issues (RQ2) according to business size (hypothesis H1) in both countries, namely in (H) assistance to dismissed employees beyond legal obligations and (I) support of the work-life balance of employees. This confirms that the factor of business size is fairly important when examining the involvement of businesses in social issues within their CSR efforts.

The factor of the scope of operations could be similarly important. The comparison revealed significant differences in the involvement of surveyed businesses in particular social issues (RQ2) according to the scope of operations (hypothesis H3) in both countries, namely in (D) philanthropy and sponsorship. The factor of the area of operations was found as not so important. The comparison revealed significant differences in the involvement of surveyed businesses in particular social issues (RQ2) according to an area of operations (hypothesis H2) only in the Slovak Republic, namely in (F) care for employees beyond legal obligations and (H) assistance to dismissed employees beyond legal obligations, not in the Czech Republic.

In general, it appears that surveyed businesses display evident CSR efforts involving social issues, which can have many reasons, from following current trends through meeting specific needs to showing pure altruism (Rim & Song, 2017). Factors differentiating the involvement of surveyed businesses in particular social issues are business size and the scope of operations. Certain differences were found in the case of strategic planning of CSR efforts, confirmed mostly only by large businesses operating in services, trade, or production, and in the whole country or more regions. This could mean that most of the other surveyed businesses do not consider CSR efforts as a strategic matter and that they deal with particular social issues ad hoc if worthwhile (Machales & Blanch, 2022). This could be a potential

problem in the long run, as CSR efforts that are not aligned with the business strategy may not bring the expected benefits to both the business and the target stakeholders (Dang et al., 2022).

The findings suggest that any CSR efforts of businesses dealing with social issues could meet the essential purpose of socially responsible behaviour, which concerns the well-being of communities affected by business operations (Attah & Amoah, 2023). This applies in particular to employee communities, in which case businesses could be involved in respect for equal gender, age, and other opportunities in the workplace, training, and development beyond legal obligations, or support of the work-life balance (Kim et al., 2018).

In the case of customers and other communities, businesses should be involved in the application of principles of business ethics, philanthropy, and sponsorship, support of local communities, or public rejection of child labour (von Schnurbein, 2016). Dealing with similar social issues should be motivated by the intention to benefit a wide range of stakeholders while meeting the business needs (Boadi et al., 2018).

Conclusion

The investigation of the socially responsible behaviour of a sample of businesses in the Czech and Slovak Republics aimed to find out which social issues indicate the strongest involvement of surveyed businesses and which factors differentiate the involvement of surveyed businesses in social issues.

The comparison revealed that surveyed businesses are more or less involved in various social issues, such as respect for equal opportunities in the workplace, application of principles of business ethics, support of the work-life balance of employees, or public rejection of child labour. Most of these social issues are related to employee and customer communities that represent the most important stakeholders for the sustainable competitiveness and profitability of businesses. The business size and scope of operations were found as factors differentiating the involvement of surveyed businesses in particular social issues. A potential problem for most surveyed businesses could be a trendy rather than a strategic approach to socially responsible behaviour. Any CSR efforts should be integrated with business strategies to purposefully deliver the best value.

The findings are limited by the focus of the survey only on the Czech and Slovak Republics, as well as by a relatively small number of surveyed businesses of different business sizes, areas of operations, and scopes of operations. On the other hand, the findings contribute to the findings of existing research studies on CSR efforts by focusing specifically on the social issues of different businesses in different political, economic, and social environments represented by the Czech and Slovak Republics. Moreover, the samples of businesses in the Czech and Slovak Republics cover a diverse structure of small, medium-sized, and large businesses operating in production, trade, and services in one or more regions, which is a structure typical of most developed market economies across the European Union. The findings could thus be beneficial for other researchers and practitioners involved in CSR issues to achieve a higher level of socially responsible behaviour.

Further research could be aimed at the reasons businesses have for particular social, environmental, and economic issues within their CSR efforts and their effect on various groups of stakeholders, from investors and business partners through employees and customers to local communities and government institutions. Knowing their specific expectations regarding socially, environmentally, and economically responsible behaviour would be beneficial for more strategic and valuable CSR efforts of businesses.

Acknowledgements

This research and paper were supported within the project “Corporate Social Responsibility in Business Practice of the Visegrad Region (Visegrad Grant no. 22220149)”. The project is co-financed by the Governments of Czechia, Hungary, Poland, and Slovakia through Visegrad

Grants from the International Visegrad Fund. The mission of the fund is to advance ideas for sustainable regional cooperation in Central Europe.

We would like to express our gratitude and acknowledge that this paper represents a segment of a comprehensive study conducted as part of the mentioned project. We extend our appreciation to the project team, funding agencies, and all individuals who contributed to the successful execution of this study.

Abstract

Research background: Human Resource Management (HRM) is undergoing a fundamental transformation, moving from predominantly administrative functions towards a more strategic role within organizations. This shift is driven primarily by digitalization, the integration of HR technologies, and global trends such as skills-based workforce planning, inclusion, and employee engagement. While traditional practices remain important, their effectiveness increasingly depends on technological support and the ability to generate and analyze high-quality data.
Purpose of the article: The article aims to examine the transformation of traditional HRM practices through the lens of digitalization and technology adoption. Specifically, it focuses on identifying the most frequently managed HR functions, the degree of HR software utilization, and the strategic implications of these trends for employee engagement, organizational effectiveness, and competitiveness.
Methods: The research is based on secondary data analysis of the Chartered Institute of Personnel and Development (CIPD) survey conducted among 1,174 HR leaders in the United Kingdom, combined with a systematic review of international academic and practitioner literature published between 2018 and 2024. Comparative analysis, content analysis, and causal interpretation were applied to contextualize the findings within broader global HRM trends and theoretical frameworks of strategic HRM and digital transformation.
Findings & Value added: The results reveal that while HR recruitment and HR information systems remain dominant HR functions, advanced practices such as workforce planning and people analytics are still underutilized. The article adds value by highlighting the gap between the strategic importance of HR activities and their actual technological support, emphasizing the need for data-driven workforce planning and digital integration.

Keywords: Human resource management, Transformation, Digitalization, Practices

JEL classification: M12, M50, M54

1. Introduction

The transformation of human resource management (HRM) is increasingly taking the form of a long-term and continuously evolving process that transcends the traditional understanding of HR as a purely administrative and supportive function. It is becoming a strategic pillar of organizations, tasked not only with securing the necessary resources and competencies but also with creating an environment in which human capital can develop in alignment with the dynamics of the external environment. (Ulrich & Brockbank, 2005; Boxall & Purcell, 2016) In this context, HR management must adapt to technological change, shifting employee expectations, and the growing need to link organizational performance with long-term sustainability. Thus, transformation cannot be understood merely as a set of tools, but a complex approach that integrates processes, culture, and strategies into a unified whole. This evolution involves the integration of advanced digital technologies, including AI and people analytics, which enable data-driven decision-making and personalized employee experiences. It also requires rethinking performance management to emphasize continuous feedback, learning, and adaptability rather than static

[*] Corresponding author: nella.svetozarovova@unipo.sk

annual evaluations. Furthermore, fostering diversity, equity, and inclusion has become an essential component of HR transformation, ensuring that organizational practices support fairness and psychological safety. (Svetozarovová et al., 2023) Ultimately, the transformed HR function acts as a catalyst for innovation, organizational agility, and sustainable competitive advantage.

1.1 The Transformation of Human Resource Management

A key driving force of organizational transformation is digitalization, which fundamentally alters the way organizations operate. The Industry 4.0 concept, associated with automation, the Internet of Things (IoT), augmented reality, and data technologies, creates new frameworks for work management. (Blštáková & Dědečková, 2021) For HR, this implies a shift from traditional personnel processes to so-called digital HRM, where technologies serve as a foundational infrastructure for strategic decision-making, process optimization, and enhancement of employee experience. (Bondarouk & Brewster, 2016) This shift is significant because digitalization is not merely an efficiency tool; it also shapes organizational culture, work structures, and the relationships between employees and employers.

A notable aspect of digitalization is the use of artificial intelligence (AI) and machine learning, which are progressively permeating all dimensions of HRM. These technologies enable the automation of routine tasks, accelerate decision-making, and generate personalized recommendations for employees. (Tambe, Cappelli & Yakubovich, 2019) AI thus becomes not only an optimization tool but also a means of fostering new forms of interaction between employees and the organization. At the same time, it raises critical ethical questions related to transparency, fairness, and the trustworthiness of algorithmic decisions. (Bogen & Rieke, 2018) This indicates that technological development is inseparable from trust, and responsible algorithm design becomes a prerequisite for the sustainable application of AI in HRM. Building on this foundation, the development of people analytics naturally follows. People analytics represents the systematic use of data to better understand processes related to employee performance, engagement, and development. (Angrave et al., 2016) It enables the integration of technological innovations with strategic decision-making by transforming large volumes of data into actionable insights that support long-term planning. While AI provides speed and automation, people analytics delivers the necessary context, validity, and strategic depth. (Aguinis, 2019) The potential of HR transformation lies in the synergy of these approaches: AI allows for scenario prediction and simulation, whereas analytics ensures that decisions are evidence-based and aligned with the real needs of the organization. This development inevitably affects performance management systems, which are evolving from traditional annual evaluations toward continuous and dynamic performance management. This approach relies on ongoing feedback, adaptive goals, and a focus on coaching. (DeNisi & Murphy, 2017; Aguinis, 2019) It creates an environment in which evaluation is not a one-off administrative task but an integral part of daily work. Integration with data analytics and AI further strengthens this process by enabling real-time monitoring of performance development and rapid response to deviations or emerging needs. Performance evaluation thus becomes a tool for continuous development directly linked to organizational effectiveness. In the context of performance, employee development and learning gain increasing importance. Modern learning platforms, including e-learning and adaptive learning systems, allow for personalized learning trajectories that enhance the transfer of knowledge into practice. (Shahzad et al., 2021) The development process is closely linked with onboarding, which is transforming into a systematic, data-supported process for integrating employees into the organizational environment. (Bauer et al., 2007; Klein et al., 2015) Learning therefore becomes continuous and directly connected to performance evaluation—the more effectively this cycle is managed, the higher the likelihood of employee engagement and loyalty. Another critical dimension of HR transformation is diversity and inclusion, which constitute one of the central pillars of modern people management. Diverse teams offer a broader spectrum of perspectives and are capable of generating higher-quality solutions; however, these benefits are realized only in an environment of psychological safety. (Nishii 2013 In: Sojka & Svetozarovová 2016) Inclusion complements technological and analytical innovations by ensuring equitable access for employees and fostering a culture of trust. In a digital environment, inclusion also translates into fair algorithm design, data process transparency, and equal opportunities, making it a necessary condition for the ethical implementation of digital HRM. These aspects logically lead to talent management, which is gradually transforming from an exclusive model focused solely on identifying high-potential employees toward a systemic approach that considers critical roles and key competencies. (Collings et al., 2019) This shift enables more effective management of internal labor markets, supports

organizational flexibility, and increases employee retention. (Cappelli & Keller, 2017) Talent management therefore becomes a natural continuation of preceding processes, it is integrated with performance evaluation, learning, analytics, and inclusion, creating a cohesive framework for building organizational competitiveness.

2. Methods

In this article, we outline the findings from the CIPD´s survey of 1,174 UK-based HR bosses to shed light on HR´s operating model from a technology and data perspective. The article is based on a secondary data analysis. Respondents were from organisations with 50 or more employees worldwide – the size we'd expect technology like HR information systems (HRIS) to become crucial for keeping track of employee records. This CIPD´s survey was selected for several reasons:

1. Relevance and credibility – CIPD (Chartered Institute of Personnel and Development) is one of the most recognized institutions in the HR field, and its surveys are widely cited in both academic and professional communities.
2. Representativeness – the inclusion of organizations of different sizes and industries allows for a nuanced analysis of HR practices and technology adoption.
3. Focus on digitalization – the survey specifically addresses the use of HR software, information systems, recruitment tools, and workforce planning platforms, which directly reflects the ongoing digital transformation of HRM.

3. Results

The results of a survey conducted by the Chartered Institute of Personnel and Development (CIPD) among 1,174 HR leaders in the United Kingdom provide a detailed insight into the structure and technological support of HR activities in organizations with more than 50 employees. Under these conditions, the use of Human Resource Information Systems (HRIS) has become a necessary prerequisite for effective human resource management. The data indicate that HR departments most frequently oversee recruitment (84.2%) and HR system administration (81.9%). Other key activities include diversity and inclusion, compensation and benefits, employee development and learning, performance management, and onboarding. (CIPD, 2023) Conversely, areas such as workforce planning (46.2%) or employer branding (22.8%) remain largely outside the direct scope of HR (Figure 1).

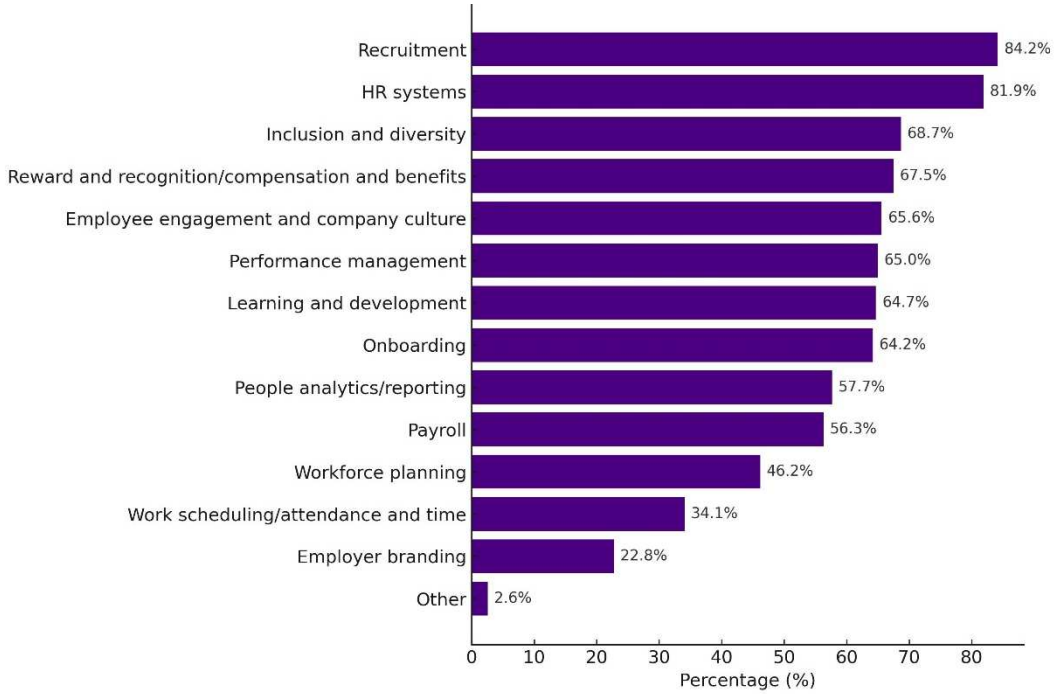

Figure 1. Activities the HR departments oversee in organisations
Source: Chartered Institute of Personnel and Development (2025)

In the context of digitalization and the use of HR software solutions (Figure 2), it is evident that the most widely adopted systems are HRIS (84.5%) and payroll software (82.9%). Fewer organizations make use of reward and recognition software (38.8%) or workforce planning tools (37.1%). This trend supports the theoretical framework emphasizing the importance of data-driven HR tools for strategic decision-making—particularly in workforce planning, where insufficient data collection (e.g., on skills gaps or talent availability in the labor market) can reduce the effectiveness of decision-making processes. (CIPD, 2023)

Figure 2. HR software or platforms used in your organisation
Source: Chartered Institute of Personnel and Development (2025)

An interesting finding is that although recruitment is among the most frequently managed HR activities, only 67% of HR managers reported the use of recruitment software. This discrepancy points to a potentially underutilized capacity of technological tools and suggests that the effective digitalization of HR processes has not yet been fully implemented across all organizations, which aligns with the theory of HRM digital transformation. (Marler & Parry, 2016) These findings correspond with the theory of Strategic Human Resource Management (SHRM), which emphasizes the importance of key processes related to the acquisition, development, and retention of talent as the main source of competitive advantage (Armstrong, 2020). The dominance of activities focused on recruitment and development also reflects the global trend toward so-called skills-based organizations, where skills represent the main criterion for workforce allocation and development. (World Economic Forum, 2023)

The results of the CIPD´s study confirm the existence of a causal relationship between technologies and the effectiveness of HR practices and processes. Larger organizations more frequently implement HRIS and payroll systems (82.9%), enabling them to collect comprehensive employee data and use it more effectively in decision-making. In contrast, weak data collection—particularly in the areas of skills and future workforce needs—limits the ability of organizations to engage in strategic workforce planning. CIPD highlights that as many as 46% of HR professionals do not collect any data on skills gaps or future labor market requirements. (CIPD, 2023) Similar conclusions are presented by Marler & Parry (2016), who stress that digitalization of HR processes alone does not guarantee higher efficiency. The decisive factor lies in the extent to which collected data are transformed into analytical outputs that support managerial decision-making. McKinsey (2021) further confirms that systematic people analytics contribute to reducing turnover, improving recruitment quality, and increasing employee productivity.

Another noteworthy aspect is the misalignment between the strategic importance of certain HR activities and the degree of technological support provided. While recruitment is the most frequently reported HR activity, only 67% of respondents confirmed the use of recruitment software or ATS. This technological deficit may lead to inefficiencies, as the absence of a digitalized system hampers the monitoring of recruitment metrics, reduces process transparency, and limits opportunities for optimization. (Parry & Strohmeier, 2014) A similar trend is observed in reward and recognition systems, where only 38.8% of respondents reported using dedicated software, despite its strategic importance for talent retention.

The CIPD findings should also be interpreted in the broader context of global HRM trends:

1. Digital transformation and AI in HR. Generative artificial intelligence is fundamentally reshaping recruitment, learning, and employee services. McCartney (2024) estimates that within five years, AI will impact more than one-third of the workforce.
2. Skills-based approach to talent management. The World Economic Forum (2023) highlights that by 2027 more than 40% of workers' skills will undergo significant change. Organizations that fail to implement systematic skills mapping through HRIS and analytics platforms risk mismatches between labor supply and demand, as well as increased talent shortages.
3. Reskilling and learning and developement as strategic priorities. Deloitte (2024) points to a shift from one-off training to continuous skills development, increasing the demand for integration of Learning management systems into HRIS. This trend supports the concept of learning in the flow of work, which enables employees to continuously upskill directly within their work processes.

4. Discussion

The results of the analysis highlight a clear transformation of the roles of HR departments within organizations. As illustrated by the first graph, the dominant activity of HR units remains recruitment (84.2%), followed by the implementation of HR systems (81.9%). This finding corresponds with trends that emphasize the digitalization and technologization of human resources. (Bondarouk & Brewster, 2016) Recruitment, as a key HR activity, also exerts a causal influence on the long-term performance of organizations, since the quality of newly hired employees determines the success of subsequent development, adaptation, and talent retention. The strong position of inclusion and diversity (68.7%) indicates a global shift toward value-driven HRM, which extends beyond purely administrative functions and aims to support organizational culture and social responsibility. Another significant category compensation and benefits (67.5%) points to the close relationship between a fair reward system and employee engagement. As highlighted in the literature, appropriately designed compensation schemes significantly influence not only retention but also employee satisfaction. (Kuvaas et al., 2017) An interesting finding is that employer branding appears in only 22.8% of organizations. This may indicate that while firms place emphasis on recruitment, they devote less attention to the long-term development of an attractive employer image. Such a misalignment may pose a strategic risk, particularly in the context of the global talent shortage and the phenomenon of the war for talent. (Collings et al., 2019)

The CIPD study demonstrated a strong technological dimension of HRM. The most widely used tools are HR information systems (84.5%) and payroll software (82.9%), confirming that the digitalization of administrative processes has become the standard. The high percentage of organizations using learning and development platforms (70.0%) reflects the trend of continuous learning (lifelong learning), which is a key response to the dynamic changes in the labor market. However, tools such as people analytics/reporting (55.0%) and performance management systems (53.2%) are used less frequently, pointing to gaps in the strategic use of data. Yet, the literature clearly emphasizes that HR analytics can deliver direct added value for decision-making and increase organizational effectiveness. (Angrave et al., 2016) Based on these results, it can be concluded that HR departments operate between two poles: on the one hand, they fulfill traditional administrative tasks (recruitment, HRIS, payroll), while on the other, they face increasing pressure for strategic transformation through data analytics, digital platforms, and skills-based approaches. The causal chains identified in the data underscore the need for systematic digitalization and the implementation of analytical tools.

From the perspective of HRM theory, these findings support the argument that HR has the potential to shift from an administrative center to a fully-fledged strategic partner. However, this shift is conditional upon technological readiness, data quality, and the ability to leverage analytics in decision-making. (Ulrich et al., 2008) Overall, the CIPD survey (2023) highlights that HR departments today combine traditional administrative functions with new, strategic tasks, with the effective use of HR

technologies becoming a key factor in supporting data-driven decision-making and strategic human resource management.

Conclusion

Based on the above, it can be synthesized that HRM transformation affects organizational performance through multiple interconnected channels. HR departments currently combine traditional personnel processes with digital solutions, with particular emphasis on recruitment, administrative HR systems, and compensation. Global trends such as diversity, inclusion, and employee development are gaining increasing importance; however, a disproportionality exists between the intensity of recruitment and the systematic development of employer branding. In the field of HR digitalization, it is evident that organizations concentrate primarily on the basic digitalization of processes, while advanced analytical tools and performance management platforms remain insufficiently widespread. This may represent a barrier to achieving a higher strategic level of HRM, which is conditional on the ability to work with data and link HR decisions to business outcomes. From a managerial practice perspective, it is therefore crucial to strengthen the use of HR analytics and to integrate digital tools not only into administrative but also into strategic HRM processes. At the same time, organizations should intensify efforts to develop employer branding and proactively build an inclusive organizational culture, which constitutes a significant determinant of employee engagement and loyalty.

Abstract

Research background: Employee engagement is a key factor that influences employee performance, satisfaction and the overall functioning of healthcare facilities. This article contributes to a better understanding of how the work environment influences healthcare employee engagement.
Purpose of the article: The aim is to identify and analyze the work environment factors that influence health worker engagement.
Methods: The theoretical analysis presents a review of secondary data obtained from relevant articles and studies published in indexed databases in recent years.
Findings & Value added: The aim of this article is to summarize the literature on work environment factors in relation to health worker engagement and thereby contribute to the scientific debate on this issue.

Keywords: Work engagement, Work environment factors, Healthcare worker engagement, Nurses work engagement, Model JD-R

JEL classification: I18, J28, J81, M12

1. Introduction

The work environment has a significant impact on how employees feel about their work. If conditions are favourable, employees feel motivated, satisfied and willing to engage in their tasks. On the opposite, if the environment is unfavourable, employees may feel frustrated, exhausted and employee engagement is lower. In the healthcare sector, this is an important connection. Healthcare worker engagement is an important factor in the delivery of quality healthcare to patients and is influenced by many factors related to the work environment, such as workload, management style, physical conditions in the workplace, etc. The aim of this paper is to theoretically clarify and understand which conditions help employees to feel good at work and to give their full attention to it, based on a study of the literature.

In today's work environment, which is characterized by rapidly evolving professional demands and ever-changing organizational dynamics, work engagement has become a fundamental pillar of organizational health and individual well-being. Work overload, high work demands, long working hours and pressure can all lead to healthcare workers feeling overwhelmed and this can cause them problems not only physically but also mentally. They are also exposed to significant work challenges that can negatively affect their engagement in the long term (Ni, et al., 2024; Debets, M. et al., 2022). Huang et al. (2021) describe the work environment as the combination of factors that influence the work environment, such as job satisfaction, performance, involves, and intrinsic and extrinsic factors that make up the work environment.

Madden, Mathias, and Madden (2015) identify factors that positively influence the work environment and may reduce turnover intention and increase work engagement among nurses. These factors include autonomy, environmental control, physician-nurse relationship, and organizational support. There is a strong relationship between work environment characteristics and work engagement. Authors Li, Li, and Wan (2019) state that the work environment is a factor that can be used to determine an employee's level of engagement with the organization. Highly engaged nurses are energetic,

[*] Corresponding author: sona.kucharova@smail.unipo.sk

enthusiastic about their work, which contributes to better job performance, achievement of work goals, and improved work-related outcomes.

1.1 Work engagement

In 1990, Willaim A. Kahn first introduced the concept of engagement and defined the concept of work engagement as using the members of an organization to play an active role in their work. He also stated that work engagement can affect personal growth and development at an individual level and equally have an impact at an organisational level (Muthmainnah et al., 2023).

Schaufeli et al. (2002) characterize work engagement as a work-related state of mind and is characterized by vigor, dedication, and commitment. Vigour is characterised by enthusiasm and perseverance in the performance of work tasks. Dedication is associated with engagement and a sense of importance that the employees attribute to their work. Absorption refers to the degree to which a person is immersed in his or her work (Sohrabizadeh and Sayfouri, 2014). They also mention burnout in the context of engagement, which is defined as a work-related syndrome and is manifested by exhaustion, cynicism, and ineffectiveness (Schaufeli et al., 2002). According to Bakker et al. (2011) work engagement reflects how employees perceive their job role and their work. High levels of work engagement are associated with doing better work due to experiencing positive emotions more often, as they motivate work performance. As well as this, engagement improves health and psychological wellbeing as a result of which employees are able to devote more energy to their work, further leading to valuing feedback and this has a positive effect on their future performance. At the same time, highly engaged employees are an asset to their colleagues because they are able to transfer their enthusiasm to them, thus increasing the effectiveness of the entire team (Bakker and Demerouti, 2008). Research has shown that work engagement acts as a mediator of the relationship between work environment and intention to change jobs (Szilvassy and Sirok, 2022). In a healthcare environment characterized by increasing work demands and limited resources, it is essential to provide a work environment that generates positive work attitudes and behaviours (Gupta et al., 2016).

Banerjee (2015) describes several important reasons why an engaged workforce is essential in 21st century healthcare. The first is the increased need for health services due to an ageing population, secondly it is the increased demand for health workers, and thirdly it is the ageing of the health workforce. The factors which are ageing population, urbanization and lifestyle have increased the number of people living with chronic diseases, this in turn will lead to a high demand for various health care services and will cause a shortage of health care workers. López-Cabaracos et al. (2020) point to the importance of an engaged health workforce specifically during the COVID-19 pandemic and as an example, they report that nurses with high levels of engagement experienced less burnout when faced with high work demands during the COVID-19 pandemic. When we talk about work engagement in healthcare, there are a number of factors related to it, these can be managed by organisations to improve the level of work engagement of their employees. Authors Van Bogaert et al. (2014) identify a number of reasons that affect nurses' work engagement, including: complexity of work, role ambiguity, high responsibility, psychological and physical workload, lack of job control, extent of control and workload, lack of opportunities for intellectual and professional growth, lack of leadership, lack of social support from supervisor and/or peers, challenging nurse-doctor collaboration, and imbalance between effort and reward.

1.2 Job Demands-Resources (JD-R)- model of work engagement

Schaufeli (2017) describes in more detail the JD-R model, which was introduced about fifteen years ago to understand burnout syndrome, a chronic work-related condition of psychological distress that is characterized by exhaustion and emotional exhaustion, mental distancing (i.e., cynicism and lack of enthusiasm), and diminished personal performance, which includes doubts about one's competence and contributions at work. After a few years, the model was expanded to include work engagement, the meaning of which we described in the previous subsection. This model determines how 2 specific sets of conditions can development employee welfare – these are job resources and job demand, which every job includes.

Job demand require physical and mental effort and all that comes with psychological and physiological costs (Lee, Shin, and Baek, 2017). Job demands represent the things at work that drain energy, such as work overload, conflicts with other people, and uncertainty of future employment. The

dimensions of job demands are divided into 7 dimensions: pace and quantity of work, psychological strain, emotional strain, physical effort, task changes, job ambiguity and future uncertainty. Job resources are aspects of work that help achieve work goals, that can reduce job demands, and that can enhance learning. Job resources are divided into seven dimensions: information, communication, participation, relationships with colleagues, relationships with supervisors, rewards, and autonomy at work (Lee, Shin, and Baek, 2017; Schaufeli, 2017).

The JD-R model is a validated model that specifies the relationships between both job and personal characteristics, leadership, employee satisfaction and performance. This model tells us that reducing work demands, increasing both work and personal resources, and stimulating engaged leadership prevents burnout and increases work engagement. If burnout is prevented and work engagement increases there are fewer negative and more positive outcomes for both employees and the organization (Schaufeli, 2017).

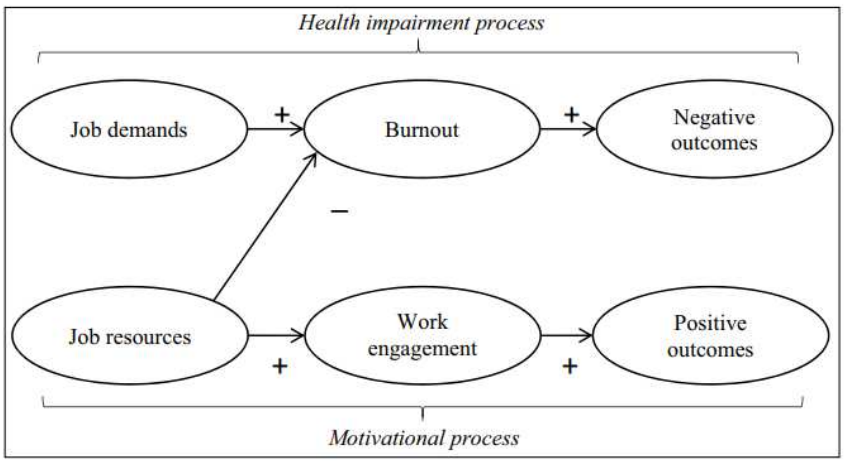

Figure 1. The Job Demands Resources Model
Source: Schaufeli (2017)

The JD-R model predicts 2 processes: a health impairment process and a motivational process. As we can see in Figure 1, high workload increases the risk of burnout and this leads to negative consequences (e.g., health problems, increased turnover) and on the other hand, work resources encourage work engagement and act as a motivator. Further in the model we can see that the absence of work resources also leads to burnout. Job resources can mitigate the impact of job demands on burnout (Bakker and Demerouti, 2017). Over the years, there have been several modifications to the model; however, the basic assumptions of the model have remained unchanged: job demands predict burnout, job resources predict job commitment, and job resources also have an impact on burnout (Lesener, Gusy and Wolter, 2019).

2. Methods

The paper has the form of a theoretical analysis aimed at a deeper understanding of the issue studied, which serves as a basis for further research. It provides a literature review and identifies key concepts and theoretical foundations of the issues of work environment factors and work engagement in the health sector, complemented by a review of research findings in this area. The literature was selected based on its relevance to the main topics of the working environment and work engagement in healthcare. We conducted a literature review, selecting peer-reviewed articles published in recent years that focused on studies relevant to the work environment and work engagement of healthcare workers. They were searched in academic databases such as PubMed, Scopus, and Web of Science.

The main objective of this paper is to examine how various factors in the work environment influence the level of work engagement among healthcare workers. In order to support the main objective, the article also focuses on the following sub-objectives:

- to identify which factors in the work environment have the greatest impact on work engagement,
- to examine differences in engagement by profession,
- to examine how different personal and organizational factors influence work engagement.

The resulting synthesis provides a comprehensive overview of the most important factors influencing the work engagement of healthcare workers. The factors analyzed include workload, emotional exhaustion, leadership, fairness, communication, working conditions, and psychosocial stressors, which are often mentioned in studies as key to the work engagement of healthcare workers.

3. Results

This theoretical analysis summarizes existing knowledge about the impact of the work environment on the engagement of healthcare workers. The following two subchapters present specific research findings - factors that influence engagement and the broader impact of the work environment on employees.

3.1 Factors influencing the work engagement of healthcare workers

Moreno-Matínez and Sánchez-Martínez (2024) conducted a survey through a questionnaire in which 321 professionals participated, 60.7% of whom were health professionals and 39.3% of whom were healthcare workers from the Central Catalonia region. They investigated what most influences health workers' engagement and how the work environment affects it. It was found that higher workload can be associated with higher work engagement - especially if health workers perceive their work as meaningful. On the other hand, emotional exhaustion has a negative impact on engagement. Job satisfaction was higher for those workers who had better pay conditions and more stable working arrangements. Another interesting finding was that doctors were more overworked than nurses and in general women showed higher levels of engagement but also emotional exhaustion. Factors such as irregular shifts and unpaid overtime contribute to decreased job satisfaction and work engagement.

Ge et al. (2021) in 2018 analysed the data of 1327 participants from The Chinese Sixth National Health and Services Survey in Sichuan Province. They found that the work environment plays a big role if workers are under pressure, work overtime, face stress, unpleasant relationships, and have no opportunity for career growth, their job well-being decreases. Further, their research has shown that workers who feel they put in a lot of effort at work but are not adequately rewarded financially or in the form of recognition feel less satisfied, are less engaged, and there is also an emphasis on perceived deterioration in health. If they are satisfied, motivated and engaged, they tend to rate their health better.

Sohrabizadeh and Sayfouri (2014) found that factors such as reward, management support, autonomy and feedback, opportunities for growth, and other positive job characteristics increase nurses' engagement. This exploratory study was conducted in 2 Iranian hospitals and 279 nurses participated.

A study by Shanafelt et al. (2019) showed that physicians in the U.S. have higher rates of burnout and lower satisfaction with work-life balance compared to other workers. This may significantly affect their motivation and work engagement.

An interesting perspective on the relation between work environment and nurses' work outcomes is provided by the research of Dutra, Cimiotti and Guirardello (2018), which was carried out in three hospitals in Brazil on a sample of 450 nurses working in 48 wards. Although this research focuses on burnout and intention to leave the job, these factors lead to reduced worker engagement. The aim was to investigate what aspects of the work environment influence job satisfaction, levels of burnout and nurses' intention to leave their jobs. Results showed that up to 26% of nurses reported high levels of emotional exhaustion, 28% were dissatisfied with their jobs, and 12% said they planned to quit within 12 months. The authors also identified key factors that negatively influenced job dissatisfaction - these were lack of control over the work environment and high levels of emotional exhaustion. Lack of staffing, emotional exhaustion and job dissatisfaction were related to the decision to leave employment. The quality of the work environment is a significant indicator of work engagement, job satisfaction and retention.

3.2 The impact of the work environment on work engagement

Debets et al. (2022) conducted a survey involving 385 doctors from academic and non-academic hospitals in the Netherlands. According to the research, work environment factors such as opportunities for professional development, participation in decision-making and good interpersonal relationships positively influence employee engagement. The factors mentioned above increase employees' motivation and engagement at work, resulting in better outcomes. High workload, lack of support, lack of development opportunities can reduce employee engagement and lead to burnout. These factors can reduce work capability and impair workers' well-being.

Hegazy et al. (2022) focused on examining the relationship between nurses' perceptions of the work environment in Egypt and their work engagement. The research was conducted on a sample of 400 nurses. The results showed that the majority of nurses (66.2%) perceived their work environment negatively. The factors that contributed most to this negative evaluation are:

- lack of support from supervisors,
- low level of participation in decision making,
- poor communication,
- high workload.

At the same time, more than half (55.5%) showed a low level of engagement. This research also showed a strong positive relationship between how nurses perceived their work environment and their work engagement.

The 630 primary care staff at the Ljubljana Community Health Centre (e.g. nurses, health assistants) showed a high level of engagement. Factors that supported this engagement were: good relationships with colleagues and supervisors, communication in the workplace, leadership style, space for professional development, and availability of resources needed for work. It was also confirmed in this research that soft factors of the work environment (e.g., appreciation, communication) can have a large impact on engagement as well as on the quality of care provided. This survey also looked at managers who were found to be less engaged, which they described as a surprising finding (Szilvassy and Sirok, 2022).

Kim, Lee and Lee (2023) found what work environment factors influence nurses' engagement in South Korea. They analyzed data from the 5th Korea Working Conditions Survey, which included 477 nurses. The aim was to identify how various factors such as leadership, work and personal resources affect nurses' engagement at work. The research shows that the most important factor is the quality of leadership - nurses showed higher engagement if they felt supported, acknowledged and treated fairly by managers. Further, perceiving their work as meaningful is important. Organisational justice is also an important factor, i.e. ensuring fair conditions (e.g. fair pay) and support from colleagues, which contributes to better teamwork. The factor representing involvement in decision-making was not a significant predictor of engagement. This article has shown that creating a positive, fair and supportive work environment is key to maintaining an engaged and motivated health workforce.

Since in the previous subsection we discussed the theoretical perspective on the JD-R model, we present research based on this model of job demands and job resources. Muthmainnah et al. (2023) in their study examined the relationship between job demands, job resources, job commitment and organizational commitment of nurses in a hospital setting. This model suggests that work engagement arises when work resources are sufficient to cope with work demands. The aim was to identify the factors that influence nurses' work engagement and how this influences their engagement with the hospital in which they work. The research showed that when there are positive work resources such as support from supervisors and peers, clear work assignments, and opportunities for professional development, they increase nurses' work engagement. Conversely, high workloads, lack of staff - which are part of the job demands - can lead to reduced engagement and even burnout. Further, it has been found that when nurses are more engaged, they are more loyal to the organization they work for and want to stay there, which also leads to lower turnover.These findings underscore the importance of creating a work environment that fosters nurse engagement. The research sample consisted of up to 200 nurses at Stella Maris Hospital in Makassar in Indonesia.

Healthcare workers face a variety of psychosocial stressors such as (Weyers et al., 2006):

- long working hours,
- night shift work,
- demands associated with patient care,
- medical disputes,
- workplace violence,
- emotional stress associated with poor interactions with patients and colleagues, and
- last but not least, they are plagued by poor career prospects.

4. Discussion

The findings of this theoretical analysis point to several key factors that influence the work engagement of healthcare workers, such as support from management, good workplace relationships, opportunities for growth, meaningful work, manageable workload, and fair conditions.

Positive factors include, for example, support from superiors, good interpersonal relationships, opportunities for professional growth, and fair working conditions (Debets et al., 2022; Kim, Lee, and Lee, 2023; Sohrabizadeh and Sayfouri, 2014). Healthcare workers who feel that their work is meaningful are more engaged, even when faced with a higher workload (Moreno-Matínez and Sánchez-Martínez, 2024).

Negative factors such as high workload, staff shortages, poor communication, and low involvement in decision-making contribute to reduced engagement, burnout, and dissatisfaction (Hegazy et al., 2022; Dutra, Cimiotti, and Guirardello, 2018; Shanafelt et al., 2019).

Some studies also point to differences between professions and genders. Differences between professions are confirmed, for example, by a study by Moreno-Matínez and Sánchez-Martínez (2024), which showed that doctors were more overworked than nurses and that women demonstrated higher work engagement but also higher emotional exhaustion. Similar findings were presented by Szilvassy and Sirok (2022), where managers were less engaged than other workers. Some studies point out that nurses felt a stronger need for support and communication (Kim, Lee and Lee, 2023; Hegazy et al., 2022; Sohrabizadeh and Sayfouri, 2014).

The job demands and resources (JD-R) model also provides an important perspective, stating that engagement increases when employees have sufficient resources, support, and conditions to cope with demanding work tasks. This is confirmed by research by Muthmainnah et al. (2023), which shows that positive job resources, such as support from superiors, clear tasks, and opportunities for development, increase nurses' engagement. In contrast, a lack of these resources leads to exhaustion and reduced engagement.

This means that the specific needs of different groups should be taken into account when improving the work environment.

The absence of empirical data represents a certain limitation. The results are based on studies with different methodological approaches, differing in context, sample, and geographical area. Not all professions or countries were equally represented in the analyzed studies, so the results cannot be fully generalized.

The results clearly show that a high-quality work environment influences the motivation, satisfaction, and retention of healthcare workers. Although this was a theoretical analysis, the results provide valuable insight and a basis for future research.

Conclusion

Several studies show that factors such as: support from management, good relationships among colleagues, meaning at work, opportunity for professional growth and adequate workload have the greatest impact on healthcare worker engagement. If employees feel supported at work, their efforts are valued and their opinions are heard they are more motivated and willing to stay in the job for the long term. These insights can help healthcare leaders to create better working conditions for employees.

Future research could focus on a deeper examination of work environment factors and which specific ones have the most significant impact on engagement, and on evaluating the effectiveness of specific practices that can improve the work environment.

Abstract

Research background: This article addresses a crucial need to understand employee engagement within the Slovak healthcare system, given the sector's inherent challenges. It theoretically explores engagement's foundational principles, encompassing dimensions like organizational commitment and job satisfaction, and posits its critical role in fostering a high-performing and sustainable healthcare environment.
Purpose of the article: The primary objective of this paper is to highlight the critical role of engagement in fostering a high-performing and sustainable healthcare environment. By exploring the influence of factors like leadership, organizational culture, recognition, and professional development, this paper seeks to establish a conceptual understanding of how these elements can shape engagement levels within the Slovak context.
Methods: The research synthesizes existing academic concepts to establish a new conceptual model for employee engagement. This approach involves systematically analyzing foundational principles, dimensions, and potential influencing factors of engagement to apply them within the specific context of the Slovak healthcare system.
Findings & Value added: The article theorizes on the potential benefits of high employee engagement, including enhanced patient outcomes, reduced staff turnover, and increased innovation. It also concurrently theorizes on the unique challenges faced in cultivating such an environment within Slovakia's specific socio-economic and structural landscape. Employing a theoretical exploration method, the research systematically examines foundational principles to create a solid conceptual basis. The core value of this work is to systematically ground the issue of employee engagement within Slovak healthcare, offering a vital starting point for empirical studies and the formulation of hypotheses relevant to this national context.

Keywords: Employee engagement, Healthcare, Slovak healthcare

JEL classification: J53, M54

1. Introduction

Employee engagement stands as a cornerstone of organizational efficacy, wielding substantial influence over productivity, innovation, and employee retention (Lušňáková, 2022). Within the demanding and dynamic landscape of Slovak healthcare, the imperative of fostering heightened employee engagement is amplified due to the sector's direct impact on patient care and public health outcomes (Bharath & Sreedevi, 2020). Healthcare organizations that cultivate environments where employees are deeply connected to their work and committed to the organization's mission are more likely to exhibit continuous growth, demonstrating high levels of energy and a significant capacity for success (Halm, 2011). Slovak healthcare, characterized by its unique structure, funding mechanisms, and regulatory framework, presents specific challenges and opportunities for nurturing employee engagement. Recognizing and addressing these factors is critical for optimizing the performance of healthcare professionals and ensuring the delivery of high-quality, patient-centered care within the Slovak Republic.

[*] Corresponding author: denis.tirpak@unipo.sk

The complex interplay between organizational culture, employee well-being, and streamlined operational processes is fundamental to ensuring the long-term viability and excellence of healthcare services. This study seeks to provide a comprehensive exploration of employee engagement within Slovak healthcare, beginning with an examination of the current state, subsequently identifying critical challenges that hinder engagement, and culminating in the proposition of targeted strategies designed to cultivate a more motivated, connected, and productive healthcare workforce.

Several interconnected factors shape the landscape of employee engagement within Slovak healthcare. Workload and work-life balance exert a powerful influence, with the demanding nature of healthcare professions frequently leading to burnout and diminished engagement. Perceptions of fairness, encompassing equitable compensation, recognition, and opportunities for advancement, significantly impact how employees perceive their value within the organization (Hoxha et al., 2024). The availability of resources and support systems, including access to modern equipment, training programs, and supportive leadership, plays a vital role in enabling employees to perform their duties effectively and feel empowered in their roles. Organizational culture, defined by the prevailing values, norms, and leadership styles, profoundly affects employee morale and engagement. The sustained success and competitive edge of any healthcare organization are fundamentally dependent on its ability to attract, develop, and retain a highly skilled and engaged workforce, with strategic investment in human capital proving essential (Owusu & Gregar, 2021). Cultivating a healthcare environment where leaders prioritize and demonstrate support, compassion, respect, and appreciation for their staff is not merely beneficial but essential for achieving excellence in healthcare service delivery (West, 2013). Job satisfaction is not solely determined by isolated factors but emerges from a complex interplay of personal characteristics, managerial practices, and the overall work environment (Hoxha et al., 2024).

2. Literature review

Extensive research underscores the link between employee engagement and various positive outcomes in healthcare, including improved patient satisfaction, reduced medical errors, and enhanced organizational performance (Biddison et al., 2015). Engaged healthcare professionals demonstrate a greater commitment to their roles, exhibit heightened levels of energy and enthusiasm, and foster a deeper connection to their employers, ultimately translating into superior patient care and positive healthcare results (Armstrong et al., 2021). When employees are deeply connected to their work and the organization's mission, they are more likely to contribute innovative ideas, collaborate effectively with colleagues, and demonstrate resilience in the face of challenges. Conversely, disengaged employees may experience decreased productivity, increased absenteeism, and a higher likelihood of turnover, all of which can negatively impact the quality and efficiency of healthcare services. A positive, optimistic, and supportive workplace atmosphere, coupled with strong leadership trust, significantly elevates staff engagement, highlighting the importance of a nurturing organizational culture. Furthermore, studies indicate a clear correlation between staff well-being, patient safety, and the overall quality of care, reinforcing the necessity of prioritizing employee wellness within healthcare settings (Pavithra et al., 2022). Creating well-defined teams with clear objectives, interdependent working relationships, and regular performance reviews is critical for fostering teamwork, which is fundamental to delivering high-quality healthcare (West, 2013). It is ubiquitously recognized that healthcare professionals operate within inherently stressful environments, stemming from the gravity of their responsibilities, the emotional intensity of patient interactions, and the ever-present demands for precision and efficiency (Gümüş et al., 2021).

The analysis of Slovak literature on employee engagement in healthcare reveals a complex interplay between motivational factors, organizational culture, leadership, and remuneration. Engagement is not merely about job satisfaction; it encompasses the willingness of healthcare professionals to go beyond their formal duties, directly influencing the quality of patient care and organizational performance.

Across the reviewed studies, authors such as Jankelová, Psota, and Mucska (2019), Pažitný a Zajac (2021), Pažitný (2020), Szalay (2019) consistently highlight that engagement is shaped by both intrinsic and extrinsic factors. Intrinsic drivers include professional growth opportunities, recognition, and a sense of purpose, while extrinsic drivers involve adequate pay, supportive leadership, and a positive work environment.

However, the current state of engagement in Slovak healthcare is hindered by persistent barriers. Low remuneration, excessive administrative workload, limited career advancement, and hierarchical

management structures are repeatedly identified as key obstacles. These challenges not only reduce motivation but also contribute to staff turnover and the migration of healthcare workers abroad.

The literature also points to the pivotal role of leadership in fostering engagement. Leaders who communicate openly, involve staff in decision-making, and provide constructive feedback create conditions where engagement can thrive. Conversely, rigid and top-down management styles tend to suppress initiative and reduce commitment.

2.1 Strategies and Challenges to Employee Engagement in Slovak Healthcare

Specific challenges within the Slovak healthcare system may impede employee engagement. Limited resources and budgetary constraints can result in inadequate staffing levels, outdated equipment, and restricted access to professional development opportunities, all of which can contribute to employee frustration and disengagement. Bureaucratic processes and administrative burdens can further detract from employee satisfaction, diverting valuable time and energy away from direct patient care. Addressing these challenges requires a multi-faceted approach that encompasses systemic reforms, organizational interventions, and individual-level strategies. Systemic reforms may involve advocating for increased healthcare funding, streamlining administrative processes, and implementing policies that promote work-life balance for healthcare professionals (Karaferis et al., 2022).

Organizational interventions may focus on fostering a culture of open communication, providing opportunities for employee involvement in decision-making, and implementing recognition programs to acknowledge and reward employee contributions. Individual-level strategies may include providing stress management training, promoting self-care practices, and offering mentorship opportunities to support employee well-being and professional growth. The implementation of continuous feedback mechanisms and the development of targeted engagement and training programs are essential for integrating principles into the organizational culture, leading to tangible improvements in job satisfaction and healthcare quality (Hoxha et al., 2024). Exploring strategies for building a sustainable healthcare system necessitates a systems approach at every level (Al Shamry et al., 2024). This includes the integration of management strategies across domains such as resource allocation, quality control, workforce management, and technology implementation (Al Shamry et al., 2024). Healthcare organizations can foster settings that greatly enhance job satisfaction by mitigating workplace stress through optimized operations and waste reduction (Hoxha et al., 2024). A healthcare organization that cultivates a supportive environment, characterized by its attentiveness to the needs of its workforce and the provision of robust support systems, is statistically more likely to foster heightened job satisfaction, leading to increased career fulfillment and a stronger dedication to professional responsibilities.

By recognizing the achievements of healthcare workers, and supporting their performance, there will be improved job satisfaction and accepting the organizational change (Kim, 2021). Optimizing resource allocation through the strategic deployment of centralized procurement systems, integrated with real-time inventory management technologies, offers a concrete pathway to minimize waste generation and enhance operational efficiency, particularly within healthcare environments facing resource scarcity. Moreover, the implementation of quality improvement initiatives, such as Lean and Six Sigma methodologies, facilitates the reduction of errors and the streamlining of workflows, thereby enhancing both patient outcomes and operational cost-effectiveness. A robust and nurturing organizational culture serves as a critical buffer against the detrimental effects of demanding workloads, while simultaneously cultivating a profound sense of value, recognition, and belonging among healthcare professionals, thereby fostering enhanced engagement and commitment.

3. Methods and Conceptual Framework

The importance of sufficient staff in appropriate locations at the right times was made clear during the COVID-19 pandemic because of the unpredictable and high volume of patients (Yinusa & Faezipour, 2023). Workforce planning includes skill mix and appropriate staffing levels.

The systematic review will need to include staff from different disciplines and focus on hospital settings.

The purpose of this study is to explore the current state of employee engagement in Slovak healthcare, identify key challenges, and propose evidence-based strategies to foster a more engaged and motivated healthcare workforce. This research will utilize a mixed-methods approach, combining quantitative surveys to measure employee engagement levels with qualitative interviews to gain a deeper

understanding of the factors influencing engagement. The study population will consist of healthcare professionals working in various settings across Slovakia, including hospitals, clinics, and long-term care facilities. Quantitative data will be analyzed using statistical methods to identify significant correlations between employee engagement and various organizational and individual-level factors. Qualitative data will be analyzed using thematic analysis to identify recurring themes and patterns related to employee experiences and perspectives on engagement.

The expected outcomes of this study include a comprehensive assessment of employee engagement in Slovak healthcare, identification of key challenges and opportunities for improvement, and the development of practical recommendations for fostering a more engaged and motivated workforce. The study will also contribute to the broader body of knowledge on employee engagement in healthcare and provide valuable insights for policymakers, healthcare administrators, and other stakeholders seeking to improve the well-being and performance of healthcare professionals in Slovakia. Furthermore, the research findings aim to inform the development of targeted interventions and policies to address the specific needs and challenges faced by healthcare workers in Slovakia, ultimately contributing to improved patient care and a more sustainable healthcare system.

Addressing the multifaceted challenges within the healthcare sector necessitates a comprehensive approach. The development and implementation of training programs designed to enhance clinical skills are pivotal in equipping healthcare professionals with the requisite competencies to deliver superior patient care, while also fostering a culture of continuous professional development and lifelong learning. By investing in the professional growth of healthcare workers, organizations can enhance their capabilities and improve the quality of care provided.

In order to provide better well-being among Slovak nurses, further studies in different countries could be done to help (Gurková et al., 2011). Also to look at the demographic factors of each country in order to help with the shortage.

Based on the theoretical framework presented in the article, the following hypotheses are formulated for future empirical research:

H1: There is a significant positive relationship between the level of employee engagement and patient outcomes within Slovak healthcare institutions.

H2: There is a significant negative relationship between the level of employee engagement and employee turnover rates in Slovak healthcare institutions.

H3: Higher levels of employee engagement are positively associated with an increase in innovative practices and adoption of new technologies within Slovak healthcare institutions.

H4: The quality of leadership, as perceived by employees, is a significant predictor of employee engagement levels in Slovak healthcare.

H5: A positive organizational culture, characterized by trust, open communication, and shared values, mediates the relationship between leadership and employee engagement in Slovak healthcare institutions.

H6: The availability of professional development and recognition programs is positively correlated with higher levels of employee engagement among healthcare professionals in Slovakia.

Path to Empirical Validation

The theoretical exploration of employee engagement within the Slovak healthcare system provides a crucial conceptual foundation for a new and urgently needed research agenda. While our initial analysis identifies key relationships and potential benefits, these remain speculative until subjected to rigorous empirical testing. This discussion outlines how the formulated hypotheses can be addressed in future studies and explores the broader implications of their potential findings. It delves into the nuances of the Slovak context, arguing that any empirical investigation must be sensitive to the unique socio-economic and structural factors at play.

Validating the Engagement-Performance Link (H1, H2, H3)

The proposed relationship between employee engagement and key performance indicators—patient outcomes (H1), staff turnover (H2), and innovation (H3)—is the cornerstone of this research. The literature from other national contexts strongly supports these links. For example, studies in the United States and the United Kingdom have consistently shown that highly engaged nursing staff are associated with lower patient mortality rates, fewer medication errors, and higher patient satisfaction scores.

Similarly, the cost-benefit analysis of reducing staff turnover is a well-established economic argument for prioritizing engagement. The current theoretical model posits that these relationships are not only applicable but are critically important for the sustainability of the Slovak healthcare system, which grapples with both resource constraints and a talent drain.

Future research should seek to quantify these relationships. For instance, an empirical study could collect engagement data from a representative sample of hospitals and clinics across Slovakia using validated scales (e.g., the Utrecht Work Engagement Scale). This data could then be correlated with objective performance metrics. Patient outcomes could be measured using indicators like readmission rates, patient-reported experience measures, and adherence to quality protocols. Turnover could be tracked through human resources data, while innovation could be assessed via surveys on the adoption of new technologies, process improvements, or the implementation of new service models. Proving these links empirically would provide a powerful, evidence-based argument for policymakers and hospital administrators to invest in engagement-boosting initiatives.

Deconstructing the Antecedents of Engagement (H4, H5, H6)

Beyond simply measuring engagement's impact, a core purpose of this research is to understand its drivers. Hypotheses H4, H5, and H6 focus on the critical role of leadership, organizational culture, and professional development. In many Western European healthcare systems, transformational leadership—characterized by inspiring, motivating, and intellectually stimulating employees—has been identified as a key antecedent to high engagement. Our hypothesis (H4) suggests this holds true for Slovakia as well. However, the hierarchical and sometimes rigid management structures in Central and Eastern European public sectors could present a unique challenge to the widespread adoption of such leadership styles.

Furthermore, a supportive and positive organizational culture (H5) is not merely a "nice to have"; it is a vital mechanism that translates leadership behaviors into employee engagement. In a high-pressure environment like healthcare, where burnout is a constant threat, a culture of trust and psychological safety is paramount. An empirical study could use structural equation modeling to test whether a positive culture indeed mediates the relationship between leadership and engagement. This would not only validate the hypothesis but also provide a roadmap for interventions: it's not enough to train leaders; one must also actively cultivate the culture in which their behaviors can thrive.

Finally, the link between professional development and engagement (H6) is a critical one for a knowledge-based profession. Healthcare is constantly evolving, and a feeling of stagnation can quickly lead to disengagement. This is particularly relevant in the Slovak context, where access to continuous professional development might be unevenly distributed between urban and rural hospitals or across different specialties. Validating this hypothesis would underscore the need for strategic investment in training, skill-building, and career pathing as a key lever for improving engagement and, by extension, the quality of care.

The Unique Context of Slovak Healthcare

The theoretical grounding of this study in the Slovak context is what gives it its unique value, but also its primary challenge. The hypotheses must be tested with an acute awareness of the specific socio-economic and structural landscape. This includes:

- **Public vs. Private Sector Divide:** A significant portion of Slovak healthcare is state-funded, with a smaller but growing private sector. Engagement drivers and challenges might differ significantly between these two models due to variations in funding, management autonomy, and patient expectations.
- **Legacy Issues:** The healthcare system still carries some legacy structures from the socialist era, which may influence management styles, organizational culture, and perceptions of autonomy among staff.
- **Demographic Challenges:** Slovakia, like many Central European nations, faces an aging population and a "brain drain" of skilled medical professionals seeking higher wages and better working conditions abroad. Understanding how engagement can mitigate this talent flight is a crucial component of any future research.
- **Regulatory and Funding Environment:** The legal and financial framework of the Slovak healthcare system can limit institutional flexibility in rewarding employees, creating a potential barrier to engagement.

Future empirical research must account for these variables. A comparative study, for instance, could analyze data from both public and private institutions to see if the hypotheses hold equally true across both sectors. Similarly, demographic data and employee experience surveys could be used to explore how perceptions of leadership and culture vary across different generations of healthcare workers.

Implications and Future Research Avenues

The successful empirical validation of these hypotheses would have profound practical implications. It would provide policymakers and hospital administrators with concrete, actionable evidence to justify investment in human resource management strategies that prioritize employee well-being and engagement. This is not simply a matter of morale but of operational efficiency, patient safety, and long-term systemic sustainability.

Beyond the initial validation, future research could explore more nuanced questions, such as:

- The role of specific cultural factors within different regions of Slovakia in shaping engagement.
- The effectiveness of specific interventions (e.g., leadership training programs, flexible scheduling, peer recognition systems) on improving engagement metrics.
- The longitudinal impact of a highly engaged workforce on the financial health and reputation of healthcare institutions.

In conclusion, this theoretical paper has laid the groundwork for a robust and impactful research agenda. By transitioning from theoretical exploration to empirical validation, we can move from understanding *what* employee engagement is to providing concrete evidence for *why* it is indispensable for the future of Slovak healthcare. The hypotheses presented here are not just academic exercises; they are a call to action for a research community committed to improving the lives of both healthcare workers and the patients they serve.

4. Discussion

This article has established a conceptual foundation that bridges the theoretical understanding of employee engagement with its practical application within the Slovak healthcare system. While the current work is purely theoretical, it provides a critical roadmap for future empirical inquiry. The core of this discussion lies in articulating how the formulated hypotheses will guide researchers in validating the relationships proposed in our model and in uncovering the specific, nuanced dynamics at play in the Slovak context. It is essential to transition from a theoretical stance to an evidence-based one to provide actionable insights for policymakers and healthcare administrators.

The primary argument of our framework is that employee engagement is not merely a human resources metric but a fundamental driver of systemic performance and sustainability. The proposed links to improved patient outcomes (H1), reduced employee turnover (H2), and enhanced institutional innovation (H3) suggest that a disengaged workforce is a significant barrier to progress. Verifying these connections empirically would provide a powerful incentive for systemic change. Future research must, therefore, be designed to quantitatively measure engagement levels across various institutions and correlate them with objective data points on patient safety, staff retention, and the adoption of new medical technologies or operational efficiencies.

Furthermore, the article theorizes that engagement itself is shaped by a specific set of antecedent factors. The quality of leadership (H4) emerges as a central element, serving as a direct influence on how employees perceive their role and value within the organization. We also propose that a positive organizational culture (H5) acts as a crucial intermediary, translating effective leadership behaviors into tangible feelings of trust and commitment among staff. This highlights that simply mandating a new leadership style is insufficient; a supportive, open, and psychologically safe environment must be cultivated to maximize engagement. Finally, the role of professional development and recognition (H6) is identified as a key factor in preventing stagnation and fostering a sense of continuous growth and value among professionals. Empirical studies could use sophisticated statistical methods, such as mediation analysis, to confirm these causal pathways and provide a detailed understanding of how these factors work in concert.

The distinctiveness of this research lies in its focus on the Slovak context. Any future empirical study must acknowledge and control for the unique socio-economic and structural challenges identified in this paper, including the public versus private sector divide, the lasting impact of legacy organizational

structures, and the persistent issue of professional talent leaving the country. By taking these factors into account, empirical research will not only validate our theoretical model but also provide a tailored understanding that is relevant and applicable to the specific needs of Slovak healthcare.

Conclusion

In conclusion, the healthcare industry's pursuit of sustainability is intricately linked to the strategic integration of digital technologies within a supportive ecosystem, facilitating data-driven decision-making, optimizing resource allocation, and ultimately fostering a resilient, patient-centered healthcare paradigm (Fragão-Marques & Özben, 2022). Integrating sustainability principles into healthcare necessitates a comprehensive approach, encompassing resource efficiency, waste reduction, and workforce well-being (Woeber, 2013). Strategic workforce management, encompassing aspects such as recruitment, retention, training, and equitable compensation, constitutes a cornerstone of sustainable healthcare systems, ensuring a consistently skilled, engaged, and motivated workforce capable of meeting the evolving demands of patient care (Al Shamry et al., 2024).

This theoretical paper serves as a foundational step toward understanding the complex dynamics of employee engagement within the Slovak healthcare system. The conceptual model presented herein posits that engagement is not a standalone concept but rather a critical outcome influenced by several key factors. Our theoretical model posits that leadership behaviors, specifically those fostering motivation and trust, are central to cultivating an engaged workforce. A supportive organizational culture, which provides a psychologically safe and collaborative environment, is posited as an essential mediator in this process. Furthermore, the provision of robust professional development and consistent recognition for achievements are identified as vital levers for preventing stagnation and building a sense of purpose.

These factors are interconnected and must be addressed holistically, especially given the unique socio-economic and structural challenges of the Slovak context. Our work underscores that a successful strategy to improve engagement must be tailored to these specific national circumstances, rather than adopting generalized solutions from other healthcare systems. This paper's primary contribution is to systematically map these theoretical relationships, thereby creating a fertile ground for future empirical research. The validation of the hypotheses presented here will be crucial for moving this discussion from a theoretical framework to a data-driven imperative, providing actionable evidence for improving the sustainability and performance of Slovak healthcare.

Integrating sustainability principles into healthcare necessitates a comprehensive approach, encompassing resource efficiency, waste reduction, and workforce well-being (Woeber, 2013).

How Artificial Intelligence is Changing the Future of Human Resource Management and the Labour Market

***Ľuba* Tomčíková**[1,*]**, *Daniela* Bertová**[1]**, and *Jana* Cocuľová**[1]

[1] University of Prešov in Prešov, Department of Management Faculty of Management and Business, Konstantinová 16, 080 01 Prešov, Slovakia

Abstract

Research background: Artificial intelligence is revolutionising the field of human resource management. Traditional human resource management methods rely on manual processes and intuition, AI enables the automation and optimization of multiple processes in human resource management, especially in the areas of recruitment, selection, training and employee development. These technologies enable them to find, select, and train talented people faster and more efficiently, improving their overall results.
Purpose of the article: The aim of this article is to analyse and evaluate the potential impact of AI on the labour market, which is changing the future of human resource management to a high degree. At the same time, to highlight the results of surveys already conducted that assess the potential impact of AI in management.
Methods: The analysis of the theoretical knowledge of several foreign scientific research papers and studies points to the most interesting outcomes and claims in the area under study in the theoretical plane. At the same time, by analyzing these studies, the paper evaluates and presents the results of the research already conducted in the field of AI and HRM research, as an important trend of the present time and points out the possible implications in the future.
Findings & Value added: The benefits of AI in HR are immense, and it's time for companies to invest in these technologies to improve their workforce and stay competitive in today's rapidly changing business environment. The results of global surveys point to the fact that artificial intelligence is used more in some areas of HRM and less in others. However, it can only be concluded that the reasons for using AI in different areas of business will become more and more over time, despite the potential barriers and risks it brings with it. Finally, as AI becomes more integrated into HR practices, it will free up HR professionals to focus on more strategic initiatives and improve the overall effectiveness of the HR function.

Keywords: Artificial intelligence, Human resources management, Future trends

JEL classification: M00, M1, M12

1. Introduction

Artificial intelligence (AI) is key in human resource management in today's competitive business environment. Tecuci (2012; Soni 2022) states that AI is a rapidly developing technology enabled by the Internet that will soon have a profound impact on our daily lives. AI traditionally refers to an artificial creation of human intelligence that can learn, reason, plan, perceive, or process natural language. Such characteristics enable AI to bring enormous socioeconomic opportunities and socioeconomic challenges. According to Ilyas and Qadir (2024), AI is an emerging trend in human resources that has emerged as a recent phenomenon. However, it has significantly impacted people management and is seen as key to recruiting, training, developing and retaining employees in the workplace. Moreover, the current trend of incorporating machine learning and AI technologies into HR activities has the potential to lead to significant improvements in terms of increasing employee engagement and productivity in the workplace. Existing literature on artificial intelligence (AI) in human resource management (HRM) highlights its significant positive impact on the sector, with applications ranging from recruitment to

* Corresponding author: luba.tomcikova@unipo.sk

training and development. However, there remains a significant research gap in a comprehensive understanding of the coherent and procedural structure governing the integration of AI into HRM. While studies acknowledge the potential benefits of AI, such as workload reduction, data analysis, and improved decision-making, deeper research on the strategic implementation and organizational impact of AI in different areas of HRM is lacking. Moreover, the literature suggests that despite the expectation of widespread adoption of AI, many businesses, especially in the recruitment process, have yet to fully embrace AI due to factors such as resistance to new technologies and lack of established applications (Ilyas & Qadir, 2024).

1.1 Artificial intelligence and human resources management

Artificial Intelligence is gradually becoming a phenomenon that is revolutionizing the area of HRM by providing efficient solutions for the management of people across industries. Most of the HR activities, for instance, recruitment, performance management, and employee training and development, have always been cumbersome and labor-intensive.

Human resource management is a separate and specialized function that all managers must perform. It is the branch of management that deals with the recruitment, selection, development and best use of employees. Thus, human resource management ensures that each employee makes the maximum contribution to the achievement of the organization's goals. Human resource management as we know it today is the result of several major interrelated developments since the industrial revolution (Soni, 2022).

Artificial intelligence consists of applications that operate autonomously, can adapt and make predictions or decisions, provide recommendations, or generate content such as text or images. AI enables automated problem solving to achieve a specific goal. Well-known AI applications include, for example, ChatGPT or Microsoft Copilot. Also consider using AI in the context of HR metrics, such as data-driven approaches to HR or HR analytics.

AI technologies offer significant opportunities to improve human resource management functions such as recruiting and talent acquisition, employee training, and more. We live in an era where AI capabilities are reaching new dimensions and are having a profound impact on how our businesses operate and will operate. HR leaders believe that the merging of AI with core HR functions will be an asset and a significant trend that will improve the overall employee experience. It will provide more capacity, more time and budget, and more accurate information to manage people decisively. According to Nilsson (2005), machines will be able to perform most of the tasks required by human intelligence, what we call human-level AI.

Existing literature points to several benefits of AI adoption, which include increasing business productivity by optimizing business operations and resources (Faulds, Raju 2020), business model transformation/reengineering (Duan et al., 2019), reducing employee costs and improving employee experience, job satisfaction, and customer service (Bughin et al., 2017; Faliagka et al., 2014). This has led to the increasing use of AI-based solutions in sub-functional areas of human resource management such as talent acquisition, video interviewing, employee training and development (Maity, 2019), performance appraisal, talent prediction (Upadhyay, Khandelwal, 2018). In this regard, recent reviews have outlined the role of AI in facilitating HR analytics and the impact of AI-based technologies on HR management processes and practices (Vrontis et al., 2021). These opportunities will be described in more detail in the following section.

1. Human Resources Strategy and Planning

Strategic human resource management planning is the initial function for human resource management. Managers use artificial intelligence technologies to assist in the decision-making process in order to achieve the most effective strategic planning. Data mining and knowledge discovery tools are used to gather data from both internal and external sources. This helps to aggregate the information needed to understand the current state of human resources and to predict, evaluate, and adjust the future management of the company. A report containing the necessary information is compiled with the help of statistical and modification functions of an intelligent decision support system (Kumari & Hemalatha, 2021).

2. Recruitment and Selection

As artificial intelligence can provide decision support systems that help map the most suitable professional profiles for a given job and reduce the average time to complete recruitment activities, it can be a powerful tool in recruiting and selecting suitable candidates. AI will help map the most suitable

professional profiles for a given job role. A decision support system could be developed using fuzzy logic, artificial neural networks, expert systems or genetic algorithms. AI can be used to create a virtual assistant that can answer questions posed by candidates, evaluate the actions of talented candidates in real situations (Jatoba et al., 2019). When it comes to recruitment and selection, AI enables the creation of a model of the ideal candidate by cross-referencing information about a company that has been profiled in the past. This approach then compares candidates for new job openings in terms of tests, experience, and information related to overall curriculum. It is useful to analyze each candidate in terms of how suitable they are to fill a vacancy in the (Jha et al., 2020).

3. Training and Development

During the training process, the robotic training instructor can use the visual scanning system to monitor each employee's daily learning progress, accurately calculate their overall level of attention as well as adjust the level and rhythm of instruction based on feedback from the employee being trained. In addition, a corporate trainer can use data analytics to decide which employees need to learn from a vast knowledge base, create customized curriculums for employees, and use technology to test and assess employee levels in a comprehensive manner. AI-enabled instructors can also become all-around helpers, capable of performing tasks such as assessing employee data and creating high-quality reports on their progress (Chen, 2022).

4. Performance Management

In an intelligent decision support system, the use of 360-degree approaches to performance appraisal as scientific methodologies can enable automated and successful employee performance appraisal. An intelligent decision support system is equipped with employee performance appraisal criteria and any other relevant data to develop performance appraisal findings (Tewari & Pant, 2020). At the beginning of the year, the goals of the enterprise can be mapped and written down. Subsequently, the system can perform a comprehensive analysis and evaluation based on individual performance goals, department head ratings, feedback from colleagues, and other selected criteria (Jia et al., 2018).

5. Compensation Management

The use of AI technologies in the employee remuneration process can help ensure fairness in reward management (Tewari & Pant, 2020). Using big data as input, artificial neural networks can be designed to be used as intelligent decision support systems, which can then be used to create a fair reward assessment system.

The following table (Table 1) provides an overview of the human resource management landscape before and after the integration of AI, highlighting the significant improvements and challenges that need increased attention in order to successfully manage this transition.

Table 1. An overview of the human resource management landscape before and after the integration of AI

Transformed HR Practice	Traditional Approaches	AI-Enhanced Approaches
Administrative Task Automation	Manual and laborintensive management of payroll, benefits administration, and data entry, with high error risk and timeconsuming processes.	AI automates repetitive administrative tasks, analyzing vast datasets to deliver conclusive results with consistent performance and without fatigue, significantly reducing errors and saving valuable time, allowing HR managers to focus on strategic objectives.
Recruitment and Selection	Manual, timeconsuming, and tedious process; difficulty in managing a large volume of applications; potential for selection bias.	AI facilitates the handling of large volumes of applications, enhances communication with candidates, organizes interviews, improves recruitment efficiency, reduces biases through skill matching and automated data analysis, saves time and money, and promotes diversity and inclusion in the recruitment process.
Career Management	Advancement is based on hierarchy and direct human interactions.	AI supports personalized guidance services, data analysis for tailored career paths, and proactive succession management through predictive analytics, optimizing guidance resources.

Training and Development	Traditional training methods do not meet personalized needs.	AI enables personalized training offerings through mobile coaches, optimizing learning efficiency. It also facilitates certification and skill acquisition via flexible programs tailored to individual needs.
Talent Management	Performance evaluations are primarily by supervisors, subject to subjectivity.	AI transforms dynamic talent management by predicting needs and customizing development paths and daily tasks, thus fostering better staff retention.
HR Planning	Focused on manually assessing future workforce needs.	AI uses predictive analytics and talent personalization to improve team collaboration and efficiency.
Workplace Quality of Life Management	Focus on manual evaluations and interventions, centered on ergonomics, health and safety, and employee satisfaction surveys.	AI leverages facial recognition, text analysis, and natural language processing technologies to assess psychoemotional states, improving understanding of employee needs and offering personalized solutions to enhance workplace quality of life.
Performance Management	Focus on past performances with annual evaluations.	AI is used for real-time feedback and data-based performance analysis.
Enhancing Employee Behavior	Approaches centered on reward equity, skill development through training, and managerial recognition.	AI's analysis of data, sentiments, and morale to predict and improve employee behavior, automated environments, and virtual assistants facilitate personalized interactions with HR departments.
Ethical and Legal Principles	Management of expectations and communication to prevent misunderstandings based on psychological and legal contracts.	AI integration while navigating ethical dilemmas (algorithmic bias, fairness, privacy, and discrimination) requires transparent AI systems, bias audits, clear data use policies, and a strong ethical culture.

2. Methods

The aim of this article is to analyse and evaluate the potential impact of AI on the labour market, which is changing the future of human resource management to a high degree. At the same time, to highlight the results of surveys already conducted that assess the potential impact of AI in management. The analysis of the theoretical knowledge of several foreign scientific research papers and studies points to the most interesting outcomes and claims in the area under study in the theoretical plane. At the same time, by analyzing these studies, the paper evaluates and presents the results of the research already conducted in the field of AI and HRM research, as an important trend of the present time and points out the possible implications in the future.

3. Results

The following section presents the results of surveys that have already been conducted to assess the potential impact of AI on human reource management. In this article, we would like to highlight a study that includes the report which is based on data from a representative survey of businesses in Austria conducted in November and December 2024. The baseline questionnaire was developed by The Service Desk for Artificial Intelligence set up at RTR. The survey was carried out by the Market Institute1 via telephone interviews using CATI (computer-assisted telephone interviewing). Due to the focus on internal human resources management, the survey focused on companies with 50 or more employees. The Market Research Institute carried out a random selection of undertakings and applied weighting adjustments to ensure representativeness. A total of 701 interviews were conducted with the selected enterprises. The interviews focused on the head of the department responsible for human resources. Prior knowledge of AI or AI law was not a requirement for participation. The following Figure 1 shows the fact that: *For what purposes does your company, or an external service provider acting on your behalf, utilize AI in the area*

of HR? We can observe that the surveyed companies, to a large extent, do not use AI for any human resource management purposes, or, alternatively, use AI in the process of solving routine administrative tasks.

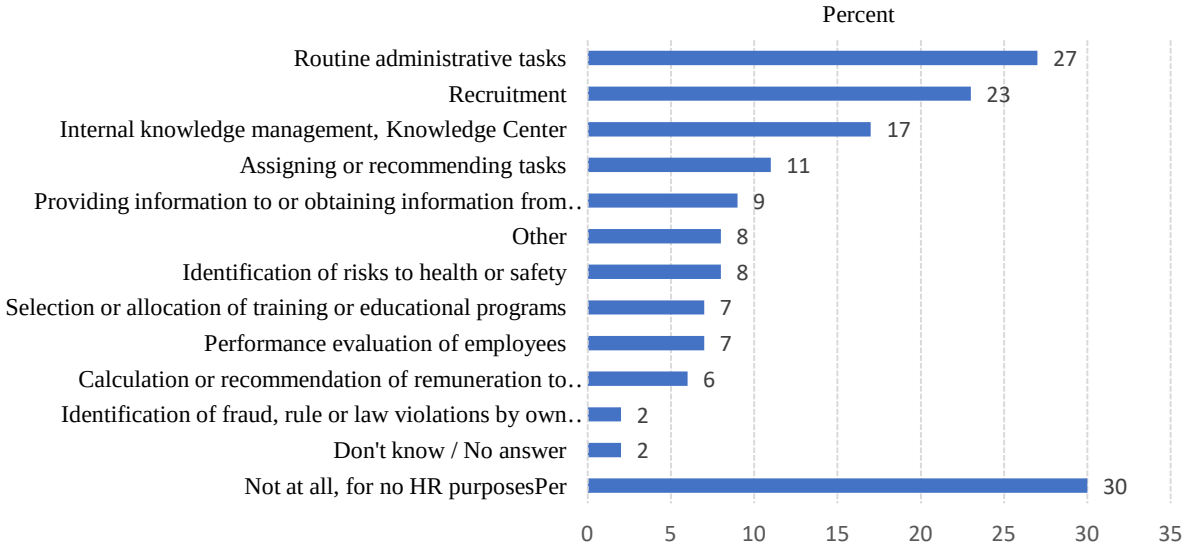

Figure 1. Areas of human resource management where artificial intelligence is used
Source: own processing according to www.rtr.at (2025)

Artificial intelligence provides a number of benefits to human resources. In an ever-changing business environment, staying competitive can be challenging. That's why artificial intelligence is becoming increasingly important in HR, providing professionals with the tools to offer scalable, immersive, and personalized learning solutions for their work teams. From streamlining recruitment processes to reducing unconscious biases in hiring, implementing AI in HR can bring a number of benefits to companies, ultimately leading to increased efficiency and productivity. Why the companies surveyed most often use AI in the HR area can be seen in the following Figure 2. Almost half of the company indicated cost saving, reduction in personnel costs, time savings.

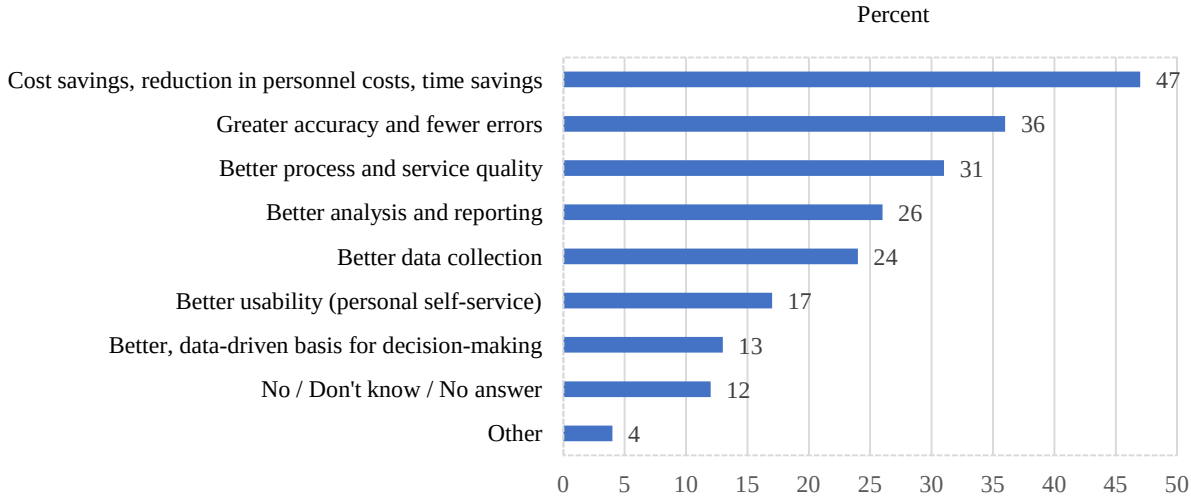

Figure 2. Reasons for using AI in a business
Source: own processing according to www.rtr.at (2025)

The following Figure 3 points out the possible barriers identify in the use of AI in HR. Based on the survey conducted, the following were identified:concerns about violation of data protection or privacy, lack of specialised knowledge or expertise in the company, too many legal requirements or unclear legal consequences, ethical concerns, poor traceability of results, concerns about inadequate or incorrect

outputs or decisions, difficulties with the availability or quality of required data, complex integration of existing data, devices, systems or software, reservations on the part of the workforce, employee representatives or management, potential discrimination, e.g. with regard to gender, age or disability and others. In addition, data protection remains a critical issue as HR systems often handle sensitive employee information. Organizations must implement robust security protocols to mitigate these risks.

Figure 3. Barriers identify in the use of AI in HR
Source: own processing according to www.rtr.at (2025)

Another survey focused on the use of AI in HRM in 2024 to understand the views and knowledge of AI held by HR professionals in Australia, as well as how AI and other related technologies are being used in the practice of HRM in organisations in Australia. This resulted in 236 valid responses from HR professionals across Australia, representing all industries, public, private, not-for-profit and academic institutions, and a diverse spread of organisation size. The results of the survey point to the following facts:

- Most HR professionals feel they have only a basic or average understanding of AI. Approximately 20% of HR professionals in academic institutions and the private and not-for-profit sectors reported having a good understanding of AI. The public sector was the least knowledgeable, with 22.9% saying they knew little or nothing about AI, compared to 14.9% in the private sector.
- The majority of HR professionals (83.9%) felt that the use of AI 'makes the HR function more efficient', although most (42.6%) agreed with this statement only to some extent (31.5% agreed, 9.8% strongly agreed), suggesting that there may be reservations about when and how efficiencies could be achieved. Consistent with this response, 88.9% also responded positively that the use of AI allows the HR department to focus on more strategic or 'higher value' activities - 16.2% strongly agreed, 37.4% agreed and 35.3% somewhat agreed.
- HR practitioners were asked to identify the issues that concern them most when using AI in HRM. Participants cited data security and privacy as the most pressing concerns (65.8%). Subsequently, drawing AI from poor quality data or evidence when used in HRM was a significant concern for 49.3%, as were bugs in AI systems (45.2%) (The State of AI in Australian Human Resources, 2024).

4. Discussion

By leveraging AI, HR teams can streamline recruitment processes, provide personalized learning and development opportunities, and improve employee engagement and retention rates. Simply put, the future of AI in human resource management is promising. HR practitioners should be able to solve current problems and adapt to future solutions that artificial intelligence offers to improve organizational development programs for a skilled and motivated workforce. Future research on the implementation of AI in HRM should aim to reduce barriers and develop the topic through further theoretical and empirical

contributions. By combining quantitative information from surveys and qualitative insights from case studies and interviews in research, it is possible to provide a comprehensive picture of the dynamics of AI adoption in different business areas. It would be interesting to conduct such studies in different organisational contexts, including public sector institutions, not-for-profit organisations as well as SMEs.

Based on the analysed studies and papers, we point out several facts. Artificial intelligence will make recruitment and selection processes of human resources management more efficient in the coming years, which will make it easier and faster for HR managers to identify the most suitable or talented candidates for a given job position. Personalised training and development programmes, which are part of employee training in companies, will become more common as AI algorithms will be used in the process of analysing employee data and, not least, in the process of introducing tailored training programmes and plans for each team member. AI chatbots will provide employees with constant support day, night, throughout the week, helping them to solve even unexpected problems quickly and efficiently. Predictive analytics will be used to forecast employee turnover and identify at-risk employees, so HR managers will have no problem retaining talented employees. Performance management feedback will become more objective as AI-based solutions automate the collection of performance data and provide real-time feedback.

Conclusion

By leveraging AI, HR teams can streamline recruitment processes, provide personalized learning and development opportunities, and improve employee engagement and retention rates. The benefits of AI in HR are immense, and it's time for companies to invest in these technologies to improve their workforce and stay competitive in today's rapidly changing business environment. The growing use of AI in HRM is driven by its impressive track record and is expected to become standard across all businesses in the coming years. Artificial intelligence enables HR managers to minimize administrative tasks, make more informed decisions about hiring and recruiting, training, employee compensation, and generate valuable employee data in the cloud through human-machine learning collaboration. Of course, it's important to point out how individual AI applications that focus on human resources enhance favorable outcomes while mitigating adverse effects. The impact of the socio-technological environment, including effective training, dealing with anxiety, managing change and improving employee skills, can lead to positive outcomes. At the same time, it is equally important to consider individual employee factors such as his or her personality, emanation and emotional intelligence as they have the potential to influence business results.

Growth and Survival Strategies of Small and Medium-sized Enterprises in Slovakia

***František* Vrábl**[1,2,*] **and *Milan* Fiľa**[3]

[1] University of Žilina, Faculty of Operation and Economics of Transport, and Communications, Department of Communications, Univerzitná 8215/1, 010 26 Žilina, Slovakia
[2] Training & Consulting, s.r.o., Na Veľký Diel 3323/1, 010 08 Žilina, Slovakia
[3] College of Applied Psychology s. r. o., Akademická 409, 411 55 Terezín, Czech Republic

Abstract

Research background: Small and medium-sized enterprises (SMEs) remain the backbone of the Slovak economy; by 2025 they will account for more than 99% of all businesses and provide two to three jobs in the private sector in the EU and Slovakia. After the pandemic, SME investment activity has recovered and is currently 10% higher than before 2020, while financing constraints have fallen to historically low levels (<0.1% of firms according to EIBIS). Nevertheless, high interest rates, increased regulation and a volatile global environment still limit access to traditional sources of financing.
Purpose of the article: The aim of the study is to analyze the growth and survival strategies of Slovak SMEs, with particular attention to the potential of alternative forms of financing and the development of the capital market in conditions of economic uncertainty.
Methods: A qualitative analysis of secondary data from the Web of Science, OECD and EIB databases was used - including the latest SME financing score and official reports from the ministries of the Slovak Republic. The comparative analysis covers a comparison of the Slovak environment with developments in the Czech Republic, Hungary and Poland. The research is analytical, without primary data collection.
Findings & Value added: Slovak SMEs are still mainly dependent on bank loans in 2025, but only ~5% use the capital market. The main barriers remain high transaction costs, complex legislation and low financial literacy of entrepreneurs. Digitalization and climate resilience are growing rapidly - over 76% of companies have applied advanced technologies and 25% have taken steps in the field of climate adaptation. International examples show that targeted government programs (IPO funds, tax breaks, education) significantly improve SMEs' access to alternative capital. The research brings specific recommendations for policymakers: establishing a pre-IPO fund, introducing legislation for REITs/SICAVs, expanding investment literacy, and developing digital capabilities. The implementation of these measures will increase the competitiveness of SMEs and support the long-term diversification of growth sources in Slovakia.

JEL classification: G24, G32, G38, L25

1. Introduction

Small and medium-sized enterprises (SMEs) are the backbone of nearly every modern economy. In the European Union, they account for over 99% of all businesses and provide approximately two-thirds of all private-sector jobs, contributing critically to stability, innovation, and social cohesion (Eurostat, 2024). In Slovakia, SMEs constitute an even larger share, representing 99.9% of active enterprises, generating over half of the nation's added value, and employing about 74.5% of the business workforce (European Commission, 2021). Recent data confirms that post-pandemic SME activity is recovering, with projected employment growth of 0.9% and real value-added growth of 1.7% for Slovak SMEs this year. Micro-

* Corresponding author: mail@trainingconsulting.sk

enterprises are leading this rebound, outperforming larger categories in both employment and value added (Slovak Business Agency, 2021). Their growth and survival have a direct impact on the competitiveness and innovative capacity of the country.

Despite their economic importance, Slovak SMEs face persistent challenges. Nearly 75% of new small businesses fail within five years, with failure rates peaking in the critical third year (Kalemli-Ozcan et al., 2020). Key risk factors are low profitability, poor liquidity, and high debt levels. Traditionally, Slovak SMEs have relied almost exclusively on bank loans, with only about 5% accessing capital markets. This reliance has been further strained by rising interest rates, inflation, and tightening credit standards (Slovak Business Agency, 2021; von Imhof, 2021). These financial constraints are compounded by systemic issues such as high tax and social security contributions, complex administrative procedures, and slow permitting and registration processes that hinder sustainable business development.

Research Question: How do Slovak small and medium-sized enterprises (SMEs) adopt growth and survival strategies, with a focus on the potential of alternative forms of financing and the development of the capital market in conditions of economic uncertainty?

The aim of this article is to analyze how Slovak SMEs manage growth and survival, focusing on evolving capital market conditions, best practices from neighboring countries, and pragmatic steps for integrating SMEs into alternative financing channels to boost their competitiveness and resilience (von Imhof, 2021).

1.1 New Trends and Challenges for SMEs

In 2025, Slovak small and medium-sized enterprises (SMEs) face significant strategic challenges due to new regulations and the need for rapid adaptation. A key development is the extension of obligatory ESG (Environmental, Social, and Governance) reporting to smaller businesses, which now requires them to document sustainability performance, energy consumption, carbon footprint, and social responsibility metrics. While these new compliance obligations present substantial managerial demands, they also offer an opportunity for organizational transformation (PwC Slovakia, 2021). To improve their survival prospects, Slovak SMEs need to focus on several critical areas. One of the most important is strengthening strategic management and accelerating digitalization. According to recent OECD assessments, only 13% of Slovak businesses are considered highly digitalized, which is well below the EU average of 18% (OECD, 2021). On the other side, in recent years, we have noticed an increase in the importance of the shared economy, which has seen significant growth with the development of online platforms and which, with its disruptive approach, is becoming a new economic phenomenon (Viglaský, & Tóthová, 2024). This lag in digitalization represents a critical vulnerability in their competitiveness and highlights a need for a concentrated effort to adopt modern digital tools and processes. The continued growth and sustainability of these businesses will depend on their ability to adapt quickly, embrace these tools, and comply with evolving regulatory frameworks (SDA Bocconi, 2025; Eutech, 2025; Bianchini, & Sancho, 2025). Support initiatives are being introduced to help SMEs navigate this complex environment. For example, the national "Green for Businesses" program, launched in May 2025, provides financial and technical assistance to SMEs for investing in renewable energy systems. This not only helps them reduce operating costs but also lowers their environmental impact (Slovak Business Agency, 2025; Stavebný magazín, 2025). By taking advantage of such programs and integrating ESG policies into their daily operations, SMEs can improve their long-term viability and contribute to a more sustainable economy.

2. Methods

This research employs a strictly qualitative and analytical approach, structured around three key pillars to provide a comprehensive analysis of the Slovak small and medium-sized enterprise (SME) sector. The qualitative methodology is grounded in established research designs that emphasize depth of understanding through secondary data interpretation and systematic synthesis (Klein & Todesco, 2021).

2.1 Secondary Data Analysis

The investigation relies on the most current secondary data from leading international organizations, including the OECD, the European Commission, the World Bank, and Eurostat, as well as official Slovak policy documents, such as the SME Fact Sheet 2025. These sources offer a comprehensive macroeconomic, policy, and business environment context for the Slovak SME sector. The analysis covers critical areas such as SME performance, access to finance, innovation, and the regulatory and

administrative landscape. Secondary data analysis provides a robust, evidence-based foundation for understanding the current state and challenges facing Slovak SMEs (OECD, 2021).

2.2 Comparative Analysis

To contextualize the findings, this study includes a comparative analysis of SME development and capital market trends in the Czech Republic, Hungary, and Poland. These countries were chosen because of their geographical proximity, shared historical and policy backgrounds, and similar economic structures. The benchmarking process focuses on comparing policy reforms, the evolution of alternative financing channels, and best practices in SME support frameworks. Comparative case analysis is recognized as a powerful method to derive transferable insights across similar economic contexts (Saunders, Lewis & Thornhill, 2019)

2.3 Literature Synthesis

A systematic review and synthesis of peer-reviewed literature were conducted with explicit focus on Q1 and Q2 journal articles indexed in the Web of Science Core Collection. This analytical approach enabled targeted selection of high-quality, rigorously reviewed studies with direct relevance to the strategic growth of SMEs in Slovakia. Concentrating on publications between 2020 and 2025 captures contemporary empirical insights reflecting post-pandemic turbulence and simultaneous emergence of technological, regulatory, and sustainability-driven demands. The literature synthesis further validates the multidimensional pressures faced by SMEs and the centrality of dynamic adaptation strategies (Klein & Todesco, 2021) The methodology underlying this synthesis is strictly analytical, with no reliance on primary data collection such as surveys, interviews, or experiments. This ensures that the perspective remains objective, evidence-driven, and verifiable against established secondary sources. (Creswell & Poth, 2018)

3. Results

3.1 The Dominance of Bank Financing

Slovak small and medium-sized enterprises (SMEs) remain heavily dependent on bank financing. Approximately 76% of their financial resources came from bank loans as of 2025. This reliance mirrors a broader Eurozone trend, where bank lending is the dominant financing method for roughly 82% of businesses, according to surveys by the European Commission and the European Central Bank (ECB). However, a significant shift has occurred since the pandemic. Post-pandemic tightening of bank lending standards, increased risk-aversion, and rising interest rates have made it more difficult for SMEs to secure loans. The loan application rejection rate for SMEs rose sharply from around 5% in the first quarter of 2022 to 16% in the second quarter of 2023, signaling a growing financing gap. As a result, an increasing number of Slovak SMEs are being forced to explore alternative financing mechanisms beyond traditional bank credit. This pie chart displays the breakdown of funding sources. The largest segment, Bank loans, is shown in blue and makes up 76.0% of the total. Other sources, represented in green, account for 19.0%, while the smallest portion, Capital market, is shown in orange at 5.0%. The chart clearly demonstrates that bank loans are the dominant source of funding.

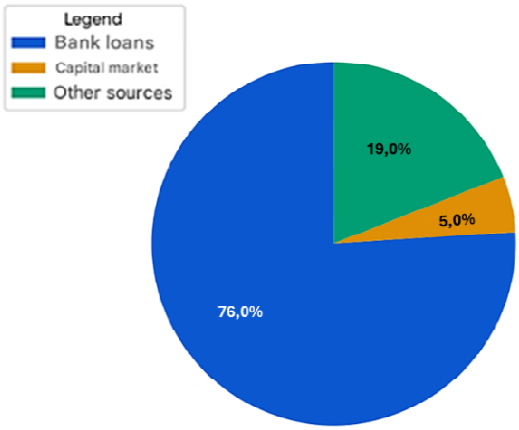

Figure 1. Sources of financing for small and medium-sized enterprises (SMEs) in Slovakia, 2025
Source: Slovak Business Agency (2025).

3.2 Barriers to Capital Market Entry

Despite the recognized benefits of capital market financing, such as access to long-term growth capital and risk diversification, Slovak SMEs face multiple, interconnected barriers to participation:

- **High Costs:** The initial and ongoing costs tied to initial public offering (IPO) processes, compliance, and maintaining public company status can be prohibitively high, especially for smaller firms.
- **Complex Regulations:** European regulations like the Market Abuse Regulation (MAR) and the Prospectus Directive require significant administrative compliance. This often demands costly legal and financial expertise that is often beyond the capacity of many SMEs.
- **Lack of Specialized Advisory Services:** SMEs frequently struggle to afford or access the specialized legal, accounting, and advisory firms that are essential for a public listing, which increases the complexity and risk of market entry.
- **Low Financial Literacy and Trust:** A pervasive lack of sophisticated financial knowledge among SME owners, coupled with limited trust in capital markets and institutional investors, further hinders active participation.
- **Emerging ESG Requirements:** New environmental, social, and governance (ESG) reporting obligations add another layer of compliance. While they increase operational burdens, they also offer pathways to ‘green’ financing, which few SMEs have yet been able to utilize.

3.3 Examples from Neighboring Countries

Several policy initiatives from Central and Eastern European neighbors illustrate actionable measures Slovakia could adopt:

- **Czech Republic:** The National Development Bank has established an IPO fund that provides capital support and helps cover SMEs’ upfront IPO costs. They also created an accessible online "Capital Guide" portal that educates SMEs about alternative financing and compliance steps, which boosts financial literacy.
- **Hungary:** Hungary's robust SME strategy includes a mentoring program designed to prepare SMEs for public offerings and a dedicated National Stock Exchange Development Fund, which co-invests in prospective IPO companies to mitigate risks and boost confidence.
- **Poland:** The government has implemented a dedicated SME Capital Market Development Strategy, which includes tax incentives for investors supporting small and medium-sized enterprises and simplified regulatory procedures for firms entering alternative trading platforms like NewConnect. Additionally, Poland’s state-backed financial institutions actively promote venture capital and mezzanine financing schemes, ensuring that innovative SMEs can access growth capital without excessive administrative burdens.

These regional best practices demonstrate that combining financial incentives, education, and public-private co-investments can effectively lower barriers and stimulate SME integration into capital markets.

Table 1. Overview of companies in the V4 countries

Enterprise size	Czech republic		Hungary		Poland		Slovakia	
	Number of enterprises	% share	Number of enterprises	% share	Number of enterprises	% share	Number of enterprises	% share
Micro enterprises	1 080 000	97.4%	924 000	88.4%	1 350 000	61%	220 000	77%
Small enterprises	34 000	3.1%	67 000	6.4%	650 000	29%	40 000	14%
Medium enterprises	6 825	0.6%	54 000	5.2%	210 000	10%	26 500	9%
SMEs total	1 120 825	1	1 045 000	1	2 210 000	1	286 500	1

Source: Eurostat. (2024)

Table 1 shows the structure of enterprises in the V4 countries based on enterprise size. This is most pronounced in the Czech Republic (97.4%) and Hungary (88.4%), which highlights their dependence on very small enterprises. In contrast, Poland has a more balanced structure, with micro-enterprises representing a smaller share (61%) and a larger share of small (29%) and medium-sized (10%) enterprises. Slovakia is located between these extremes, with micro-enterprises accounting for 77% of the total.

Table 2. Comparative analysis of access to financing and support for SMEs in the V4 countries

Country	Dominant source of financing	Barriers to entering the capital market	Examples of good practices
Slovakia	Bank loans (~76%)	High transaction costs	Use of R&D tax incentives
		Comprehensive legislation	Focus on public support through EU structural funds
		Low financial literacy	
Czech Republic	Bank loans, leasing, factoring, alternative sources (venture capital, crowdfunding)	Lack of capital for start-ups	IPO fund to cover initial costs
		Low knowledge of new financial instruments (IPOs, debt securities)	Online portal "Capital Guide" increasing financial literacy
Hungary	Bank loans, state subsidies and guarantee programs	Lack of capital for SME development	National Stock Exchange Development Fund (including investments in IPOs)
		The need to support green and innovative investments	Mentoring program for preparation for public offerings
Poland	Bank loans, leasing, grants, alternative sources (venture capital, factoring)	High taxes and levies Legal uncertainty and regulatory complexity High labor costs	SME Liquidity Support Programs Growing Investment in Technology Startups and Green Projects

Source: Eurostat. (2024)

Table 2 describes the financial environment for businesses in the V4. It highlights that bank loans are the main source of financing in all four countries, with Slovakia showing the highest dependence (76%). Key barriers to capital market entry include a lack of capital for startups, high transaction costs and low financial literacy. The table also identifies country-specific challenges, such as Poland's high taxes and regulatory complexity and Slovakia's problems with complex legislation.

4. Discussion

The findings of this study confirm that the high dependence of Slovak SMEs on bank loans significantly restricts their resilience and growth potential in the face of contemporary economic shocks such as inflationary pressures, rising interest rates, and post-pandemic market volatility. Empirical evidence highlights that firms which actively diversify their sources of capital—including engaging with the capital markets and alternative funding instruments—tend to experience higher sustainable growth, improved financial stability, and greater adaptability.

International case studies and policy analyses demonstrate that transformative improvements are attainable through a multi-faceted approach combining legislative reform, public-private partnerships, and financial literacy initiatives. These elements can collectively dismantle the key obstacles of high costs, regulatory complexity, and information asymmetry that continue to limit SME participation in capital markets. Leading international institutions emphasize several priority actions:

- The World Bank advocates for a national capital market development strategy that facilitates cooperation between public authorities, private investors, and business stakeholders to create an SME-friendly financing ecosystem.
- The European Union's Technical Expert Stakeholder Group (TESG) for SMEs recommends measures such as regulatory simplification, enhanced pre-IPO support programs, and the introduction of fiscal incentives to stimulate SME access to capital market financing.

Specific examples from Central Europe illustrate successful policy frameworks:

- In Hungary, the National Stock Exchange Development Fund plays a pivotal role by providing co-investments in SMEs preparing for IPOs, effectively reducing financial barriers and sharing risks. This is complemented by a mentoring and refinancing scheme which offers professional advisory services and reimburses up to 50% of IPO-related costs, alleviating both financial and knowledge constraints.

Countries should learn from examples of best practice, identify successful strategies that can be adapted or replicated in their own conditions. (Kučera et al, 2023). Adopting these international best practices in Slovakia could substantially enhance SME financing dynamics by:

- Removing financial and administrative barriers through tailored funding instruments such as pre-IPO funds, co-investment vehicles, and tax-advantaged financial products like REITs and SICAVs.
- Establishing comprehensive educational and advisory platforms to improve financial literacy, ESG integration, and investor relations skills among SMEs.
- Fostering greater collaboration between public entities and private investors to design scalable, sustainable support systems that align with the Slovak economic context.

Implementing such policies would not only empower Slovak SMEs to better access alternative capital but also contribute to building a more diverse, innovative, and resilient national economy capable of withstanding future global shocks and enhancing long-term competitiveness.

Conclusion

To secure sustainable long-term growth and economic stability, Slovak small and medium-sized enterprises (SMEs) must transition from an overwhelming dependence on bank financing toward a diversified financing ecosystem that includes capital markets, alternative financial instruments, and domestic capital mobilization. The findings of this study show that Slovak SMEs remain predominantly reliant on traditional bank financing in 2025, with approximately 76% of their financial resources coming from bank loans, while only about 5% use the capital market. This dependence limits their resilience and growth potential, especially in a volatile economic environment.

Slovakia should develop and adopt a comprehensive national capital market development strategy in close collaboration with the European Union to ensure alignment with EU fiscal and regulatory frameworks. This strategy is fundamental to establishing a stable macroeconomic environment and robust legal infrastructure, prerequisites for an effective and SME-friendly capital market. Through this, SMEs would gain access to diverse and long-term funding options, crucial for supporting innovative, growth-oriented ventures that often lack traditional collateral.

To implement this strategy, Slovakia needs targeted legislative reforms introducing and modernizing financial instruments such as Real Estate Investment Trusts (REITs) and updated Sociétés d’Investissement à Capital Variable (SICAV) funds. Additionally, the creation of a state-backed pre-IPO fund is imperative to offset the high initial costs associated with public listings for promising SMEs. Such a fund would reduce investor risk, improve market confidence, and encourage private capital deployment at scale.

Mobilizing domestic capital is essential for strengthening the SME financing landscape. Slovakia should explore mechanisms to engage its pension funds and expand offerings of retail government bonds aimed at directing local savings toward domestic enterprises and infrastructure investment. Recent government proposals envisage allowing voluntary pension contributions into national growth projects (including housing, transport, and energy infrastructure), capped initially at around 5%, thus bridging long-term financing gaps and supporting economic resilience.

Concomitant to financial reforms, significant resource allocation should be invested in entrepreneurship and investor education. The importance of education at every age, and especially in seniors, is also confirmed by research by Bursová et al (2024). As the authors Kondrla et al. (2023) claim, The starting point is a reflection on the philosophical background of education as a repetition and production of the same. Dedicated online portals, regional workshops, and analytical reporting platforms can significantly raise financial literacy, ESG competence, and investor transparency—key prerequisites for vibrant capital markets. Enhanced visibility for SME entrants through analytical reports would empower investors with better decision-making tools and augment market liquidity.

The coordinated implementation of these recommendations will not only reinforce the financial foundation and growth capacity of Slovak SMEs but will also contribute materially to the overall competitiveness and economic dynamism of Slovakia. By broadening financing sources and fostering a supportive ecosystem, Slovakia can better enable its SMEs to innovate, scale sustainably, and withstand future economic disruptions.

Acknowledgements

The authors would like to express their sincere gratitude to Training & Consulting, s.r.o. for their financial support in the preparation of this article. Their commitment to discovering and developing alternative financial solutions for small and medium-sized enterprises in Slovakia is crucial for the realization of this research.

Benefits of Using Key Performance Indicators in Management Process in Industrial Enterprises

***Tsanka* Zlateva-Petkova**[1,*]

[1] University of Gabrovo in Gabrovo, Department of Management, Faculty of Economics, 4 Hadji Dimitar str., 5300 Gabrovo, Bulgaria

Abstract

Research background: The exceptional usefulness of key performance indicators lies in the fact that they help each area of the business to develop at a rapid pace and implement the strategy chosen by the management for the prosperity of the organization. The key performance indicators are a quantifiable measure of effectiveness, defined and limited in time and tied to the achievement and implementation of a specific goal. They represent specific and real goals that management and work teams should strive for, stages for measuring progress and observations, insights and conclusions that help employees in the organization make optimal decisions. The application of key performance indicators is wide-ranging and covers almost all areas of company management - finance, human resources, marketing and sales, innovation and investment, production and process improvement.
Purpose of the article: The aim of this article is to present the real practical effectiveness of the application of key performance indicators as a well-planned and prepared roadmap, leading any organization, regardless of the subject of activity, to dynamic development and prosperity through strategic orientation and measurement of work results and progress in each area.
Methods: To achieve the goal, a combination of mixed methods was applied, combining qualitative and quantitative research techniques.
Findings & Value added: At the end of the article, observations and conclusions regarding the application of key performance indicators as a tool for forming good management decisions and correct choices for strategic growth in a number of industrial enterprises are summarized. These results were obtained from an empirical study using the survey method of 24 industrial enterprises from the central northern region of the Republic of Bulgaria.

Keywords: Efficiency, Industrial enterprise, Key performance indicators, Process improvement

JEL classification: L0, M21

1. Introduction

The use of key performance indicators (KPIs) offers numerous advantages for the rational management of organizations. As performance measurement tools, KPIs help allocate and direct resources effectively in the areas of their consumption, leading to improvements in processes, performance, and overall productivity (Deliu & Frasineanu, 2013; Bititci, Garengo, Ates, & Nudurupati, 2011). Over the past two decades, the concept of KPIs has evolved significantly, becoming a central element in performance management systems across various sectors (Parmenter, 2015; Marr, 2012).

KPIs are widely recognized as essential tools for aligning operational activities with strategic objectives (Kaplan & Norton, 1996). Their application spans not only private enterprises but also public sector organizations, where transparency, accountability, and resource efficiency are paramount (Micheli & Kennerley, 2005). A well-designed KPI system provides organizations with the ability to evaluate and monitor performance, but also to promote continuous improvement and innovation (Neely, Gregory, & Platts, 2005).

Recent studies emphasize the need for KPIs to be dynamic and adaptable, particularly in rapidly changing business environments characterized by digital transformation, stakeholder pressure, and

[*] Corresponding author: tszlateva@abv.bg

sustainability goals (Bititci, Garengo, Ates, & Nudurupati, 2012; Searcy, 2012). This requires integrating qualitative and quantitative indicators, including leading and lagging measures, to support both short-term operations and long-term strategic planning.

As already mentioned, the main use of KPIs is to measure and evaluate the effectiveness of work performance and to contribute to the coordination of goals and objectives across different departments. However, additional benefits can be achieved through the application of KPIs, such as:

- Real-time monitoring. KPIs enable tracking of project activities in real time and identifying critical issues early, which supports timely interventions (Benková, Gallo, & Nemec, 2020).
- Optimal distribution of activities and deadlines. KPIs help verify whether tasks are completed within the predefined time frame and detect potential delays or bottlenecks (Dominanta, 2015).
- Fairness and clarity in team operations. Transparent use of KPIs enhances collaboration, motivation, and accountability among team members (Rosová & Balog, 2012).
- Informed decision-making. Management benefits from specific, reliable, and timely information that enables strategic planning and risk mitigation (Folan & Browne, 2005; Gosselin, 2005).
- Resource allocation and optimization. KPIs support rational use of limited resources by identifying priority areas (De Toni & Tonchia, 2001).
- Continuous process improvement. Monitoring KPIs over time allows identification of trends and areas requiring corrective actions or optimization.
- Customer satisfaction insights. Customer-oriented KPIs provide valuable data on behavior and expectations, facilitating tactical changes to improve user experience and service quality (Zlateva-Petkova, 2024).

KPIs are more than numerical benchmarks – they are strategic tools embedded in performance culture. Their successful implementation depends on the clarity of objectives, data quality, and the organizational capacity to interpret and act upon KPI results.

2. Methods

This study investigates the application of key performance indicators (KPIs) as tools for enhancing efficiency and supporting management practices in technological enterprises located in the central-northern region of the Republic of Bulgaria.

A mixed-methods research design was employed, combining both quantitative and qualitative approaches to data collection and analysis. This design was chosen in view of the multifaceted operational contexts of the participating enterprises, which are involved in a variety of technological, industrial, and consultancy activities related to both engineering and management.

Data Collection. The primary source of empirical data was a structured survey questionnaire, designed to assess the level of implementation, perceived effectiveness, and challenges associated with KPIs in the surveyed organizations. The questionnaire included closed-ended questions using Likert scales, multiple-choice items, and dichotomous (yes/no) responses. The respondents were mid-level and senior-level employees, selected by enterprise management based on their engagement in operational and strategic decision-making.

Due to space constraints, the full version of the questionnaire is not included in this publication. Furthermore, a number of items in the instrument refer to broader organizational aspects that exceed the specific focus of this study and are therefore not discussed in detail.

Research Limitations. Several methodological limitations were encountered during the research process, primarily linked to data access and organizational constraints:

- The sample was limited to manufacturing and industrial enterprises, although KPIs are relevant across diverse organizational types.
- Survey participants were pre-selected by enterprise management, which introduces the risk of sampling bias and may affect the generalizability of the results.
- The fixed-response format of the questionnaire restricted the ability of respondents to elaborate on their views or provide additional insights, even when they expressed willingness to do so.

Enterprise Characterization. For the brief profiling of the surveyed enterprises, the following parameters were used:

(1) size of the enterprise, based on working capital and number of employees;
(2) participation in European-funded projects; and
(3) level of innovation activity, assessed by the scale of investments in production capacity renewal and technology acquisition or development.

3. Results

The high investment activity of the surveyed technology companies makes a good impression, given the stagnation of the markets, inflation and the crisis resulting from the Covid, the difficulties and the consequences of military activities on the territory of Ukraine. This is explained by the increased participation in European projects and other ways of financing business activities.

Twenty-four manufacturing enterprises from the industrial sector were asked to participate in the study on the implementation and effectiveness of the implementation of the key performance indicators. The enterprises vary in size, origin of capital, some of the enterprises are with mixed participation, and some of the enterprises are owned by foreign investors.

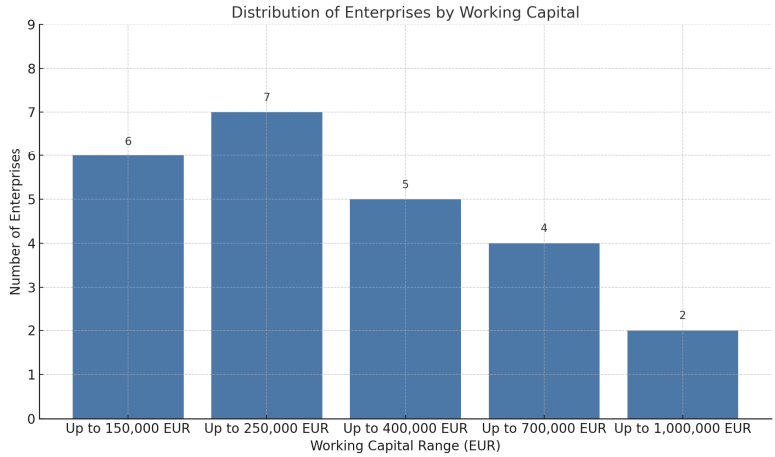

Figure 1. Number of enterprises according to working capital
Source: author (2025)

According to the amount of working capital (Fig. 1), the enterprises are divided into the following categories: up to 150,000 euros - 6 enterprises; up to 250,000 euros - 7 enterprises; up to 400,000 euros - 5 enterprises; up to 700,000 euros - 4 enterprises; up to 1,000,000 euros - 2 enterprises.

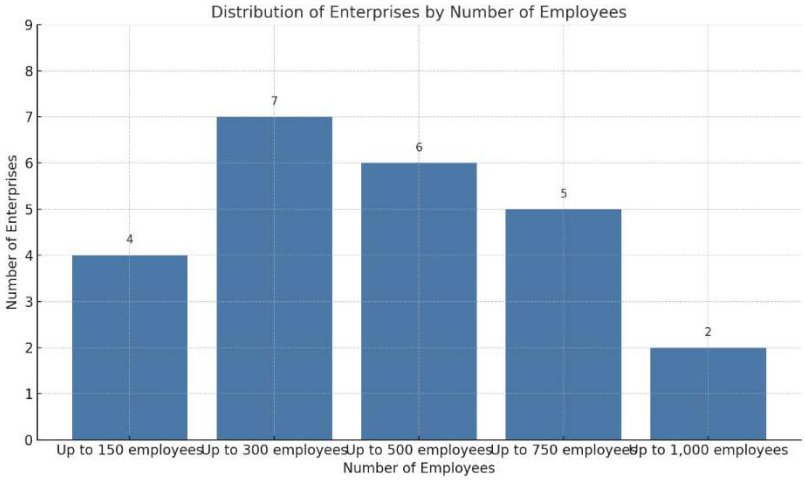

Figure 2. Sizes of enterprises by number of staff
Source: author (2025)

According to the number of personnel (Fig. 2), the enterprises are divided into five groups: up to 150 workers and employees - 4 enterprises; up to 300 - 7 enterprises; up to 500 - 6 enterprises; up to 750 - 5 enterprises; up to 1,000 - 2 enterprises.

The surveyed enterprises were also asked about their participation in European projects, as this implies that they meet specific requirements, as well as having the opportunity to apply modern methods, approaches and technologies in the exercise of their production activities. In their responses, some enterprises shared that they had not participated in European projects – 6 enterprises; 8 enterprises participated in up to 3 projects; 7 enterprises participated in up to 5 projects and only 3 enterprises participated in 6 or more projects (Fig. 3).

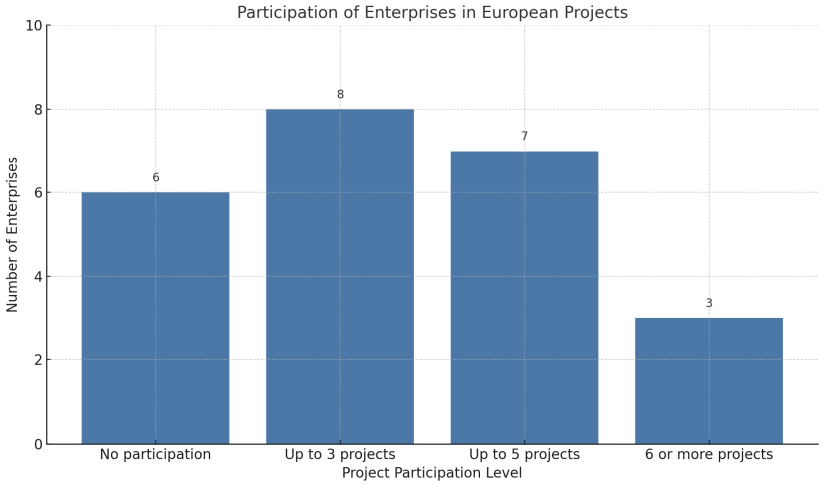

Figure 3. Distribution of enterprises in their participation in EU projects
Source: author (2025)

The research is interested in the innovation and investment activities of enterprises, as it provides some idea of the economic power of companies, as well as the understanding of the management teams that manage the processes and activities in enterprises. It is an indisputable fact that the use of modern technologies, materials and high-tech equipment leads to high quality of the products, as well as to higher final financial and production results

The following graphs present the responses to the survey on the funds invested in the renovation of production facilities. The results are presented in two versions - in value in euros and as a percentage of working capital.

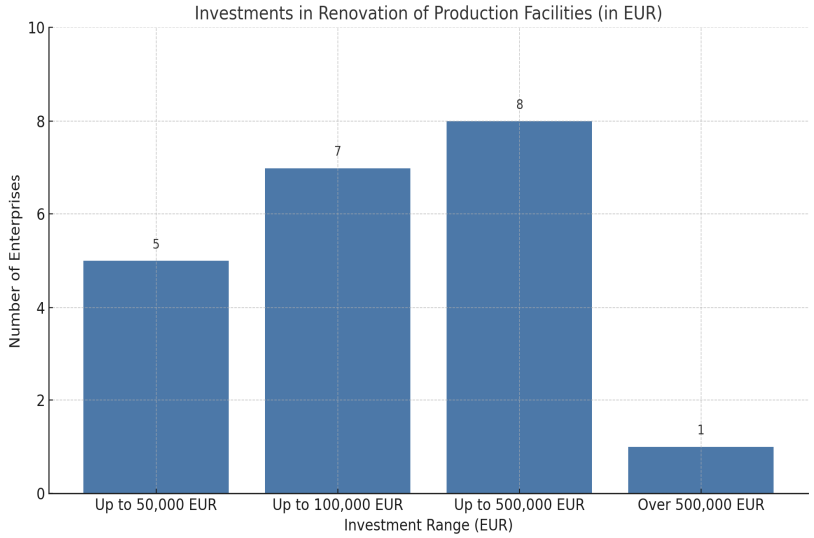

Figure 4. Investment in the renovation of production facilities in value
Source: author (2025)

The study shows that only five enterprises invest up to 50,000 euros to restore their technological equipment. Seven enterprises invest up to 100,000 euros, and eight enterprises allocate up to 500,000

euros. Unfortunately, the enterprises that can invest up to 500,000 euros in renovation are three, and only one enterprise could invest over 500,000 euros in its fixed assets (Fig. 4).

The distribution of the funds invested for the restoration and renovation of production facilities expressed as a percentage of working capital is as follows: up to 20% - 7 enterprises; up to 40% - 6 enterprises; up to 50% - 5 enterprises; up to 60% - 4 enterprises; and over 60% - 2 enterprises (Fig. 5).

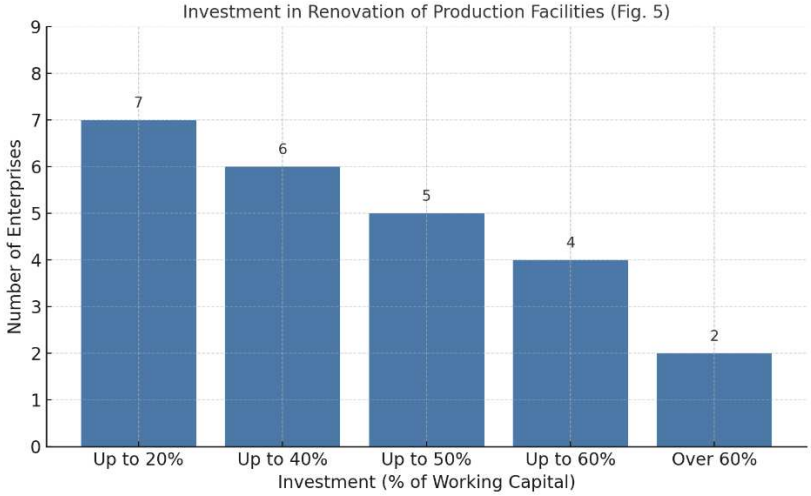

Figure 5. Investments in the renovation of production facilities expressed as a percentage of working capital
Source: author (2025)

The purchase and development of new technologies is an essential part of the investment and innovation practice in modern manufacturing enterprises. The current state of the surveyed enterprises is shown in the following two graphs using two approaches - in value in euros and as a percentage of working capital. Three of the enterprises have allocated up to 50,000 euros in the last reporting period for the development of new technologies, as this is an activity assigned to the technical specialists of the enterprises. Nine of the enterprises have invested up to 100,000 euros, and eight enterprises – 200,000 euros. Only four enterprises have purchased and developed new technologies for up to 500,000 € (Fig. 6).

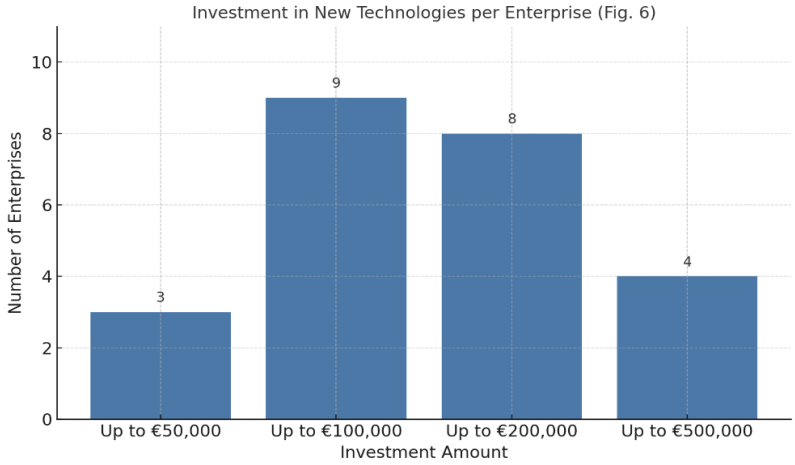

Figure 6. Purchase and development of new technologies in value in euros
Source: author (2025)

The distribution of funds for the purchase and development of new technologies expressed as a percentage of working capital is as follows: up to 20% - 5 enterprises; up to 40% - 8 enterprises; up to 50% - 7 enterprises; up to 60% - 4 enterprises (Fig. 7).

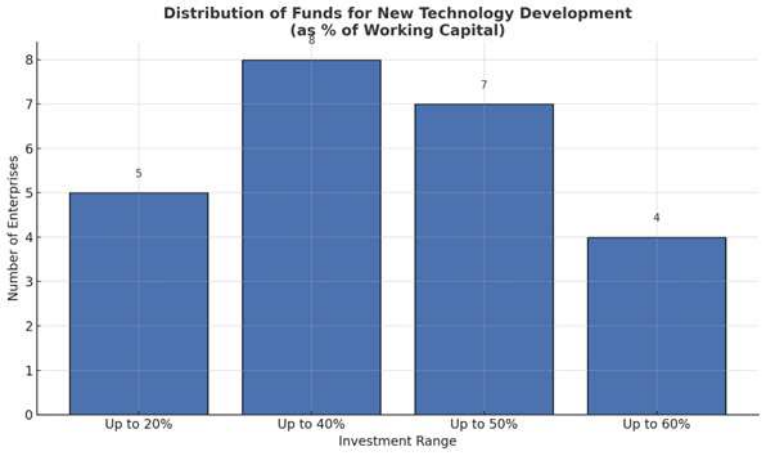

Figure 7. Purchase and development of new technologies as a percentage of working capital
Source: author (2025)

Key performance indicators are available in all possible combinations and their diversity stems from the different goals and needs of both the organization itself and the endless needs and demands of the customers that the organization is trying to satisfy. Key performance indicators are also distinguished by their complexity and size, since each of them serves to monitor a specific and specific goal in assessing the different aspects of the organization's activities. (Zlateva-Petkova, Ts., 2024)

This enables enterprises to define and rank key indicators themselves, which will lead to process improvement and increased efficiency. Since enterprises vary in size and economic power, it cannot be expected that the application of key indicators will be equivalent. The general conclusion is that all enterprises that have confirmed the use and application of key indicators have declared that this has led to increased performance and an increase in parameters such as market share, customer satisfaction, developing new products. In the field of work performance and human resources, enterprises have identified an increase in initiative and creativity, a desire for development and growth, and an increase in personal motivation.

Twenty-one of the companies confirmed that they use and apply key performance indicators in their management practice. It is worrying that four of these companies use such indicators only to manage their marketing activities. The remaining seventeen companies use key indicators in different areas of their management processes (Fig. 8).

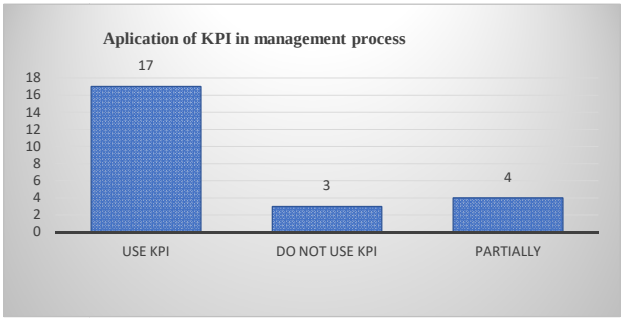

Figure 8. Application of KPI in the management process
Source: author (2025)

The following explanations and graphs will clearly and categorically demonstrate the relationship between KPIs and improved productivity of enterprises in several areas of their management process. Each graph and its comments describe the specific percentages by which the results in the studied areas have increased.

In the conditions of the difficult economic situation after the Covid crisis and the ongoing military operations on the territory of Ukraine, increasing the market share is a real success for any organization.

The studied industrial enterprises that use and apply KPI /21/ have reported an increase in their market share as follows: up to 20% - 6 enterprises; up to 35% - 7 enterprises; up to 50% - 5 enterprises and over 50% - 3 enterprises (Fig. 9).

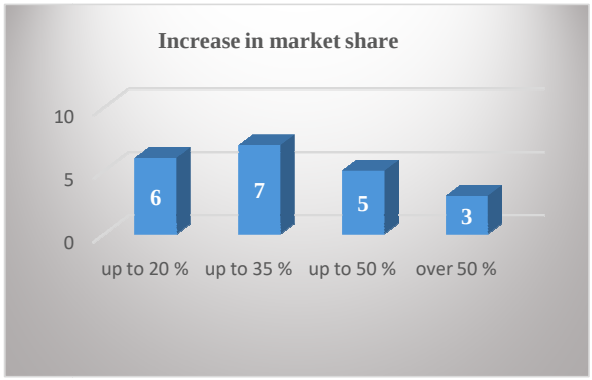

Figure 9. Increase in market share, in percentages
Source: author (2025)

An important indicator that testifies to the good condition and development trends is the development of new products for the last year of the reporting period. The surveyed enterprises confirm that they have worked on creating new products at the request of their customers. Because the capabilities of the surveyed enterprises are different, as are their products in terms of technical and production complexity, the number of new products developed is also different. Five of the enterprises have developed two new products. Seven enterprises have developed 4 products and also seven enterprises have developed 6 new products. Only two enterprises have developed more than 6 new products (Fig. 10).

Figure 10. New product development
Source: author (2025)

Due to the limitations of the scope of this publication it is not possible to present the key performance indicators explored in all areas. Therefore, we will indicate those key performance indicators that have led to increased competitiveness and increased market share of the industrial enterprises that were included in the survey.

1. Market Share Growth
2. Competitive Sales Growth Rate
3. Benchmarked Profit Margins
4. Customer Satisfaction Benchmark
5. Return on Investment (ROI) Benchmarking
6. Customer Retention Rate
7. Brand Equity Index
8. Earnings Before Interest and Taxes (EBIT) Margin Comparison
9. Capital Expenditure (CapEx) Efficiency
10. Market Position Rank

Customer retention is a key advantage in the conditions of increased competition and a wide range of high-tech products and increasing customer satisfaction in a difficult economic situation is a definite success. The companies participating in the study state that thanks to the definition of customer satisfaction as a key objective and the implementation of KPIs to track its implementation, they have established a significant increase in customer satisfaction: up to 20% - 4 companies; up to 35% - 6 companies; up to 50% - 6 companies; over 50% - 5 companies (Fig. 11).

Figure 11. Increase in customer satisfaction, in percentages
Source: author (2025)

Respondents in this study share their experiences with using and implementing KPIs in their management process and practices. As they explain when you start integrating KPIs into your business and production's operations, you gain a clear picture of the effectiveness of each individual indicator. This process allows you to determine which KPIs are delivering value and which indicators may require adjustments. And if a specific KPI does not provide sufficient or relevant information, it is a signal to consider replacing it with a more appropriate approach.

In a very short period of time, they reported serious improvement in several key areas of company management:

- marketing activities.
- innovations and investment policy.
- improved financial results and
- a positive impact on employees, regarding their motivation to achieve results, for development and career growth, as well as showing initiative and creativity in their work performance.

The benefits achieved as a result of implementing key performance indicators in the field of human resources are presented in the following graphs. Figure 12 shows the reported increase in personal motivation of employees when they were involved and committed to the current and operational goals of their enterprises and the linking of performance results to the achievement of these objectives.

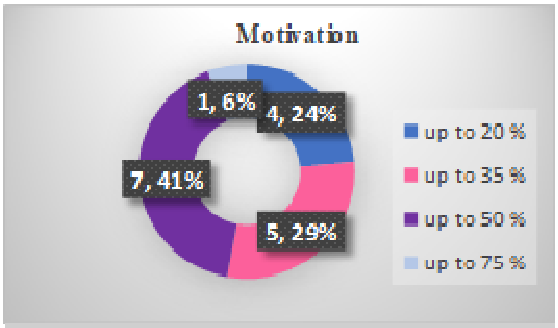

Figure 12. KPIs to increase motivation
Source: author (2025)

According to the results of the survey, an increase in personal motivation of up to 20% was observed in four enterprises; an increase of up to 35% was observed in five enterprises; an increase of up to 50% was reported by seven enterprises, and a more serious increase of up to 75% was found in only one enterprise (Fig. 12).

This positive effect is also observed when measuring employee initiative when they feel freer to present their ideas and views on improving processes, avoiding critical points, and making suggestions for improving the quality and products they produce. An increase in personal initiative of up to 20 % was reported by five enterprises; an increase of up to 35 % was observed in another 5 enterprises; an increase of up to 50 % was established by six enterprises; and only one enterprise reported an increase of over 75 % (Fig. 13).

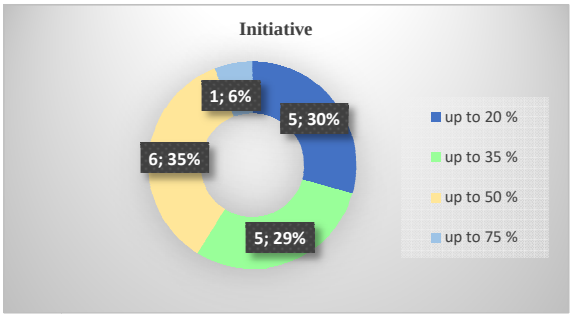

Figure 13. KPIs to increase initiative
Source: author (2025)

After the severe consequences of the Covid crisis and the serious loss of qualified workers and employees (according to some companies, around and over 50%), these companies are now reporting and enjoying an extremely positive trend among their staff. The opportunity to work in a high-tech and professional environment, producing quality and market-demanded products, encourages them to personal improvement, a desire to acquire new knowledge and skills, including a desire for development and career growth. Two companies reported up to 20% progress on this indicator. Six companies have established an increase of up to 35%. Up to 50% increase was registered in another six companies. And the result of three companies is remarkable, which declare up to 75% increase in the desire for development and growth of their workers and employees (Fig. 14).

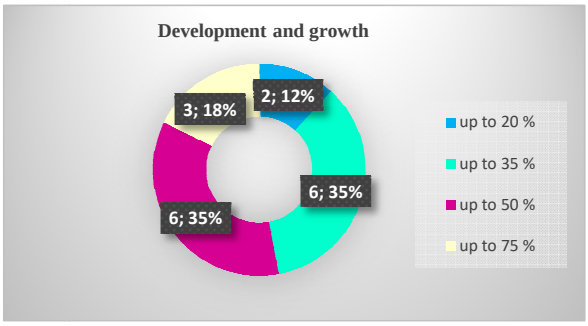

Figure 14. KPIs for development and growth
Source: author (2025)

By encouraging initiative and the desire for development in employees, the creative attitudes of the staff to find new solutions and approaches to fulfilling their work commitments are also unlocked. The staff willingly joins various work teams and initiatives to improve processes, brainstorming groups and other similar approaches in search of innovative and effective solutions to overcome emerging critical situations.

The results of the registered progress are shown in Figure 15 and are distributed as follows: progress of up to 20 % in promoting creative attitudes was reported by two enterprises; progress of up to 35 % was observed in six enterprises; an increase of up to 50 % was reported by seven enterprises; and progress of up to 75 % was reported by the remaining two enterprises participating in the study (Fig. 15).

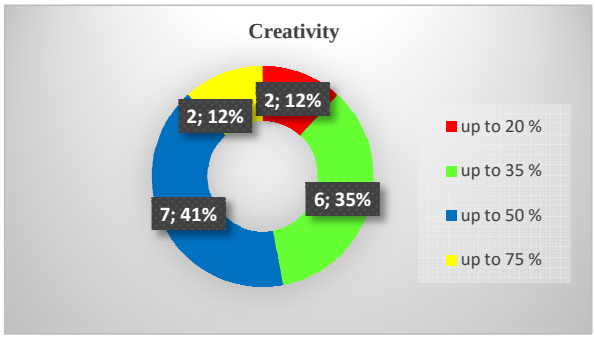

Figure 15. KPIs to increase creativity

4. Discussion

As we have already mentioned many times key performance indicators are available in all possible combinations and their diversity stems from the different goals and needs of both the industrial enterprise itself and the endless needs and demands of the customers that the organization is trying to satisfy. Key performance indicators are also distinguished by their complexity and size, since each of them serves to monitor a specific and specific goal in assessing the different aspects of the business and production's activities.

Thanks to the support of enterprises and their willingness to participate in this study, we had the opportunity to verify the usefulness and effectiveness of the use of key performance indicators through the application of various scientific methods and approaches to receive verification, evidences and practical results. As a result of this survey, we can make the following conclusions.

Conclusion

This study confirms the strategic importance of key performance indicators (KPIs) as a fundamental tool for enhancing organizational performance, aligning operational efforts with strategic goals, and supporting data-driven decision-making in industrial enterprises.

1. KPIs as a strategic management instrument:

The findings reinforce that KPIs are essential for measuring and tracking an organization’s progress toward its strategic objectives. They provide a multidimensional view of performance across departments and timeframes, allowing enterprises to benchmark their development against industry standards and peers. Particularly noteworthy is the relevance of the KPI “Market Share Growth”, which reflects a company’s competitive positioning. The empirical data show that eight of the surveyed enterprises achieved a market share increase of up to or above 50%, while thirteen reported growth between 20% and 35%. These results are especially significant in the context of recent macroeconomic disruptions, including the COVID-19 pandemic, global recession, and the geopolitical instability caused by the war in Ukraine.

2. Versatility and impact of KPIs across domains:

KPIs prove to be a highly adaptable instrument, applicable in various areas such as sales performance, customer satisfaction, employee productivity, and organizational innovation. Beyond monitoring, KPIs also promote motivation and accountability when properly communicated and integrated into the organizational culture.

3. Role of regular performance reporting:

Consistent and analytically grounded reporting transforms raw data into actionable insights. Through KPI monitoring, organizations can identify performance trends, anticipate operational bottlenecks, and uncover areas requiring immediate attention or long-term improvement strategies.

4. Facilitating transparency and stakeholder alignment:

Well-structured KPI reports, presented in clear and accessible formats, enhance communication across managerial levels. They support shared understanding of performance, foster cross-functional collaboration, and empower stakeholders to make timely and informed decisions.

Recommendations

Based on the findings of the study, the following practical recommendations are proposed:

- Expand the scope of KPI systems to include both lagging and leading indicators, integrating financial, operational, and behavioral metrics for a holistic view of performance.
- Enhance digitalization of KPI reporting by introducing automated dashboards and real-time analytics tools, particularly in medium-sized enterprises that lack advanced data infrastructure.
- Involve employees actively in the KPI design and evaluation process to foster ownership, motivation, and alignment with individual and team-level goals.
- Establish training programs focused on performance interpretation and data literacy, ensuring that decision-makers and operational staff can fully utilize KPI insights.

In conclusion, key performance indicators represent not only a measurement tool but also a strategic resource for building adaptive, resilient, and high-performing industrial organizations in today's complex and competitive environment.

Abstract

Research background: In the presented article, the author has made a theoretical study of issues related to business model management and the practical impact of digitalization on processes in manufacturing and industrial organizations. This significant impact in certain situations requires serious changes in the development and adaptation of appropriate business models to respond to the constantly changing business environment and to meet the growing needs of customers and consumers.
Purpose of the article: The purpose of this article is to prove the significant impact of digital transformation on the development of business models and to offer a practical model for transformation of business models in periods of crisis. Because the rapid development of digital technologies creates economic opportunities for innovation, growth and intellectual products. To ensure their success, organizations need to implement innovative business models and technologies.
Methods: To achieve the goal, the comparative analysis method was used, comparing the types and varieties of possible business models, on the basis of which the author developed own business model proposed in the article. The limitations in the study are reduced to the fact that the author himself sets the boundaries of his research and chooses only engineering and manufacturing organizations since business management is a vast scientific territory, and the volume of a scientific article is too short.
Findings & Value added: For every industrial organization, the choice of business model is of strategic importance, because in practice this is the way it does its business and generates added value. This means that every organization must implement solutions that support the development, testing and offering of new products and services based on digital technologies, including artificial intelligence. The implementation of digital technologies in modern industries are solutions that can provide competitive and sustainable advantages to any business organization. The author offers its own definition of the term "business model" and a model for transformation of business models in industrial organizations in periods of crisis.

Keywords: Business model, Digitalization, Impact of digital transformation, Industrial organization, Transformation of business model

JEL classification: M10, O20, O21

1. Introduction

Digital transformation of economy after Covid-19 crisis. The high-speed development in the digital field creates economic opportunities for innovation, growth, jobs and makes people's lives easier. The digital transformation is at the heart of the current industrial revolution and secures the future of business organizations. The digital transformation of the economy is a source of competitive advantage and creates conditions for prosperity in all areas. Business organizations must prioritize upgrading their strengths in advanced digital technologies and their strong presence in traditional sectors to take advantage of the opportunities offered by technologies such as 5G networks, robotics and artificial intelligence, 3D printing, and more. They could enable business organizations to gain a share of emerging markets for the products and services of the future. To ensure their success, organizations need to implement innovative business models and technologies. In practice, this means that every organization must implement

* Corresponding author: tszlateva@abv.bg

solutions that support the development, testing and experimentation of new products and services based on digital technologies, including artificial intelligence.

But almost five years ago, the Covid-19 crisis came suddenly, unexpected and changed the World. Nothing was the same - people and their believing, communications and partnerships, business models and economy. The rise in technologies that ushered in the new millennium and the prevailing principles of Industry 4.0, along with the digital transformation, seem to have given way to fear and paramount concern for the protection of human life. This situation has changed everything from the globalized heavy industrial markets to the smallest units in national economies - small businesses and private entrepreneurs. In addition to economic indicators, this crisis has hit industrial organizations hard in their most valuable and costly resource, human resources. This necessitated a change in the business models, strategies and policies of the manufacturing organizations. The development of flexible models and forms for dealing with the difficult situation and overcoming the crisis came to the fore. „To improve company's performance, it is essential to monitor and respond correctly to current trends that affect its business. Only then, the company can make a profit and meet the expectations of the owners and other interest groups." (Benkova et al., 2020)

The digital transformation is influencing business models by requiring the implementation of elements of Industry 4.0 related to technology transfer, construction of research and development centers of a new type such as science and technology parks and the creation of electronic networks for cooperation, trade and training. To achieve this, it is necessary to apply information and communication technologies in related cyber-physical systems and create integrated business models.

The positive impact of the digital transformation on industrial production and modern manufacturing organizations can be expressed in the creation of new products and services with built-in intelligence that would fully meet customer requirements and develop innovative business models; digitalization and flexible organization of production processes, development of digital prototypes and virtual production (figure 1).

Literature review

1.1 The impact of digitalization on business model's transformation.

In recent years, there has been a lot of talk about the digital transformation and the penetration of digital technologies in all spheres of public and economic life. These topics are the subject of many scientific studies and are worked on by both famous scientists and practitioners. Governments develop strategies and concepts for business digitalization, measures and programs for innovation, jobs, growth, and improving societal standards. So, let's take a brief look at the work of some scientists and how they define the digital transformation of business.

Digital transformation is the reorganization of business by changing the business strategy or digital strategy, models, operations, products, marketing approaches, goals and more. through the acquisition of digital technologies. This accelerates sales and overall business growth. (Stolterman et al., 2004)

Digital business transformation is a process of rediscovering business to digitize operations and formulate expanded supply chain links. The challenge for digital business transformation management is about reengineering the business, which can now successfully capture the full potential of information technology throughout the supply chain. (Bowersox et al., 2005)

Digital transformation is a conscious and ongoing digital evolution of a company, business model, conceptual process or methodology, both strategically and tactically. (Mazzone, 2014)

Digital business transformation - significant changes in organizational processes, structures and systems applied to improve the productivity of organizations through the use of more and more digital media and technology platforms. (Chaffey, 2015)

Digital Business Transformation is Organizational Change through the use of Digital Technologies and Business Models to Improve Performance. (Wade, 2015)

The rapid penetration of digital technologies in business imposes the need for digital transformation of modern organizations. It includes all activities related to the application of digital technologies. Digital transformation facilitates business processes, decision-making and interaction with value chain partners and end customers. (Slavova, 2015)

The digital transformation of business is an objective process that corresponds to the changing business environment. Its implementation requires a clear strategy and prioritization, supported by financial resources, leadership and active participation of all employees in the organization. The speed of its flow depends on the specifics of the sector. (Slavova, 2016)

The digital transformation includes in its framework the building of contacts between business representatives and consumers through all segments of the value chain and the application of new technologies. In itself, digital transformation requires skills such as retrieving and exchanging data, as well as analyzing and converting that data into information for future action. This information should be used to calculate and assess probabilities to enable decision-making and/or initiation of activities. To increase company productivity and impact, digital transformation includes organizations, business models, processes, relationships, products, and more. (Schallmo et al., 2017)

Generally speaking, digital transformation is the integration of new digital technologies in all areas of business, leading to a fundamental change in the way the organization works. (Shopov, 2017)

Digital business transformation is a process that takes place in enterprises to meet changing needs through the implementation and use of innovative and integrated technologies, creating the need for new management approaches, processes and skills, both managers and contractors. (Boneva, 2018)

Digital transformation marks a rethinking of how an organization uses technology, people, and processes in pursuit of new business models and new revenue streams, driven by changes in customer expectations around products and services. (Boulton, 2021)

1.2 What is a business model?

Business models are a management tool that describes recurring problems for a group of organizations and provides a solution to these problems based on good practices in other organizations and companies.

Let us briefly recall what the business model is in order to look for opportunities for its transformation in the conditions of crisis and accelerated digitalization of technologies. There are too many definitions of different authors in scientific literature. This is because scientists have studied different types of companies and organizations and have been guided by different criteria in their research.

At a general level, the business model has been referred to as a statement (Stewart&Zhao, 2000), a representation (Morris, Schindehutte &Allen, 2005; Shafer, Smith&Linder, 2005), an architecture (Timmers, 1998), a structural template (Amit&Zott, 2001), and a set (Seelos&Mair, 2007). Surprisingly, however, the business model is often studied without an explicit definition of the concept.

"… a successful business model represents a better way than the existing alternatives. It may offer more value to a discrete group of customers. Or it may completely replace the old way of doing things and become the standard for the next generation of entrepreneurs to beat. Creating a business model is, then, a lot like writing a new story. At some level, all new stories are variations on old ones, reworkings of the universal themes underlying all human experience. Similarly, all new business models are variations on the generic value chain underlying all businesses. Business modeling is the managerial

equivalent of the scientific method—you start with a hypothesis, which you then test in action and revise when necessary." (Magretta, 2002)

"the functions of a business model are to: articulate the value proposition, identify a market segment, define the structure of the value chain, estimate the cost structure and profit potential, describe the position of the firm within the value network, and formulate the competitive strategy." (Chesbrough and Rosenbloon, 2002)

"The logic of the firm, the way it operates and how it creates value for its stakeholders." (Lecocq et al., 2006):

Johnson and Kagermann determined the four elements of business models: a customer value proposition, a profit formula, key resources, and key processes. (Johnson and Kagermann, 2008)

Business model design involves assessments with respect to determining: (1) the identity of market segments to be targeted; (2) the benefit the enterprise will deliver to the customer; (3) the technologies and features that are to be embedded in the product and service; (4) how the revenue and cost structure of a business is to be 'designed' (and, if necessary, 'redesigned') to meet customer needs; (5) the way in which technologies are to be assembled and offered to the customer; and (6) the mechanisms and manner by which value is to be captured, and competitive advantage sustained. These issues are all interrelated. They lie at the core of the fundamental question asked by business strategists – which is how does one build a sustainable competitive advantage. (Teece, 2009)

Based on this existing theoretical basis, the Author offers his own definition of a business model, which focuses mainly on the functional side of business models and brings to the fore the practical benefits of implementing business processes. This definition refers to industrial business models with a real production process, which the Author presents as a transformational process (Figure 1).

Author`s definition for the term "business model" (Figure 2): The way of organizing and managing business processes and resources (material, financial and human) in order to meet customers demand, create added value and profit to ensure the future development of the industrial organization and its prosperity.

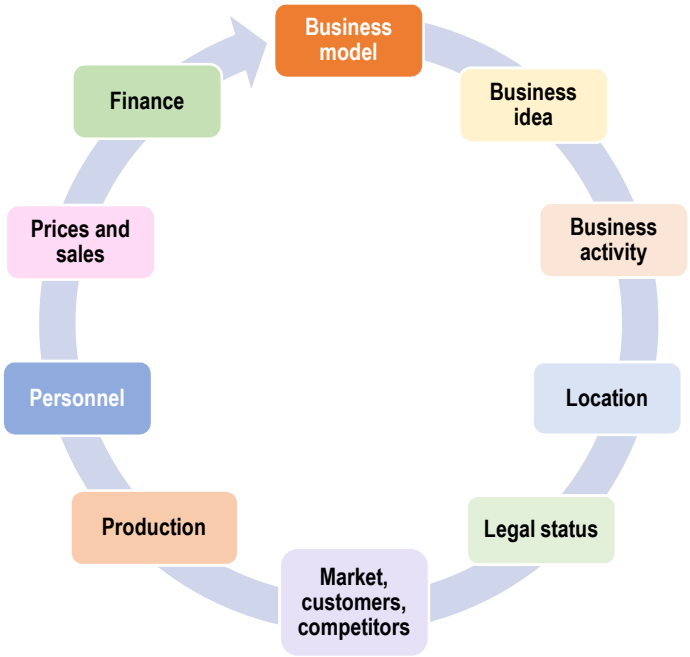

Figure 2. Process for generating and operating a business model
Source: Author (2025)

2. Methods

The purpose of this article is to prove the significant impact of digital transformation on the development of business models. For any organization, the choice of business model is of strategic importance, because in practice this is the way it does its business and generates added value.

To achieve the goal, the comparative analysis method was used, comparing the types and varieties of possible business models, on the basis of which the author developed and proposed in this article his own definition of the term "business model".

Also, the methodology of system-structural analysis was used, which creates the opportunity to consider related processes and phenomena as a structured system that functions at the level of the manufacturing enterprise and allows the Author to create and propose in this article his own business model for industrial organizations.

The limitations in the study are reduced to the fact that the author himself sets the boundaries of his research and chooses only engineering and manufacturing organizations since business management is a vast scientific territory, and the volume of a scientific article is too short.

The topic is well known and still relevant because business processes and their management is a daily activity for management specialists, but unfortunately there is still much to add and improve in the knowledge, skills and competencies of managers. Overall, the author believes that this is a topic that would help to achieve higher goals and results, and to improve the existing management practice.

3. Results

What and why should it be transformed in business models? Today, digitalization is seen as a megatrend to achieve new levels of productivity. Virtual and real worlds are getting closer than ever and lead to "Industry 4.0". Production operations are combined with the latest information and communication technologies, and the driving force behind this development is the rapid digitalization of the business world and society as a whole.

The implementation of the digital transformation of business models implies an organizational change that can be realized through the use of digital technologies and models to improve the final financial and production results, as well as labor productivity.

In the context of digital transformation, consumers are the engine of change. The process of digital transformation must be carried out jointly with customers and for their benefit through targeted introduction of new models, solutions and applications for inclusion and development of human potential based on building a digital culture and thinking to achieve concrete results and enrich the life of citizens [30]. Technology is a tool, not a goal in digital transformation. The implementation of modern technologies with simple solutions is the ideal combination that will make economy intelligent, competitive and sustainable.

The consulting company Gartner applies a detailed list of actions in the presence of threats (Gartner, 2020):

1. Reassessment of the business model, paying priority attention to several main parts of the business model:
   - Consumer segments and how they are affected by the crisis.
   - What changes occur in the value supplied to consumers, do they already have other needs.
   - Whether the organization can offer the required value.
   - What the organization needs to do it herself.
2. Identification of unknown quantities and determination of probable scenarios for occurrence. As difficult as this may be, at least the main variables can be outlined in an optimistic and pessimistic version.
3. Business impact analysis, forecasting the consequences of the crisis and developing recovery strategies.

How can we change the business model? The change in business models requires a serious process of transformation, which begins with a rethinking of the existing situation and leads to a reorganization of the practices that the organization applies.

The Author proposes a possible model in eleven main steps for the transformation of a business model caused by a crisis in the industrial business environment (figure 3).

Step 1. Defining and, if necessary, redefining the goals – identifying the core values and mission of the business.
Step 2. Identifying the risks and the most significant trends of change in the business environment.
Step 3. Assessing the damage and losses caused by the crisis.
Step 4. Analyzing the activities and processes within the organization.
Step 5. Analyzing the necessary resources and possibilities for their provision.

Step 6. Identifying potential business partners.
Step 7. Creating additional opportunities.
Step 8. Searching for approaches, methods, and tools for change; developing possible options.
Step 9. Developing an example model that focuses on the most important or critical points.
Step 10. Maintaining a high level of motivation - inspiration through innovative models that ensure long-term competitiveness and sustainability.
Step 11. Evaluating the achieved result.

Figure 3. Model for transformation of a business model
Source: Author (2025)

4. Discussion

For any organization, the business model is of strategic importance because it reflects the way the organization carries out its business processes. Regardless of the scale of the business or industry in which the organization operates, the business model illustrates how the organization designs and manufactures products or how it provides services to its customers. Business models describe and manage specific business processes; build and provide appropriate infrastructure; develop competitive strategies for expanding market presence and entering new markets.

The rapid development of digital technologies and the difficult epidemiological situation around the world have necessitated the rapid penetration of digitalization in the ways of doing business. The inevitable closure of many businesses and markets due to lockdowns has increased Internet influence in all areas - trade, banks, education, administrative services and much more. This imposed certain business models as more successful and up-to-date. The models for direct sales, franchising, freemium, subscription and crowdsourcing became such models.

Direct sales. Business models that rely on direct sales prefer to stay in touch with their customers. To this end, they develop a distribution network or center where individual retailers contact the parent company to offer their products or services at retail. In this way, these traders become entrepreneurs and make a direct connection with the consumers of the good or service. This gives them the opportunity to receive first-hand information about the evaluation and customer satisfaction of the product or service, as well as to get ideas for their improvement or updating. Customers could also share information about their experience using a similar product offered by the organization's key competitors.

Direct sales can be made through presentations or demonstrations of the product or service in several different situations, such as organizing a presentation of a new product, organizing a party at home and presenting the products to guests or presenting the business to potential customers and investors.

In direct sales, traders profit by receiving part of the sales revenue or a certain percentage, and the parent company generates the sales revenue.

Some of our best known companies that follow the business model of direct sales are Avon, Arbonne and Herbalife.

Franchising. Franchising is, in fact, a strategic alliance between organizations, one of which has an established image and offers a prestigious brand under certain conditions and for a fee to another organization that wants to develop the same activity and gets the right to use a developed and successful business model in a certain kind of business. The following types of Franchising are known: production - for the production of goods, using the provided production experience, know-how, brands and others; placement - for distribution of goods or services; and franchising services.

This cooperation is successful and beneficial for both parties, because the franchisee does not have to invest capital in developing their own products and brands, and the franchisor gets access to a large number of users without having to incur costs to enter new markets or expand its distribution network.

Freemium model. The freemium model is typical when private or business services are offered mainly from the Internet. This model enables organizations to connect with their future customers and lay the foundation for a good collaboration. Initially, organizations provide free basic services. After building trust with their customers, they offer to expand the services, add applications or use the same services, but without including ads, thus improving the user experience for a fee.

This model works successfully for Internet organizations that do not want to make serious investments to acquire new customers, but at the same time offer high value to their users.

Examples of well-known companies working on the freemium business model are Spotify and Skype.

Subscription model. When organizations are forced to pay high costs for expanding markets and gaining new customers, they need to secure a circle of secure customers to ensure periodic sales revenue. This can be achieved through the subscription model, which provides a set of customers under a long-term contract and multiple consumption of the product or service, which allows to form a relatively stable sales revenue.

This model is used by business organizations that provide utilities, telephone companies, Internet providers, mobile and electronic services.

Crowdsourcing. This practice is about getting the services, ideas, or products you need by attracting a large group of people. In most cases, these users are organized online. Projects are usually announced publicly and anyone can volunteer.

Crowdsourcing is indeed the process of combining the efforts of a large, diverse group of people to achieve a common goal, where each individual contributes their unique skills, knowledge, or resources. It's essentially outsourcing a task, idea, or content generation to a broad, often online, community. This collaborative approach allows for the gathering of diverse perspectives, potentially leading to innovative solutions and efficient outcomes. The contracting company usually announces a prize that is linked to the outcome of the project. Sometimes it is a monetary payment, and in other cases the group of people may work due to moral motives (personal satisfaction, honor, fame).

The practice is often applied on the Internet, when a solution to a problem is sought by the users of a certain site, product or service.

There are an infinite number of examples and good practices for transforming business models as a result of the increased digitalization of business processes in industrial enterprises. It is extremely positive and encouraging that this trend is happening all over the world, and not only in developed regions or advanced economic countries. Due to the limitations of the scope of this article, the author has selected only a few different and diverse examples and good practices to demonstrate the true diversity of business model transformations:

- "Recently, Briones Peñalver and Prokopchuk (2023) analyzed the adaptation of drinking water business models to the blue economy in Ukraine."
- "A new approach to installing rubber mats in dairy farms was proposed by Chanthes et al. (2024) and demonstrated significant productivity gains."
- "Chemerys et al. (2019) show how business model development in rural Ukraine can stimulate sustainable growth."
- "Dyadyuk (2016) proposes improving methodological principles for managing competitiveness in crises."
- "Sumets (2018) examines business management strategies, and later (2020) proposes a methodological approach for assessing production systems."
- "A study by Widadie et al. (2024) demonstrates models for integrating smallholder farmers into high-value vegetable markets."
- "Zott, Amit and Massa (2011) summarize recent developments in business models research and outline key directions for future research."
- "Bogdanova (2020) analyzes university business models in times of crisis."

Conclusion

If it is possible to find anything positive in the emergency and pandemic situation and the Covid-19 crisis, it is to accelerate the process of digital transformation. In isolation, many companies had to close offices, production facilities and work remotely, in an electronic environment. Business organizations orientated themselves quickly and flexibly and began to make the most of the opportunities and potential of digital technologies in all sectors of the economy, social activities and politics, education, medicine and others. This proved once again the key importance of the digital transformation and confirmed the fact that it is not just a necessity, but a prerequisite for competitiveness and sustainability of business models and processes in a crisis. Thanks to digital technologies, many companies have survived the crisis, kept their markets, their associates and continue to grow. Others, who were more enterprising, created new business models, new jobs, and new revenue opportunities for e-services.

The rapid development of digital technologies creates economic opportunities for innovation, growth and intellectual products. To ensure their success, manufacturing organizations need to implement innovative business models and technologies. In practice, this means that every organization must implement solutions that support the development, testing and offering of new products and services based on digital technologies, including artificial intelligence. The implementation of digital technologies in modern industries are solutions that can provide competitive and sustainable advantages to any business organization. The impact of digital transformation on business models is so significant because it replaces a huge range of physical offerings with digital tools and services. In their desire to reach more customers and consumers, organizations offer and introduce digital products and require the use of technologies to provide global shared services. Thanks to the digital transformation, industrial organizations adapt more easily than ever to the ever-changing conditions of the business environment and are eager to improve and refine their performance in order to achieve higher efficiency, meet the requirements for products/services and improve of the end-user experience.

Business models are available in a variety of forms. The article is intended for managers in practice who need to adapt their business models to the ever-changing environment and the growing needs of consumers. For business administration specialists, this article can be an additional look at the current situation and expand their knowledge of business models. The process of organizational change through the use of digital technologies and new business models to improve economic performance in response to changing consumer behavior is inevitable for industrial organizations in the current digital economy and the so-called fourth industrial revolution.

3. Business and Marketing

A Gender Perspective on Selected Neuromarketing Attributes to Enhance Sales

***Zuzana* Birknerova**[1] **and *Lucia* Zbihlejova**[2,*]

[1] University of Prešov in Prešov, Department of Managerial Psychology, Faculty of Management and Business, Konštantínova 16, 080 01 Prešov, Slovakia
[2] University of Prešov in Prešov, Department of Intercultural Communication, Faculty of Management and Business, Konštantínova 16, 080 01 Prešov, Slovakia

Abstract

Research background: Neuromarketing, as an intersection of psychology, neurology, and marketing, is concerned with the study of how neuromotor and emotional responses influence consumer decision-making. Gender differences in these responses can have a significant impact on the creation of marketing strategies, and recognizing these differences can help marketers create more effective and precisely targeted campaigns.
Purpose of the article: The main objective of this study is to examine cognitive, emotional, and behavioral factors in sales neuromarketing and, subsequently, gender differences in the assessment of these factors or attributes that influence consumer decision-making. Part of this objective is to present how findings from neuromarketing research can contribute to optimizing consumer behavior to enhance sales success.
Methods: The initial survey and subsequent research were conducted on a sample of 122 respondents who evaluated individual attributes through the NMCEB methodology. Furthermore, a hypothesis that neuromarketing approaches integrating these attributes lead to more effective influence on consumer behavior and subsequently to increased sales compared to traditional approaches was tested.
Findings & Value added: The results showed that women are more affected by emotional stimuli than men, with statistically significant differences in emotional reactions during purchasing decisions. These findings emphasize the need to customize marketing strategies according to gender differences to enhance their effectiveness and efficiency.

Keywords: Neuromarketing, Gender differences, NMCEB methodology, Sales

JEL classification: M31, D91, J16

1. Introduction to Neuromarketing

Neuromarketing is an interdisciplinary field that combines knowledge from neuroscience, psychology and marketing to better understand how consumers perceive and respond to various marketing stimuli, such as advertisements, products or brands. Morin (2011) presents neuromarketing as a new science of consumer behavior. He emphasizes how neuromarketing techniques can reveal hidden motivations and reactions of consumers to marketing stimuli and incentives. Kenning, Linzmajer (2011), Balconi and Sansone (2021) provide an overview of the development of consumer neuroscience and discuss its benefits and potential risks, including consumer protection. In recent years, neuromarketing has established itself as an important tool for obtaining deeper and more accurate knowledge about how consumers respond to various marketing stimuli (Lee, Broderick & Chamberlain, 2007).

Neuromarketing focuses on investigating consumers' neural responses to marketing stimuli using techniques such as functional magnetic resonance imaging (fMRI), electroencephalography (EEG), and eye-tracking (Alsharif et al., 2023). These techniques allow researchers to analyze how various stimuli, such as advertisements, product packaging, or pricing policies affect consumers' brain activity and emotional responses (Plassmann, Ramsøy & Milosavljevic, 2012). Neuromarketing techniques such as

* Corresponding author: lucia.zbihlejova@unipo.sk

fMRI, EEG, and biometric methods allow scientists to track consumers' brain responses and physiological responses to marketing stimuli. These techniques provide deeper insight into cognitive and emotional processes that traditional marketing methods cannot effectively map. Ariely (2008) examines how irrational behavior influences consumer decision-making. The author shows how small changes in product presentation can significantly influence consumer decisions, which has direct implications for neuromarketing. Ariely, Berns (2010), Ismajli, Ziberi, and Metushi (2022) provide an overview of the possibilities and limitations of neuromarketing, including a discussion of how neuroimaging can help understand consumer preferences.

One of the main applications of neuromarketing is the optimization of marketing campaigns. Analysis of neuromarketing data can reveal which aspects of marketing materials, such as visual elements, sound effects, or text, most influence consumers' attention and emotional responses (Gerdes et al., 2021). For example, studies have shown that emotionally resonant advertisements tend to create stronger memory traces and higher levels of engagement (Rigby & Lee, 2024). Neuromarketing also provides valuable information about how consumers evaluate products and brands. Techniques such as eye-tracking can reveal which parts of packaging or advertising attract the most attention and which elements may influence purchase decisions (Wedel & Pieters, 2007). In addition, EEG analysis can provide insight into consumers' emotional responses to various marketing stimuli, allowing marketers to tailor their strategies to better resonate with their target audience (Alsharif & Isa, 2025).

Neuromarketing is an invaluable tool in the study of consumer behavior because it provides objective data on how consumers respond to various marketing stimuli at the neurobiological level (Alsharif & Isa, 2025). This knowledge can be used to create more effective marketing strategies and improve the overall consumer experience (Panksepp, 1998). With the advent of new technologies and analytical methods, the importance of neuromarketing in consumer behavior research is expected to continue to grow, allowing for even more precise tailoring of marketing activities to consumers' needs and preferences.

Therefore, the main objective of the presented study is to examine cognitive, emotional, and behavioral factors in sales neuromarketing, as well as gender differences in the assessment of these factors as they influence consumer decision-making, and present how findings from neuromarketing research can contribute to optimizing consumer behavior to enhance sales success.

2. Cognitive, Emotional, and Behavioral Factors in Sales Neuromarketing

One of the key aspects of neuromarketing is the study of cognitive and emotional factors that influence consumer decision-making. Kahneman (2011) discusses two systems of human thought – fast, intuitive thinking and slow, rational thinking. He provides a deep insight into the cognitive processes that influence consumer behavior and decision-making. Emotions play a fundamental role in shaping consumer preferences and decisions. Neuromarketing findings show that the emotional resonance of an advertisement or product can significantly influence not only short-term purchase decisions, but also long-term brand loyalty. Behavioral economics and neuromarketing together examine how various stimuli and environments influence consumer behavior (Cenizo, 2025). Factors such as product design, store shelf layout, and visual and audio cues can have a significant impact on purchasing decisions. Studies show that changing the presentation of a product can increase the likelihood of purchase. Neuromarketing techniques help uncover these subtle differences and enable marketers to create more effective campaigns and strategies. Lindstrom (2010) examines the subconscious factors that influence purchasing decisions and offers practical examples of how marketers can use neuromarketing insights to improve marketing campaigns.

One example is the "nudge theory" popularized by Thaler and Sunstein (2008). This theory suggests that subtle changes in the environment in which a consumer finds themselves can significantly influence their behavior. Neuromarketing techniques provide a better understanding of how these subtle changes can improve the effectiveness of marketing campaigns and increase sales. These techniques also help to reveal consumers' subconscious responses to various stimuli and provide marketers with valuable information for optimizing their strategies, which is especially effective in optimizing marketing campaigns. Kahneman (2011) describes in detail concepts such as "anchoring" and the "availability heuristic", which are part of the cognitive biases that influence consumer decision-making. Behavioral factors also include the concept of "behavioral biases", i.e. cognitive biases that can influence consumer decision-making. These biases can lead consumers to make unanticipated decisions that traditional marketing approaches often fail to take into account.

Neuromarketing research shows that understanding these biases and implementing them into marketing strategies can lead to increased sales and more effective influence on consumer behavior (Cenizo, 2025). Integrating neuromarketing insights into marketing strategies presents a great opportunity for marketers. Neuromarketing provides specific recommendations for optimizing ad content, website design, and product placement to better resonate with target customers. The key is to consider cognitive, emotional, and behavioral factors that can lead to increased sales. Marketers who can apply this insight can better target their campaigns and achieve higher returns on investment. Plassmann, Ramsøy and Milosavljevic (2012) provide a critical overview of neuromarketing, describing the current state of neuromarketing research and its applications in the areas of branding and consumer decision-making. They discuss how neuromarketing methods help to better understand how brands influence consumer behavior.

3. Gender Differences in Responses to Neuromarketing Stimuli for Marketing Strategies

As mentioned above, neuromarketing, as an intersection of psychology, neurology, and marketing, is concerned with the study of how neuromotor and emotional responses influence consumer decision-making. Gender differences in these responses can have a major impact on the creation of marketing strategies, as different genders may respond differently to the same marketing stimuli (Suh, Wilson & On, 2023). Recognizing these differences can help marketers create more effective and precisely targeted campaigns. Gender differences in responses to marketing stimuli can be analyzed through various neuromarketing techniques (Stefko et al., 2021). Functional magnetic resonance imaging (fMRI) and electroencephalography (EEG) allow researchers to examine how male and female brains respond to different types of stimuli, such as visual advertisements, audio cues, or text messages (Alsharif & Isa, 2025). These techniques provide data on which brain areas are activated in response to marketing stimuli and how these responses influence the final purchase decision (Plassmann, Ramsøy & Milosavljevic, 2012).

3.1 Gender Differences in Cognitive Responses

Cognitive responses to marketing stimuli can vary considerably in the context of gender. For example, women may be more sensitive to the visual and emotional elements of advertisements, while men may be more responsive to the rational and functional aspects of products (Putrevu, Tan & Lord, 2004). This distinction may influence how marketers tailor their campaigns to suit different preferences and values, which may lead to more effective marketing strategies.

3.2 Gender Differences in Emotional Responses

Emotional responses to marketing stimuli may also exhibit gender differences. Women often show stronger emotional responses to advertisements that contain emotional content or social elements such as family and friendship (Majeed, Lu & Usman, 2017). Conversely, men may be more influenced by advertisements that emphasize performance or technical features of products (Sheehan, 2013). These differences in emotional responses can be used to design marketing campaigns that are more gender-specific.

3.3 Gender Differences in Behavioral Responses

Behavioral responses to marketing stimuli may also differ between men and women. Men and women may respond differently to interactive stimuli, such as product tastings or physical contact with the product (Lidón et al., 2018). Women may be more likely to seek out and respond to the opportunity to physically explore products, while men may place greater emphasis on practical aspects and product performance (Wedel & Pieters, 2007).

4. Methodology

In terms of methodology, the paper contains two studies. The first one is a preliminary survey carried out in two stages – secondary data analysis and questionnaire analysis – to assess how the implementation of neuromarketing improves consumer behavior and increases sales. The second study consists of research the aim of which is to determine whether there are statistically significant gender differences in the assessment of the selected neuromarketing attributes.

For the purposes of the research, the NMCEB methodology (Birknerová, Miško & Ondrijová, 2022) was used to assess the cognitive, emotional and behavioral aspects of neuromarketing. The questionnaire contains 15 statements that respondents assess on a Likert scale of agreement from 1 – "definitely no" to 6 – "definitely yes".

The three NMCEB factors may be specified as follows:

Cognition: Cognitive attributes focus on perception, cognition and information processing. Items in this category examine how customers acquire and process information about products through various sensory stimuli: Music can improve cognitive information processing by improving attention and memory. Tactile perception (touch) increases customer trust and perception of quality, which affects decision-making. Olfactory perception contributes to product evaluation, especially for items such as food or cosmetics. Taste as a cognitive factor provides direct information about the quality and method of use of the product. Reading the composition and description of a product allows customers to make informed decisions.

Emotions: Emotional attributes focus on how sensory stimuli evoke positive or negative emotions in the customer: Music in a store can create an atmosphere that promotes positive feelings and increases satisfaction. Touch can lead to an emotional attachment to a product, which increases the chances of a purchase. Smell can evoke pleasant memories and improve mood, which positively affects purchasing behavior. Tasting a product can lead to emotional satisfaction, which supports the decision to purchase. The visuals and design of the packaging can directly affect the emotional response and attractiveness of a product.

Behavior: Behavioral attributes examine how these stimuli influence real-world purchasing decisions and behavior: Identification with music can subconsciously influence movement in a store and purchasing decisions. Touch affects not only cognitive perception, but also decision-making and final purchasing behavior. Olfactory sensations can lead to increased time spent in the store and a greater likelihood of purchase. Tasting a product can directly lead to impulse purchase. Packaging design and presentation can have a major impact on a customer's final decision.

The research sample consisted of a total of 122 respondents, of which 46 were male (37.7%) and 76 were female (62.3%). In terms of completed education, we addressed 35 (28.7%) respondents with secondary education, 38 (31.1%) with a first-level university education, 47 (38.5%) with a second-level university education and 2 (1.6%) with a third-level university education.

5. Preliminary Survey

The aim of the initial survey is to verify how the implementation of neuromarketing improves consumer behavior and increases sales. It focuses on identifying specific neuromarketing techniques that have the greatest impact on the cognitive, emotional and behavioral aspects of consumer decision-making, and their potential for optimizing marketing strategies in various industries. The survey was based on a combination of a systematic literature review and a questionnaire survey among experts in the field of neuromarketing and marketing. The systematic literature review was carried out by analyzing academic databases such as Google Scholar, PubMed and ScienceDirect. The studies were categorized according to the neuromarketing techniques used and the results analyzed, focusing on identifying the main trends and applications within these studies.

5.1 First stage of the survey: Secondary data analysis

The first phase of the research involved a thorough analysis of existing academic studies and professional articles in the field of neuromarketing. This analysis focused on identifying the most commonly used neuromarketing techniques, such as eye-tracking, EEG and fMRI, and on examining case studies that document the successful use of neuromarketing in practice and its benefits for increasing sales. The results of this analysis provided a basis for understanding current trends and identifying areas where neuromarketing brings the greatest added value. To complement the systematic review of the literature and case studies, a quantitative analysis of secondary data was conducted. This analysis focused on statistical data on sales, the success of marketing campaigns and consumer behavior before and after the implementation of neuromarketing techniques.

Secondary data was obtained from publicly available databases, company annual reports and market surveys. The analysis of this data allowed for a quantitative comparison of the impact of neuromarketing approaches on sales and consumer behavior compared to traditional methods. The statistical methods used

included correlation analysis, regression analysis, and other methods to measure the effectiveness of marketing strategies. Although the systematic literature review and case study analysis provide valuable insights, the study faced several limitations. The main challenges included the limited availability of some empirical data and differences in the methodologies used in the analyzed studies. In addition, the quantitative analysis was limited by the availability of secondary data that could provide a more comprehensive picture of the long-term impact of neuromarketing.

5.2 Second stage of the survey: Questionnaire analysis

The second stage of the survey was conducted by means of a questionnaire survey among experts in the fields of marketing, neuromarketing and business. The questionnaire included questions focused on the perception of the effectiveness of neuromarketing techniques in optimizing marketing campaigns and consumer behavior, experiences with the use of these techniques and their impact on campaign results, identification of the most effective techniques that contributed to improving consumer behavior and increasing sales, and suggestions for better use of neuromarketing knowledge in marketing strategies. The data obtained were analyzed using frequency statistical methods to determine the extent to which neuromarketing techniques translate into improved marketing results.

Based on the analysis of selected studies, several key areas were identified where neuromarketing techniques have demonstrated a significant impact on consumer behavior and sales success. The most prominent techniques include eye tracking, which allows us to understand which parts of an advertisement or product consumers are most focused on, and electroencephalography (EEG), which measures consumers' emotional and cognitive responses to various marketing stimuli. The research confirmed that neuromarketing approaches that integrate cognitive, emotional, and behavioral factors lead to more effective influence on consumer behavior and, consequently, to increased sales. Experts who participated in the questionnaire survey agreed that neuromarketing techniques that focus on emotional resonance and understanding consumers' subconscious responses are the most effective in optimizing marketing campaigns and increasing sales.

6. Research

Following the outcomes of the preliminary survey, the aim of the research was to determine whether there are statistically significant gender differences in the assessment of neuromarketing attributes according to the NMCEB methodology (NeuroMarketing – Cognition, Emotion, Behavior). For this purpose, the following hypothesis was formulated:

"There are statistically significant gender-based differences in the assessment of selected neuromarketing attributes (cognitive, emotional, behavioral reactions)."

6.1 Analysis of gender differences in the assessment of neuromarketing attributes

The research focused on the analysis of gender differences in the assessment of neuromarketing attributes. Based on the results of the data distribution normality testing (Table 1) it is possible to consider the use of parametric statistics.

Table 1. Data distribution of NMCEB methodology attributes

	Cognition	**Emotions**	**Behavior**
N	122	122	122
Skewness	-.191	-.335	-.256
Curtosis	-.279	.116	-.195

Source: own processing

The results of the normality test show negative skewness values within the neuromarketing attributes of Cognition, Emotion and Behavior, which indicates that respondents indicated more larger values than smaller ones in their answers. The hypothesis: "There are statistically significant gender-based differences in the assessment of selected neuromarketing attributes (cognitive, emotional, behavioral reactions)" was analyzed using a t-test for two independent samples in the statistical program IBM SPSS Statistics 26. Table 2 describes the gender differences recorded.

Table 2. Statistically significant gender-based differences in the selected neuromarketing attributes assessment

Attribute	Gender	M	t	Sig.
Cognition	male	4.4125	1.113	.270
	female	4.6207		
Emotions	male	4.2000	2.969	**.004**
	female	**4.7655**		
Behavior	male	4.5375	1.104	0.274
	female	4.7655		

Source: own processing

The results of the t-test confirmed the existence of statistically significant differences in emotional reactions between the male and female respondents. Females show higher scores in emotional reactions when evaluating neuromarketing stimuli (mean 4.7655, $t = 2.969$; $p < 0.004$) compared to males. This result indicates that females are more influenced by emotional stimuli in purchasing decisions than males, who tend to make decisions based on practical and rational factors. Based on these results, it is possible to regard the ***hypothesis*** that there are statistically significant gender-based differences in the assessment of selected neuromarketing attributes as ***supported***.

7. Discussion

The results of a preliminary study in the form of a systematic literature review suggest that neuromarketing techniques have significant potential to optimize consumer behavior and increase sales. The findings show that the integration of cognitive, emotional, and behavioral factors allows for a better understanding of how consumers perceive and respond to various marketing stimuli. These techniques allow marketers to create campaigns that are not only more effective, but also better targeted at specific market segments. One of the key findings is that emotionally charged advertisements and products tend to resonate more deeply with consumers, leading to higher levels of recall and brand loyalty. Emotions have been shown to be a key factor in purchasing decisions, often outweighing rational considerations. This aspect is extremely important for marketers who are trying to create a strong emotional bond between the brand and the consumer. Another important factor is the behavioral optimization of the sales environment. Research shows that even small changes in packaging design, product layout, or store atmosphere can lead to significant changes in consumer behavior. For example, studies that investigated the impact of music, lighting, and scent on purchasing decisions have shown that these elements can subconsciously influence customers and increase the likelihood of purchasing.

According to the results of the research study, the NMCEB methodology provides a comprehensive view of how various sensory stimuli and factors influence consumer behavior from a cognitive, emotional, and behavioral perspective. The results of this research show that consumers' cognitive, emotional, and behavioral responses to neuromarketing stimuli vary not only individually but also by gender. The findings indicate that females tend to be more sensitive to emotional stimuli, which can affect their purchasing behavior more significantly than males.

These gender differences are of fundamental importance to marketing practice, as they allow marketers to create campaigns that are tailored to the specific needs and preferences of different gender groups. Personalizing marketing strategies based on these differences can significantly increase the effectiveness of campaigns while improving consumer experience. In addition, understanding the interactions between cognitive, emotional, and behavioral factors can help design more comprehensive and effective marketing strategies (Alsharif & Isa, 2025; Plassmann, Ramsøy & Milosavljevic, 2012). Implementing neuromarketing findings into practice also brings new challenges, such as using these techniques ethically and ensuring that consumers are not being manipulated unconsciously. This aspect is particularly important because neuromarketing taps into subconscious processes that are beyond the conscious control of consumers. Therefore, it is essential that marketers use these techniques responsibly and transparently.

The survey results provide a strong argument for the wider use of neuromarketing techniques in marketing campaigns. The findings confirm that neuromarketing can provide valuable insights into consumer behavior that can lead to more effective targeting of marketing activities and increased sales. However, implementing these findings in practice requires not only technical expertise but also ethical considerations to avoid consumer manipulation. Future studies should focus on the long-term effects of

neuromarketing campaigns and their impact on brand loyalty and consumer decision-making. It would also be useful to examine how neuromarketing approaches can be adapted to different cultures and demographic groups.

Conclusion

Neuromarketing represents a revolutionary approach to understanding and optimizing consumer behavior. It has become an invaluable tool in the field of marketing research, providing a deeper understanding of how cognitive and emotional attributes influence consumer behavior and decision-making. This knowledge allows marketers to create more targeted and effective campaigns that are better tailored to the needs of consumers. Integrating cognitive, emotional, and behavioral factors into marketing strategies offers marketers new tools to improve the effectiveness of their campaigns and increase sales. A systematic review of the literature confirms that these techniques can lead to significant results if properly implemented. Neuromarketing findings have the potential to significantly contribute to optimizing consumer behavior and increasing sales. The key to successfully implementing these findings is understanding and integrating cognitive, emotional, and behavioral factors into marketing strategies. The results of the preliminary survey provide a strong foundation for further research and applications of neuromarketing in practice, while emphasizing the need for an ethical approach to the use of these techniques.

Gender differences in responses to neuromarketing cues represent an important aspect in the development of marketing strategies. Recognizing and exploiting these differences allows marketers to create campaigns that are not only more effective, but also better able to reach different genders. Future research should focus on examining these gender differences in more detail and their practical applications in marketing strategies, which could lead to even more sophisticated use of neuromarketing techniques in practice. The future of neuromarketing also lies in further deepening knowledge about how the human brain responds to various stimuli and in finding new ways to use these findings in practice. Marketers, who can apply these techniques ethically and effectively, can also gain a significant competitive advantage in the marketplace. Further research should continue to explore the ethical aspects of neuromarketing and its long-term impacts on consumer behavior, focusing on creating transparent and responsible marketing strategies that respect consumers and support their choice. The ethical use of neuromarketing techniques is key to maintaining consumer trust and responsible marketing.

Abstract

Research background: In the context of a rapidly changing global environment, the ability of entrepreneurs to adapt and sustain their potential is increasingly important. Neuromarketing and neuro-linguistic programming (NLP) offer new insights into the subconscious mechanisms that influence personal development and decision-making processes. These tools can serve as a valuable asset in the pursuit of sustainable business and entrepreneurial practices.
Purpose of the article: The main objective of the paper is to identify and specify personal indicators of sustainable development in entrepreneurs through NLP. The research investigates how NLP training affects key characteristics related to entrepreneurs' adaptability and resilience in uncertain socio-economic conditions.
Methods: A sample of 208 entrepreneurs (96 women and 112 men), with an average age of 40.2 years, participated in the research. Of these, 112 participants had received NLP training, while the remaining 96 had not. The methodologies of Sustainable Human Capital (SHC) and NLP techniques (NLP-T), validated tools for assessing sustainable human capital indicators, were used to collect data. Statistical analysis aimed to identify significant differences between the two groups in terms of their experience with NLP training.
Findings and value added: The results revealed significant differences in personality indicators of sustainable human capital development between entrepreneurs who received NLP training and those who did not. The findings point to the potential of NLP as a tool to increase the adaptability and resilience of entrepreneurs. Integrating NLP with neuromarketing principles provides a new perspective on strategic human capital development.

1. Introduction

In an era characterised by dynamic and unpredictable global developments, the ability of entrepreneurs to adapt and maintain their personal and professional potential is becoming an increasingly important factor for long-term organisation success. The success of an organisation depends also on to the quality of decisions and judgements made by both individuals and work teams (Fasolo et al., 2024). Rapid technological advances, changing market demands and socio-economic uncertainty are creating an environment in which traditional business strategies are no longer sufficient. Instead, there is a growing need to explore innovative approaches that increase both cognitive flexibility and emotional resilience.

In this context, emerging interdisciplinary fields such as neuromarketing and neuro-linguistic programming (NLP) offer valuable tools for understanding the unconscious mechanisms that influence human behaviour, decision-making and personal development. These approaches not only enable entrepreneurs to better understand their own communication and leadership styles, but also foster stronger connections with stakeholders, clients and teams. Integrating NLP with neuromarketing principles provides a new perspective on strategic human capital development (Plassmann et al., 2012).

[*] Corresponding author: eva.benkova@unipo.sk

In this article, we approach neuromarketing as a multidisciplinary approach that combines insights from neuroscience, psychology, and marketing to better understand and influence customer behaviour, particularly by measuring subconscious responses. Neuromarketing instrumentation includes not only technologies such as eye-tracking or EEG, but also psychological tools and techniques (e.g. NLP) that can target the subconscious mechanisms that influence decision-making. From this perspective, NLP techniques have the potential to function as a neuromarketing tool, as they work with symbols, language patterns and non-verbal communication at a level that the recipient is not always consciously aware of.

1.1 Neuromarketing, NLP and unconscious mechanisms: common backgrounds

NLP shares many similarities with neuromarketing, especially when it comes to understanding the human mind and behaviour. Neuromarketing focuses on the study of the human brain's responses to various stimuli, including advertising. Studies suggest that both disciplines, neuromarketing and neurolinguistic programming, are effective tools in evaluating customer decisions and behaviour (Anazco et al., 2019).

While neuromarketing works with research on the brain's subconscious responses to stimuli that influence individuals' behaviour, often without their knowledge, neuro-linguistic programming (NLP) focuses mainly on conscious communication and personal development skills. However, both disciplines share an emphasis on information processing, emotional experience and decision-making processes that are not always consciously controlled (Plassmann et al., 2015).

Research in neuromarketing shows that up to 90-95% of decisions are made based on the subconscious (Zaltman, 2003). This means that the way we communicate, ask questions or use body language can have a neural impact, even if the recipient is not aware of it. Thus, NLP principles such as rapport, representational systems, or leading can influence not only cognitive understanding but also emotional and physiological response, which is the basis of neuromarketing.

For example, body language in neuromarketing is directly linked to the activation of mirror neurons - these are activated when observing other people's movements or expressions (Rizzolatti & Craighero, 2004). Thus, NLP, through the conscious use of body language, not only affect the ‘impression’, but can reach the neurobiological level of interaction. These areas are crucial for building trust, which is also a basic premise for forming successful business relationships.

NLP also works with linguistic patterns that can purposefully influence information processing at a subconscious level. In neuromarketing, the use of specific language or stories (narratives) has been shown to activate areas of the brain associated with self-experience (e.g., hippocampus, medial prefrontal cortex), thereby increasing emotional engagement and memorability of content (Zak, 2013). From this perspective, NLP can be seen not only as a communication tool but also as a method of subliminal influence, which is an essential element of modern customer experience-oriented marketing.

Properly applied, NLP techniques can, for example, increase the conversion rate of sales conversations in the same way that neuromarketing techniques increase the effect of advertising (Hult et al., 2017).

1.2 Neuro-Linguistic Programming (NLP)

Knight (2020) sees NLP as an attitude of learning, curiosity and respect for the unique way of being in the world, with its essence being the study of perfection. Hamill and Kerr (2013) add that many of our seemingly automatic responses are the result of learned sequences of thought and behaviour that run so fast that we perceive them as a whole. NLP analyses these behavioural structures and offers tools to consciously change and optimise them (Birknerová et al., 2022b).

Bandler et al. (2013) argue that NLP provides people with tools to change the way they think. It is a process of reprogramming thoughts that allows ideas to adapt to changes.

NLP is based on the premise that the point of communication is the response it elicits (Sandu, 2022). Effective communicators modify their language and communication style until they achieve the desired outcome. According to Knight (2020), the ability to create trust and understanding through language is one of the fundamental pillars of NLP. In this context, our research compared respondents who had received NLP training with those who had not, looking at differences in aspects of sustainable human potential development. El-Ashry (2021) states that neuro-linguistic programming greatly improves external communication with others in the workplace, using all the different communication mechanisms such as: understanding the other person's way of thinking, the hidden meaning of their words and their

actions, and also achieving common goals in the workplace. Finally, he adds that companies that use neuro-linguistic programming skills when communicating with customers achieve greater profits and superior customer service.

1.3 Aspects of sustainable human capital development

Sustainable human capital development is a strategic approach to shaping entrepreneurial decisions and developing people in both organisations and business environments that takes into account long-term needs, adaptability and the balance between performance, health and growth of the individual (Stajkovic & Stajkovic, 2025). Human capital sustainability includes not only traditional skill development, but also an emphasis on soft skills such as communication, collaboration, stress management, and the ability to learn, which enhance individuals' ability to respond to the challenges of the work environment and support their long-term psychological and occupational health (Wheeler, 2013).

From a business practice perspective, sustainable human capital development is closely linked to ethical leadership, self-reflection, knowledge sharing and continuous learning. Tools such as neuro-linguistic programming (NLP), which support the development of interpersonal and intrapersonal competencies, can contribute significantly to the sustainable strengthening of entrepreneurs' human capital. Sustainable development in this sense is not just about temporarily improving performance, but about building resilience, adaptability and long-term growth for the individual and the business environment as a whole.

2. Methods

Based on the theoretical knowledge and the results of the research (Frankovský et al., 2018), the aim of the presented research project was defined. The research aimed to identify and specify indicators of sustainable human capital development and to verify the existence of statistically significant differences in the level of aspects of sustainable human capital development between respondents who have received NLP training and those who have not. Based on the above objectives, the following hypotheses were formulated:

H1: We assume that it is possible to identify and statistically extract relevant factors of sustainable human capital development (SHC) indicators.

H2: We assume that there are statistically significant differences in the identified factors of sustainable human capital development between respondents who have received NLP training and those who have not received NLP training.

H3: We assume that there are statistically significant differences in the application of NLP techniques (NLP-T) between respondents who have received NLP training and those who have not.

We tested the hypotheses using two methodologies: Neuro-Linguistic Programming Techniques (NLP-T) and Sustainable Human Capital Development Indicators (SHC):

NLP-T: Neuro-Linguistic Programming Techniques (Frankovsky et al., 2018) – it explores neuro-linguistic programming techniques. The methodology includes 15 items that are assessed on a 5-point Likert-type scale (0-definitely no, 1-no, 2-rather no than yes, 3-rather yes than no, 4-yes, 5-definitely yes). Three factors were defined by factor analysis:

Representational systems - the belief that every human being views the world around them preferentially through one of the five sensory systems. Each person has his or her own, so-called, preferred sensory system, which one uses most advantageously and in which one feels best.

Rapport - creates an ideal state of communication based on trust and understanding that business people can use to influence behavior, initiate change, and persuade people.

Leading - guiding, accompanying or directing. Adapting to and creating harmony with a partner for a period of time should lead to the creation of a sufficient relationship that will then allow us to lead the partner to where we want to go.

SHC: Sustainable Human Capital Development Indicators (Frankovsky et al., 2019) - the methodology consists of 11 statements related to sustainable human capital development that underpin NLP. Each statement contains 6 possible ways of responding to the level of agreement with it (0-decidedly no, 1-no, 2-rather no than yes, 3-rather yes than no, 4-yes, 5-definitely yes). As an example, we give the statement ‘There is no failure, there is only feedback.’ ‘I have all the resources I need to make a change.’.

In the research presented here, data were collected from a pool of 208 entrepreneurs, of which 96 were women (46.2%) and 112 were men (53.8%). The average age of the respondents in the research sample was 40.2 years (standard deviation 10.187 years) ranging from 26 to 64 years. The average number of years of service of the respondents was 17.83 years (standard deviation 10.564 years) ranging from 1 to 40 years. Training in Neuro-Linguistic Programming (NLP) was completed by 112 respondents (53.8%), of whom 51 were male (45.5%) and 61 were female (54.5%) with a mean age of 41.5 years. 96 respondents (46.2%) did not undergo NLP training, of which 42 were male (43.8%) and 54 were female (56.2%) with an average age of 39.7 years.

3. Results

The data obtained allowed to perform factor analysis (Principal Component Analysis with Varimax rotation) and difference analysis (Student's t-test) using the statistical program IBM SPSS Statistics 26. The normality of the data distribution was tested using Skewness and Kurtosis.

Identification and specification of indicators of sustainable human capital development

Factor analysis, based on KMO test (.814) and Bartlett's test (585.2, sig. .000), Principal Component Analysis with Varimax rotation was used. Two factors were extracted (Table 1):

1. Uniqueness is assessed in terms of effective communication even without words. Unique individuals have their body and mind in harmony and perceive the world in a unique way. They are not afraid of change because they believe they have all the resources they need.
2. Positivity is perceived in terms of success, positive direction and intention. Positive individuals work to the best of their ability in a given situation. They always have the choice to change lives when other individuals have been able to do so.

The data obtained enabled factor analysis (Principal Component Analysis with Varimax rotation) and difference analysis (Student's t-test) to be carried out using the IBM SPSS Statistics 26 statistical program. The normality of the distribution of the data was tested using Skewness and Kurtosis.

Table 1. Factor structure of the SHC methodology

	Component		
	F1 Uniqueness	**F2 Positivity**	
I communicate even when I say nothing.	.638		
The meaning of communication is the response it evokes.	.799		
Every behaviour has a positive intention.		.785	
There is no failure, there is only feedback.		.764	
One works as best one can in a given situation.		.893	
The mind and the body are part of the same system.	.853		
All of us perceive the world in a unique way.	.891		
The possibility of choice is life-changing.		.673	
The same procedure equals the same results.	.741		
If someone has done it, others can do it, too.		.614	
I have all the resources I need to make a change.	.697		
Component	**Initial Eigenvalues**		
	Total	**% of Variance**	**Cumulative %**
F1 Uniqueness	5.187	47.143	47.143
F2 Positivity	1.382	12.557	59.699

Rotation Sums of Squared Loadings		
Total	% of Variance	Cumulative %
3.798	34.532	34.532
2.768	25.169	59.699

Source: own processing (2025)

The extracted factors explain 59.699% of the variance. This percentage of variance explained by the extracted factors is acceptable; the factors could be content-specific. The internal consistency of the factors was ascertained by calculating the Cronbach's alpha coefficient (Tables 2, 3).

Table 2. Internal consistency of the Uniqueness factor

	Scale Mean if Item Deleted	**Scale Variance if Item Deleted**	**Corrected Item-Total Correlation**	**Cronbach's Alpha if Item Deleted**
I communicate even when I say nothing.	20.72	16.199	.549	.863
The meaning of communication is the response it evokes.	20.43	16.598	.695	.829
The mind and the body are part of the same system.	20.25	17.277	.729	.832
All of us perceive the world in a unique way	20.27	16.685	.709	.826
The same procedure equals the same results.	20.26	17.662	.619	.844
I have all the resources I need to make a change.	20.56	16.018	.656	.836

Cronbach’s alpha F1 Uniqueness = .867
Source: own processing (2025)

Table 3. Internal consistency of the Positivity factor

	Scale Mean if Item Deleted	**Scale Variance if Item Deleted**	**Corrected Item-Total Correlation**	**Cronbach's Alpha if Item Deleted**
Every behaviour has a positive intention.	15.14	13.037	.589	.759
There is no failure, there is only feedback.	15.29	11.469	.664	.736
One works as best one can in a given situation.	15.52	11.594	.672	.735
The possibility of choice is life-changing	14.63	15.656	.479	.796
If someone has done it, others can do it, too.	14.78	13.944	.536	.778

Cronbach’s alpha F2 Positivity = .799
Source: own processing (2025)

The above Cronbach's alpha values indicate a satisfactory level of internal consistency of the extracted factors of sustainable human capital development. Based on the above results, hypothesis 1, 'We assume that it is possible to identify and specify indicators of sustainable human capital development,' can be considered as verified.

Identification of differences in the factors of sustainable human capital development

Mathematical and statistical analysis of the data was carried out using Student's t-test in the statistical program SPSS 26. The results found are presented in Table 4.

Table 4. Differences in the assessment of sustainable human capital development factors

	NLP training	Average	Standard deviation	T-test	Significance
F1 Uniqueness	not received	3,32	,798	3,492	**,002**
	received	**3,98**	,748		
F2 Positivity	not received	3,15	,727	4,458	**,000**
	received	**4,23**	,533		

Source: own processing (2025)

We found that respondents who had received NLP training judged the SHC factors more positively than did respondents who had not received NLP training.

The first indicator of sustainable human capital development that proved to be statistically significant is the trait of Uniqueness. This characteristic reflects individual uniqueness and the ability to develop one's potential, with development also possible at a subconscious level. The second significant factor was the Positivity indicator, which refers to the ability of individuals to orient themselves towards constructive and goal-directed behaviour

Identification of differences in the application of NLP techniques

The mathematical and statistical analysis of the data was carried out using Student's t-test in the statistical program SPSS 26. The responses of the respondents who had or had not undergone NLP training were compared. The findings are presented in terms of the 3 extracted factors of the degree of application of NLP techniques (NLP-T methodology): Representational Systems, Rapport and Leading (Table 5).

Table 5. Differences in the assessment of the degree of applying NLP techniques

	NLP training	Average	Standard deviation	T-test	Significance
F1 Representational systems	not received	3,27	,788	3,143	**,005**
	received	**3,99**	,756		
F2 Rapport	not received	3,46	,728	4,637	**,000**
	received	**4,73**	,517		
F3 Leading	not received	3,13	,746	2,356	**,004**
	received	**3,91**	,562		

Source: own processing (2025)

The results presented in Table 5 show statistically significant differences ($p < 0.05$) in all three factors between the group of respondents who had received NLP training and those who had not. Respondents who had received NLP training showed a higher rate of application of NLP techniques across all the domains studied. Specifically, in the area of representational systems, NLP training participants demonstrated higher levels of awareness and use of preferred sensory modalities in communication. Under the rapport factor, respondents confirmed that they were able to purposefully build trust and harmonious relationships through adapting to their partner's communication after the training. In the third factor, leading, respondents who had received training reported a greater ability to guide

communication towards the desired outcome through establishing a connection and then guiding the partner according to NLP principles.

4. Discussion

Statistically significant differences were found in the identified factors of sustainable human capital development. Respondents who received NLP training showed higher scores, especially in areas such as conscious perception of communication, flexibility and openness in expression, ability to work with the meaning of information, as well as self-reflection. These factors are considered important aspects of human capital development, especially in the context of working with people and in environments where quality interaction is vital. There were also statistically significant differences in the application of NLP techniques (NLP-T). Respondents who had received NLP training were more likely to rapport actively using techniques such as working with representational systems, rapport generation and communication (leading).

The results are also consistent with existing findings from the literature. For example, research conducted in India (Singh, 2008) confirms that NLP techniques can be useful for managers and employees in increasing work effectiveness and building a better understanding in teams. Similarly, Tripathi (2012) highlights the importance of NLP in recognising one's own emotional and behavioural patterns, which can help individuals develop both interpersonal and intrapersonal skills. Research results suggest that NLP training not only increases the conscious level of communication skills, but can also influence the subconscious (unconscious) processes that underlie emotional response, trust formation and decision-making.

These aspects are the subject of neuromarketing research. These processes refer to psychophysiological reactions and mental operations that take place below the threshold of conscious perception, yet fundamentally influence an individual's emotional experience, decision-making and behaviour. Key NLP techniques such as rapport, leading or working with representational systems can lead to the activation of brain structures (Birknerová et al., 2022a). These processes often take place outside the conscious control of the communicators, which means that NLP can also function as a tool for subconsciously optimising interaction (Budiman et al., 2018).

The present study primarily draws on data collected through questionnaire methodologies, which are based on the subjective assessment of the respondents and do not fully capture the real subconscious reactions that often take place outside of conscious awareness. Future research may combine self-assessment and behavioural data with biological indicators of unconscious responses. We also plan to validate our findings with tools such as eye-tracking, which allow us to objectively monitor respondents' unconscious reactions in real time.

Conclusion

These findings open up a new research area - investigating the effects of NLP techniques not only through questionnaire methods, but also using neuroscientific and psychophysiological tools that allow monitoring of immediate and unconscious reactions. Such an approach could provide new insights into the effectiveness of NLP and its potential use in the fields of neuromarketing, coaching and managerial communication.

From a business practice perspective, it is important to recognise that the application of NLP in business goes beyond conventional verbal strategies and involves shaping the customer experience, building credibility and influencing decision-making behaviour over the long term - often at a level that the recipient is not even aware of. This ability to reach the “subconscious” is why NLP is also relevant in the context of modern neuromarketing.

In the context of marketing practice, NLP techniques can be used effectively in creating advertising messages, building customer trust and increasing conversion rates through targeted communications that reflect customers' preferred sensory modalities.

Advertising Literacy and Implicit Reactions to Brand Benefits: A Case Study of Research on Implicit Reactions as a Complement to Verbal Feedback

***Tamás* Darázs**[1,*]

[1] University of Ss. Cyril and Methodius in Trnava, Faculty of Mass Media Communication, Námestie Jozefa Herdu 2, 917 01 Trnava, Slovakia

Abstract

Research background: advertising literacy is traditionally understood as the ability to recognize an advertisement, understand its intent and critically evaluate its content. In practice, however, consumers often react affectively rather than rationally - and their bodily reactions may signal rejection before they are consciously aware of it. Neuromarketing methods thus represent a valuable tool for exploring those layers of perception that remain outside verbal articulation, but may be key to understanding advertising literacy as a complex set of cognitive and emotional processes.
Purpose of the article: The aim of the study is to investigate how implicit bodily reactions can serve as an indicator of the level of advertising literacy of the audience. Using the example of the Digital University brand campaign, we analyze the reactions to the terms "MBA" and "online learning", which were declared as benefits. We focus on cases where the audience did not verbally express disagreement, but biometric data (GSR and facial coding) revealed a hidden affective aversion.
Methods: An exploratory case study used a combination of facial coding (Affectiva SDK), GSR (Shimmer) and eye-tracking (Smart Eye Aurora) on a sample of 19 respondents. An advertising spot with repetitive expressions was analyzed.
Findings & Value added: The results show that some concepts, while not causing conscious rejection, do cause affective mistrust. These reactions can be seen as a bodily expression of advertising literacyliteracy - as a prior stage of critical processing. The study proposes to integrate neuromarketing methods into both research and branding practice, especially with target audiences that are sensitive to authenticity.

Keywords: Advertising literacy, Affective trust, Biometric response, Brand communication, Emotion measurement, Implicit reactions, Neuromarketing.

JEL classification: M31, D91, M37

1. Introduction

Advertising literacy has traditionally been defined as the ability to recognize advertising, understand its intentions, and critically evaluate its content (Rozendaal et al., 2011). This view is further supported by Čábyová, Krajčovič and Hudáková (2023), who emphasise that advertising literacy in the current media environment includes the ability to detect misleading environmental claims and to evaluate the credibility of advertising content in the context of greenwashing practices. However, this concept is difficult to measure in practice solely through stated responses - especially if we also want to understand the emotional impact of advertising (Hobbs, 2017). Researchers have long recognised that advertising also operates non-verbally, emotionally and implicitly - which raises the question of how consumers actually process it (Gordon, 2006). The difference between what consumers think and what they feel can be substantial (Krajčovič & Darázs 2021).

As a research approach, neuromarketing also allows us to investigate responses to advertising that are not verbalized. Biometric measurements such as galvanic skin response or facial coding have the potential to add to our understanding of how humans process advertising content (Čábyová et al.,2024).

This case study is intended to show what can be learned by observing not only what people say, but also how they react to advertising outside of their conscious minds. By analyzing biometric responses to specific expressions in the Digital University brand campaign, we reveal situations in which respondents' bodies express disapproval or disbelief - even though verbal reactions remain neutral or positive.

We show that implicit responses can be an important part of ad content processing, and that tracking these responses can expand the way we think about ad literacy, brand trust, and overall ad perception.

In this sense, advertising literacy is not limited to the ability to verbally identify advertising, but also includes affective competence - i.e. the ability to respond physically and emotionally to the non-verbal aspects of communication. The concept of "affective advertising literacy" is not yet settled in the literature, but this research shows that emotional processing of advertising can reveal important patterns of implicit judgment and credibility that remain hidden in rational evaluation. The results of this type of research can be seen as a manifestation of an expanded understanding of advertising literacy - not only in what audiences are aware of, but also in how their bodies react to the way an advertising message is framed. In the context of biometric data, we thus observe implicit signs of 'understanding' advertising that may express tacit disapproval, scepticism or emotional dissonance.

This article analyses the case of the Digital University brand, which built its video campaign on two main benefits: the MBA degree and the online form of study. From a traditional marketing perspective, these are strong benefits - declared as modern, flexible, practical. Conscious evaluations by respondents did not reject these statements: no significant questioning emerged in questionnaires or interviews.

But neuromarketing data showed something else: the body reacted with contempt, a decrease in bias, or even anger - at the very moments when these "benefits" appeared in the video.

What does it mean when an audience consciously agrees but their implicit responses tell a different story? And what does this say about branding as a discipline that today increasingly works with data but doesn't always understand its meaning? And what do consumers understand of it?

The understanding of marketing communication and brand message does not originate in the office environment, but in the experiences of the people who come into contact with it. In modern marketing communications, it is not enough for a brand or communication to 'make sense'. It has to be emotionally grounded, credible, and affectively experienced (Bilotti, 2011). The emotional connection between the communication and the audience is a critical factor in loyalty - rational benefits are just a ticket, but not a reason to stay (Joshi & Nema, 2015).

Brands and their communications that ignore the emotional register seem to risk 'affective failure' - a situation in which audiences may understand the words, but do not believe them with their bodies (Rostomyan, 2014). This is especially true for audiences that are vulnerable to inauthenticity and marketing machinery - for example, Generation Z, whose relationship with brands is fragmented, cautious, and often tested by emotional resonance, not argumentative force (Feng et al., 2024)

Statements that are meant as benefits thus run up against cultural and bodily filters. Neuromarketing in this case does not reveal "what people think". It reveals tacit bodily disagreements that don't appear in rational discourse - but which determine whether we trust a brand and how we perceive it.

Also, theoretical frameworks point out, a communication or brand that is not lived - even if it were technically correct - remains alien (Rosenbaum-Elliott et al., 2018; Ho, 2020; Powers & Pattwell, 2015).

The aim of this study is to show how tracking biometric responses can enrich the understanding of advertising literacy, especially in cases where verbal expressions do not capture the full range of brand perception. However, to better understand how advertising literacy works, we must also pay attention to those layers of perception that take place below the level of consciousness - in the subtle, often hidden bodily responses that precede rational judgments of advertising. In this sense, advertising literacy manifests itself not only in the ability to identify advertising, but also in the ability to respond bodily to its (inauthenticity. If the audience perceives a difference between the declared and the actually experienced meaning, their emotional reaction may be the first indicator of advertising literacy or a refusal to trust the message.

2. Methods

This article presents a case study with an exploratory nature, which aims to analyse the implicit affective responses of the audience to specific value elements of the Digital University brand - in particular, to the notion of *MBA* and *online learning*, *revealing* differences in stated and lived perceptions. Digital University is a Slovak educational platform that offers online MBA and other professional

programmes focused on practical skills and flexibility. The brand operates in the Czech and Slovak markets and focuses on students who want to study alongside work or remotely. Teaching is fully online, with an emphasis on *up-to-date content, practitioner tutors and professional branding*.

This study focuses exclusively on one particular video under test - referred to as V1. It was a short video review filmed in the streets of Bratislava, linking the testimony of the main lecturer with the testimony of the graduates. The opening part of the video features the lecturer - a well-known motivational speaker and coach working in the Central European area - who introduces the benefits of studying and presents the brand values. This is followed by personal testimonies from the graduates, ending with a return to the brand challenge. The video has a professional format and is typically representative of branded content designed for social media.

It was in this video that the most affective reactions were observed in relation to the statements about "MBA" and "online learning". Therefore, V1 is the main focus of analysis in this study.

The study is based on a research collection that was conducted as part of a broader pre-test of the Digital University's advertising materials. The impetus for the research was an internal initiative of one of the employees of this educational institution, who, as part of her master's studies at the Faculty of Mass Media Communication at UCM, conducted a master's thesis focused on the evaluation of the campaign's video formats.

Although the research did not originate as a formal commercial assignment, its design, implementation and interpretation were conducted with the intention of providing actionable insights to optimise the brand's communication strategy. The research was conducted under expert supervision and using professional equipment in the NEUROLAB neuromarketing laboratory at the FMK UCM in Trnava.

However, the aim of this study is fundamentally different from the aim of the thesis. While the thesis compared the effectiveness of different video formats and looked for the 'best' way to communicate the campaign as a whole, this paper purposefully focuses on one of the most contextually interesting phenomena that repeatedly emerged across the different formats - namely, affective responses to the words 'MBA' and 'online study'.

Thus, this research does not seek to compare video formats, but to conceptually analyse what happens when a brand communicates values that, while appearing to be rationally advantageous, are physically experienced as problematic.

The research question addressed in the text is: *What implicit affective reactions are elicited by the communication of the value of "MBA degree" and "online learning" in the context of the Digital University brand - and what do these reactions say about its affective credibility?*

The nature of the study is qualitative-interpretive. We do not work with hypotheses or statistical inference. The aim is to identify and interpret specific affective patterns that are not articulated consciously by the respondent, but are detectable through biometric indicators and visual attention tracking.

Data collection took place on 27 February 2024. The study population consisted of 19 respondents aged between 20 and 50 years, who were purposively selected based on their assumed similarity to the Digital University target group. The sample consisted of working students, self-employed people, marketing professionals, entrepreneurs and people interested in external or flexible learning.

Five promotional videos were shown to the respondents. The videos were played in random order to avoid the influence of attention and order. They all contained elements that communicated the benefits of studying - and among these, two key ones were recurring: *the MBA degree* and the *online form of study*.

Technically, the research was carried out using three basic biosensory methods:

- eye-tracking (Smart Eye Aurora) - tracking the distribution of visual attention and AOI,
- facial coding (Affectiva SDK) - capturing basic emotions by facial expressions,
- GSR (Shimmer sensor) - recording electrodermal activity as an indicator of emotional arousal.

After playing the videos, each participant completed a questionnaire designed to compare conscious ratings with implicit responses. It is noteworthy, however, that it was the occurrence of "MBA" and "online learning" that showed no complaints or negative comments in the questionnaires, whereas the biometric data showed the opposite - disdain, decreased attention, micro-expressions of disgust or disinterest.

In this study, we exclusively analyze these recurring moments - not entire videos or their composition, although there were also some fluctuations (e.g., in illogical editing or foreign names of performers).

Ethical aspects of the research were observed. Informed consent was provided by the respondents, the research was anonymous and focused solely on non-invasive observation of behavioural and physiological responses.

The limitations of the research lie in the small sample size and the specific composition of the participants. However, the intention was not to make generally valid recommendations, but to highlight a conceptually important phenomenon that would have gone unnoticed in classical research: that a brand can communicate values that, although not consciously questioned by the audience, are affectively rejected by them.

3. Results

In this part of the study, we focus exclusively on one of the tested videos - video V1, whose structure and format we have described in detail in the methodology section. The reason for the selection is not only based on the strength of the biometric response, but also on its fundamental role within the brand campaign. Of all the formats tested, it was the most classic promotional output in which the brand directly declares its main benefits - namely *the MBA degree* and *online study*. The other videos in the tested series varied in nature: they were either authentic accounts of life, personal stories or slightly ironic, humorous spots without strong brand statements.

That is why the analytical focus of this study is on video V1 - not only as a carrier of expression, but as a representative of the overall communication rhetoric of the brand. Indeed, the expressions used in this video are *brand-speak in its pure form* - they are formulations that have been created 'at the table', not in the field.

This raises an important question: What happens when a brand declares an advantage, but the body of the audience doesn't experience it as an advantage? Can we talk about a loss of trust? Or more precisely: a loss of affective trust - the type of trust that is not based on argument, but on bodily resonance.

Emotional response to advertising is key to creating lasting memory and subsequent consumer behaviour. Emotions activate the limbic system, which plays a crucial role in decision making and the formation of trust in a brand (Kaushik et al., 2024). Emotional reactions influence a consumer's attitude towards a brand and their subsequent decisions - positive emotions can reinforce trust, while negative emotions can undermine it (Bungatang et al., 2023).

Another specific aspect of this analysis is the target group that the video clearly aims at: young adults - mostly from a Generation Z background - who combine study and work and naturally expect flexibility, digital environments and authenticity. At the same time, however, this is a group that is highly sensitive to inauthenticity, unnatural forms of presentation or a 'marketing tone' that is not emotionally anchored.

The affective response of a brand - especially in the case of Generation Z - is thus not only determined by vocabulary, but also by whether a given term "fits into the world" they already know and live. If an utterance isn't emotionally rooted, it won't pass through the body. And if it doesn't pass through the body, it is ineffective from a trust perspective - regardless of rational correctness.

In the context of this study, therefore, we are looking at elements of affective mismatch - situations where a brand says something that the audience does not verbally reject, but their body responds with resistance, a decrease in engagement, or an absence of trust. These moments are tacit but measurable - and can be just as important as verbal caveats or changes in attitudes.

So we are not analysing the performance of the campaign as a whole. We do not examine which video had the best impression. We are looking at a more subtle phenomenon: specific moments in which the audience affectively rejects what the brand declares as an advantage.

The following three subsections are devoted to three such moments captured in video V1:

- first response to the term *"MBA"* in the introduction of the video,
- second response to *"MBA"* in the mouth of a graduate,
- and in response to a statement about *online learning* that was intended as a benefit but caused emotional distance.

3.1 First reaction to "MBA" - the lecturer as the voice of the brand

The first critical point in the V1 video is the lecturer's statement at the ninth second:

"The opportunity to earn an international MBA."

In terms of marketing rhetoric, this is a classic example of a claimed benefit. The statement is clear, positive, embedded in the language of career progression. Within the structure of the video, it is also the

first peak of meaning - the audience is just entering the narrative and the brand is signalling here what it wants to be: modern, prestigious and trustworthy.

However, the data show that it is at this point that the affective break occurs. In the ninth second of the video it occurs:

- a decrease in electrodermal activity (GSR) of approximately 29% within four seconds,
- and at the same time, expressions of contempt - nonverbal expressions that indicate rejection, feelings of superiority, or emotional distance - appear in facial coding data.

This fluctuation cannot be interpreted as the result of general inattention - up to this point, the audience's physiological engagement was stable and slightly elevated, indicative of underlying emotional engagement. Thus, the video was building trust at the outset. However, the statement about the MBA disrupted this rhythm. It was as if there was a note in the harmonic flow that didn't fit.

We can speak of a distortion of the affective trajectory - a statement that was meant to strengthen confidence instead weakens it. The body does not respond with assent, but with silent rejection.

There are several possible causes for this reaction:

- Ignorance of the acronym MBA - some respondents may not have understood it or associated the term with something irrelevant (e.g. professional sport),
- The perception of the term as elitist - an MBA degree can convey a sense of distance, superiority, or even the idea of a "bought education",
- Low credibility of the utterance - the utterance comes across as a learned brand, not a natural utterance. The lecturer as the voice of the brand does come across as professional, but perhaps that is why he is perceived as a marketing spokesperson, not as an authentic source.

As Romero Olucha et al. (2015) point out, the emotional response to an utterance depends not only on its meaning, but mainly on how it corresponds to the recipient's physical and cultural frame. The body does not evaluate grammar or logic - it evaluates confidence.

Particularly noteworthy is that this is the video's opening semantic highlight. At this stage, the brand hasn't yet built trust capital - on the contrary, it's in the process of building it. If the first affective disruption has already appeared at this point, the entire subsequent course of communication can take place in the shadow of this disruption.

This single utterance thus becomes the point of an affective turning point. Not because it is factually incorrect. But because it failed to pass through the body. And it is these micro-frames that we focus on in this study - the seemingly insignificant seconds that decide whether or not we believe a brand.

However, it is also worth mentioning the cultural context - the research was conducted in Slovakia, where the MBA degree is not socially established. Its value is not generally perceived as unambiguous. Some consider it a prestigious degree, others a formal label. In this environment, it is not impossible that the expression of contempt captured in the biometric data was not just a bodily response to an unfamiliar concept, but an authentic expression of value disapproval.

In this short snippet of video, this may be mirroring a strategic problem that the brand is unaware of: it is communicating an advantage that not only doesn't work, but can be actively denied. And more seriously - it's doing it without knowing it.

Such a finding goes beyond campaign optimization. It may be a significant reputational issue that requires careful reflection, perhaps even a stand-alone educational or trust-building campaign that aims not only to name the benefit but also to embed it in the experience and values of the target group.

3.2 The second reaction to the "MBA" - authentic testimony without trust

The second significant moment, when the *MBA* degree appears within the V1 video, comes later in the sequence of Digital University alumni testimonials. This time it is not the statement of a professional lecturer, but the personal experience of one of the graduates, which is intended to strengthen the credibility of the brand through the so-called "social proof" - that is, through people who have used the product and believe in it.

Here, the brand changes its communicative role: it moves from a representative (lecturer) to a witness (graduate). This would be expected to gain authenticity. But paradoxically, it is at this point that the affective response occurs again, suggesting that the mere rephrasing of the expression is not enough.

By the time a graduate mentions the MBA, it appears repeatedly in the data:

- expression of contempt,
- decrease in emotional engagement,
- and in some cases an increase in sentimentality, which may suggest a mixture of confusion, irony or subliminal disapproval.

Compared to the first situation, a strange paradox arises here: the audience no longer hears the statement from the mouth of a "brand announcer", but from the mouth of an "ordinary person" - and yet (or perhaps precisely because of this) the reaction is just as affectively negative.

This phenomenon may be related to several factors:

- Low persuasiveness of the utterance - if the utterance is not delivered persuasively (body language, intonation, word choice), the audience may perceive "readiness", thus weakening authenticity,
- Appearance-statement discrepancy - if the respondent's appearance, language, or emotional tone clashes with the MBA concept, cognitive tension arises, which the body may respond with resistance,
- Unintelligibility of purpose - if a statement acts as an "add-on" to a statement without context, the audience may interpret it as meaningless or even imposed.

It seems that if a statement feels like a mechanical component or is emotionally out of tone with the rest of the scene, it can be dismissed as inauthentic.

In this particular situation, it turns out that even "live testimony" is not enough if it is not experienced as credible. Just because a statement comes from the mouth of 'one of us' does not guarantee that it will be accepted by 'us'. On the contrary - it can reinforce the effect of inauthenticity if the audience perceives that it is just 'another announcer' with another actor's lines. The affective reaction thus paradoxically shows that the problem may not only be the form of communication, but the content of the utterance itself. That is, not *who* says it, but *what is* said - and *how* it resonates in context.

Here again, the importance of the cultural framework becomes apparent. As we indicated in the previous chapter, the MBA is not firmly embedded in the cultural discourse in Slovakia. While in some countries it is seen as a clear symbol of prestige, in our country it can mean many things - or nothing. This context also influences the perception of graduates' statements - not as evidence of confidence, but as repetition of a word that is not yet emotionally embedded in the target group's map of values.

In the end, even the strengthening of authenticity (through the form of the utterance) does not compensate for the lack of affective anchoring (content). The utterance "MBA" may have sounded different, but it was not received differently. And this is an important signal for the brand.

If the benefit is not accepted even by those who have supposedly already gone through it, it may mean that it is not just a problem of communication, but a problem of perceived value itself.

This finding reinforces a previous hypothesis - that the MBA degree is not just unfamiliar or formal, but that there is some form of affective distance associated with it. And it is perhaps for this reason that it requires not just a "better campaign" but a new embeddedness in the cultural and emotional fabric of the audience.

3.3 Online learning as a word marked by crisis

The third critical moment in the V1 video is the lecturer's statement about the possibility of studying from home - i.e. about the online form of studying. This statement appears at about the 31st second of the video.

Like the *MBA* concept, "online learning" is also presented as an advantage in the communication strategy of the Digital University. The brand thus communicates flexibility, convenience, independence - all elements that are often associated on a conscious level with a positive evaluation of education in the digital space.

However, the data shows that the body reacted differently:

- at the time of this statement there was a decrease in joy,
- the emotion of contempt reappeared,
- and the GSR curve showed a decrease in activation, indicating a decrease in emotional involvement.

From the perspective of the classical logic of benefits, this is a surprising reaction. After all, online learning is flexible, convenient, accessible - and generally seen as one of the major trends in modern education. Why, then, would this particular statement elicit such an affective response?

The affective history of the word "online" offers one possible explanation.In the cultural memory of young adults - and especially Generation Z - the notion of *online learning* is closely associated with the pandemic period. A time of isolation, of technical chaos, of absent contact, of frustration with learning that was limited to "screen survival."

This effect can be referred to as the affective inheritance of the expression. Terms such as *online learning* may be technically neutral, but they are emotionally steeped in the audience's prior experience. This is particularly important if a brand is working with a young target audience that has experienced pandemic studying as a pivotal life experience.

Words like *online*, therefore, cannot be communicated without considering the emotional layers that resonate within them. From an identity-based branding perspective, there is again a tension between brand intent and audience perception. The brand wants to be modern and practical. However, audiences may experience this statement as a reminder of insecurity, isolation and emotional exhaustion.

Of particular importance is that this is the second occurrence of a semantic distortion within the same video - again in the mouth of the lecturer. This reinforces the hypothesis that the problem is not with the individual, but with the dictionary. The brand uses terms that it considers to be benefits, but which the audience - physically, emotionally - does not read as benefits. This type of contradiction may not appear at all on a conscious level. Questionnaires and interviews can remain 'clean'. All the more important is the use of neuromarketing methods that can capture the discrepancy that the conscious mind does not express - but the body experiences. The affective response to *online learning* is thus not a rejection of the concept per se, but a mismatch between the brand intent and the emotional context in which the concept takes place.

In the end, the brand says nothing wrong. But it speaks it in the wrong language of experience. So if the Digital University brand wants to communicate benefits like flexibility or accessibility, perhaps using the word "online" isn't enough. Perhaps it needs to reframe the term, examine its affective traces, and find a way to disentangle it from pandemic memory. Otherwise, it will continue to function as a silent confidence blocker.

3.4 Summary of affective patterns

The three situations analysed - the lecturer's statement about the MBA, the graduate's statement about the MBA and the mention of online learning - represent clear points of value communication from a brand perspective. They were meant to signal credibility, flexibility, career growth. However, biometric data shows the opposite: a decline in GSR, the appearance of contempt, a decrease in emotional engagement. The common denominator in all three cases is the affective mismatch between what the brand declares and how the audience - bodily - experiences it. These reactions could be interpreted as isolated if they did not occur repeatedly. And more importantly - they were not consciously noticed. After watching the videos, respondents completed questionnaires in which they indicated reservations about formal and compositional elements (e.g., choice of actors, editing illogicalities, or foreign names). Terms such as *MBA* or *online study* did not appear in the questionnaires - their 'problematic' nature only became apparent in the later analysis of the biometric traces. These findings underline the importance of what (Brenninkmeijer et al., 2020) refer to as *silent data* - data that the body records without consciousness naming it. Neuromarketing methods (GSR, facial coding) thus provide insight not only into audience reactions, but especially into reactions that would remain hidden by classical research methods. The emotional response is not determined by the meaning of the utterance, but by the context in which it takes place - both cultural and bodily (Bagozzi et al. 1999). The body does not evaluate grammar or logic - it evaluates confidence. And it is the latter that has been eroded in moments when the brand has communicated values that, while not consciously rejected, have not been affectively embraced by the audience.

The term *MBA* was heard in the introduction from the mouth of the lecturer - a representative of the brand - and later also from the mouth of the graduate, i.e. the person who was supposed to legitimise it through personal experience. In both cases, however, there was a marked decrease in GSR activity and the appearance of the emotion of contempt. This type of reaction is not usual in misunderstanding - on the contrary, contempt is a sign of rejection, disrespect or the perception of the expression as "inflated" and

untrustworthy. Thus, the look of contempt on faces that appeared repeatedly may not just be a random micro-revelation - it may be symptomatic of a brand communicating a concept that the audience either does not believe or finds empty. It is also problematic from a trust perspective that the brand first entrusted this statement to a lecturer - a person with authority, but also with a visible distance from the target audience - and then had it confirmed by the graduates. This repetitive narrative, if not emotionally compelling, only reinforces affective alienation. A statement that was intended to act as evidence of trust ultimately becomes evidence of misunderstanding. In terms of affective experience, then, it turns out that words like "MBA" may be rejected not because they are wrong-but because they do not carry support in the audience's bodily memory. Their problem is not meaning but emotional loneliness.

The same mechanism of trust failure shows up with the term *online learning*. In the cultural memory of young adults - and especially Generation Z - this term is closely associated with the pandemic period. A time of isolation, of technical chaos, of absent contact, of frustration with learning that was limited to screen-based survival. Words like *flexibility* or *flexible learning* can convey benefits - but when tied to negative affective experiences, communication fails without the brand noticing.

The affective failure of the brand here is not the result of a typo or a bad campaign. It is the result of the brand benefits not being embedded in the value maps of the audience. In this case, however, the concept of *the MBA* and *online learning* were not experienced as credible - and therefore remained emotionally alien. The brand therefore says nothing wrong. But it is saying it in a language that the audience doesn't believe. The communication may be formally correct - but without emotional rootedness, it communicates into the void.

In this context, it is important to recall that it is neuromarketing that has provided the opportunity to identify these "invisible" moments. Traditional questionnaires would not - and indeed did not - draw attention to them. The terms *MBA* and *online learning* did not appear as problematic in the questionnaire responses at all. And yet it was these words that elicited the most physiological reactions. Neuromarketing thus showed in this case not what people think - but what they unconsciously reject. As (Brenninkmeijer et al., 2020) aptly state, it is biometric tools such as GSR or facial coding that are nowadays crucial for capturing the *silent data* - the silent disagreements that do not pass into conscious language, but decide whether we trust a brand. Without a neuromarketing approach, these patterns would remain invisible. And the brand could continue to communicate benefits that the audience understands with the mind - but rejects with the body.

4. Discussion

This study did not address whether an MBA degree is an advantage. However, the findings resonate with a broader academic redefinition of advertising literacy. Čábyová et al. (2023) argue that true advertising literacy must also encompass the ability to critically interpret not only rational messages, but also affective framings and persuasive tactics aimed at unconscious processing.Nor whether online learning is flexible. It focused on something more subtle, but more fundamental: how these concepts "pass through the body." And she showed that sometimes they don't pass at all. We can interpret these differences between conscious consent and nonverbal refusal as evidence of the importance of tracking implicit responses in advertising literacy research. Neuromarketing methods thus allow us to reveal deeper layers of media understanding that conventional questionnaires cannot capture." The data suggests that brand communications may be formally correct but emotionally blind. Audience reactions were not consciously dismissive. No objections to these values emerged in the questionnaires or interviews. And yet - it was in the moments when the brand communicated *an MBA* or *online learning* that the body of respondents withdrew. It lost engagement. It showed disdain. This paradox - between word and trust, between content and body - deserves deeper discussion. For it opens up four key strands that have implications for both research and branding practice. A brand is not just a carrier of meanings. It is a mirror of the affective trust that audiences attribute to it. If a brand says a word that the audience understands but does not feel, the result is not understanding - but coldness. The term *MBA* carries weight in the world of management - but it may not be emotionally anchored for a Slovak audience. On the contrary, it can be perceived as a fashionable shorthand that inspires not respect but distance. In the same way, *online learning* - although formally associated with flexibility - can evoke lockdown, chaos, loneliness in the minds of respondents. Trust is thus not broken because the brand misleads. It is breached because it speaks words that the body does not welcome.

In marketing, it is often assumed that if something is profitable, it will also be perceived as profitable. But this is not true. Emotions don't listen to benefits - they listen to context. As this study shows, the Digital University brand repeatedly emphasized two benefits: title and form. But neither was emotionally resonant. And therein lies the blindness - that the strategy sees the words but doesn't see their emotional legacy. The statement "you study from home" can only be a benefit if home is not synonymous with isolation for the audience. The statement "you will get an MBA" only works if the degree is not seen as an empty symbol. A brand that doesn't know this context runs the risk of making its benefits seem like foreign words in a familiar language.

If we relied only on questionnaires, we would not see this affective blindness. The respondents did not realize it. They did not articulate it. It was only present in the body. As (Brenninkmeijer et al., 2020) state, tools such as GSR or facial coding reveal *silent data* - silent micro-reactions that do not pass into language, but determine confidence. These signals are not noise. They are predictors of behavior that classical research often overlooks. Neuromarketing is therefore not a fancy gadget for special projects. It is a diagnostic tool. Like an EEG in medicine - it doesn't say what the patient feels, but it shows what their body is doing. And sometimes that's where the truth that consciousness hides lies.

A brand is not a lecture. It is a conversation. And a good conversation is not created by saying what we want to say - but by the other person's perception shaping how we speak. Affective blindness is one of the most dangerous mistakes in brand communication. Not because it's dramatic - but because it's silent. It doesn't sound remorseful. A complaint isn't written. Trust is just lost. So this study is not just about one campaign. It's about the fact that brands need to test not just what they say, but how the body receives it. And sometimes they find that the word they thought was an advantage - is a *hint of foul play* in the audience's experience. So the new sensibility in branding doesn't start with strategy. It starts with the ability to listen quietly.

Conclusion

The results of this study contribute to the discussion of advertising literacy (Arbaiza et al., 2023) with the idea that advertising literacy is not only the ability to recognize advertising per se, but also the ability to respond intuitively to its emotional and nonverbal layers. It is for this reason that we consider neuromarketing tools to be a valuable contribution to research on media education and the development of critical thinking in young consumers. This aligns with the conclusions of Čábyová et al. (2023), who highlight that enhancing emotional and media competencies is essential for equipping consumers to resist manipulative practices like greenwashing, especially in environmentally themed advertising. This case study has shown that communication can fail in credibility even when it communicates formally correct benefits. When the Digital University promotional video was analysed, it was found that terms such as *MBA* and *online learning*, which were the backbone of the campaign, elicited negative affective reactions from respondents - in particular, disdain and a decrease in emotional engagement. At the same time, these reactions were not present in any conscious statements. Respondents did not cite them as problematic, which only confirms the importance of working with implicit data in brand research. It is neuromarketing tools that reveal these tacit bodily disagreements that determine whether a brand generates trust - or not.

The findings of this study offer two key recommendations for both practice and research on advertising literacy:

1. Brands should test not only the choice of communication terms, but also their emotional embeddedness in the target group. Terms that look like benefits on paper (e.g. 'flexibility', 'online learning') may in fact evoke negative associations - especially if they are not culturally or affectively experienced. Young people's advertising literacy also manifests itself in the fact that they intuitively recognise these meanings, even if they do not articulate them.
2. Biometric measurements should not be seen as an add-on, but as an integral part of advertising perception research. The ability to capture nonverbal, bodily reactions - such as tension, disdain, or rejection - provides deeper insight into how audiences actually process an advertising message. It is these reactions that allow us to better understand the level of implicit advertising literacy and its impact on brand trust.

The results of this study also offer an impetus to rethink traditional definitions of advertising literacy. They show that true understanding of advertising may take place at a level that respondents themselves are not aware of - and should therefore be complemented by the analysis of biometric and affective data.

For the Digital University itself, this means that the terms *MBA* and *online learning* require a new contextualising framework in which these benefits are emotionally legitimised. They may not be wrong - but they are communicated in a way that does not take into account the emotional map of the target audience.

This study was exploratory in nature, with a small research population (N = 19). Its aim was not to make statistical generalisations, but to highlight a conceptually important phenomenon - that the affective response of an audience can differ fundamentally from conscious evaluation. Future research could:

- validate the findings with a larger sample and more videos,
- To observe the long-term effects of affective mismatches in building brand loyalty,
- combine neuromarketing methods with deeper qualitative interviews to capture the full structure of affective-cognitive decision-making.

From an advertising literacy perspective, these findings remind us, despite the limitations of the study, that emotional response is also a form of evaluating advertising - and that the ability to perceive but not believe is increasingly common in the digital environment. Thus, we need to think of advertising literacy not only as a rational faculty, but also as a bodily filter that sorts between trust and distrust before conscious assent occurs.

Abstract

Research background: E-commerce has become an integral part of the business strategies of many global companies in recent years. The digitalisation of sales and marketing channels fundamentally changes how companies interact with customers, optimise their internal processes and expand into new markets. At the same time, e-commerce generates new challenges in logistics, legal regulation and customer behaviour that companies must face if they want to remain competitive in the global environment.
Purpose of the article: The article aims to analyse the importance of e-commerce in the context of global companies, focusing on its impact on business models, marketing strategies, customer behaviour and company performance. The article examines how digital transformation affects the functioning and success of multinational companies in different sectors of the economy.
Methods: The research is based on a qualitative comparative analysis of four case studies of successful multinational companies – Amazon, Zara (Inditex), IKEA and Nike. Thematic analysis of secondary data (scientific articles, annual reports, analytical studies) was chosen as the research method, which was coded and interpreted to identify common patterns and differences in implementing e-commerce.
Findings & Value added: The results confirm that e-commerce plays a strategic role in modern business models and contributes to increasing the performance of companies through better customer experience, efficient distribution and personalised marketing. Companies that have integrated e-commerce into their business achieve a higher rate of innovation, faster growth and better adaptation to global market changes. The article's added value is synthesising knowledge from different industries and formulating recommendations for companies that strive to digitise their operations in an international context successfully.

Keywords: E-Commerce, Global businesses, Business model, Marketing strategy, Customer behaviour

JEL classification: L81, M31, F23

1. Introduction

In the current digital era, electronic commerce (e-commerce) is becoming crucial for the functioning and development of global businesses. The development of information and communication technologies, especially the Internet, has fundamentally changed how companies interact with customers, suppliers and partners (Štefko, Nastišin, Nebeský & Fedorko, 2023). E-commerce has ceased to be just an additional sales channel and has become a strategic tool for competitiveness, expansion and innovation. The boundaries between the physical and digital worlds are increasingly blurred, and businesses that fail to adapt their models to digital reality risk losing relevance and market share (Chaffey, 2015; Vartiak, 2015). Global companies face a constantly changing environment that requires flexibility, efficiency and the ability to reach customers on different continents in real-time. E-commerce offers these advantages – it enables geographical expansion, personalisation of the offer, efficient logistics and data collection for strategic decision-making (Laudon & Traver, 2021). The importance of e-commerce has been further highlighted during the global COVID-19 pandemic, underscoring the vulnerability of traditional distribution channels and accelerating the digitalisation of many industries (UNCTAD, 2021).

E-commerce is business transactions over electronic networks, particularly the Internet (Kalakota & Whinston, 1997). It encompasses the purchase and sale of goods and services and marketing,

[*] Corresponding author: juraj.fabus@fpedas.uniza.sk

distribution, service and customer processes carried out electronically. As Schneider (2020) states, e-commerce includes B2C (business-to-consumer), B2B (business-to-business), C2C (consumer-to-consumer) and increasingly mobile (m-commerce) or social commerce.

With the growth of digitalisation, e-commerce has become a significant part of global business ecosystems. As Turban et al. note (2018), the development of technologies such as cloud computing, big data, artificial intelligence, and blockchain fundamentally affects the structure and functioning of e-commerce. These technologies enable process automation and a higher level of personalisation, security and transparency.

Global businesses use e-commerce as a key tool for entering new markets and optimising supply chains. As Kshetri and Dholakia (2014) point out, electronic platforms enable rapid and efficient expansion without requiring extensive physical infrastructure. Amazon, Alibaba, eBay and other global brands prove that a well-set e-commerce strategy can significantly contribute to the profitability and growth of a company.

Studies also point to the synergistic effect of e-commerce and internationalisation. For example, Sinkovics, Sinkovics and Jean (2013) showed that small and medium-sized enterprises (SMEs) can effectively overcome traditional barriers to entry into foreign markets through e-commerce. Adapting to local conditions, legislation, language, and culture requires sophisticated IT solutions and localisation strategies (Strauss & Frost, 2014; Rentková & Vartiak, 2017, Genzorová, Corejova & Stalmašeková, 2018).

E-commerce is changing the paradigm of marketing communication. In the online environment, digital marketing, especially search engine optimisation (SEO), content marketing, PPC campaigns, email marketing and social media marketing, is gaining importance (Vartiak, 2016; Chaffey & Ellis-Chadwick, 2019). Personalisation, dynamic pricing and retargeting allow companies to target customers highly.

Customer behaviour in the digital environment fundamentally differs from traditional shopping. The role of online reviews, ratings and so-called user-generated content is growing significantly. Customers expect a convenient shopping process, fast delivery, easy returns, and quality customer support (Laudon & Traver, 2021). According to Bhatti (2020), flexibility, accessibility, and personalisation are the main reasons customers prefer online shopping over physical stores.

Despite the advantages, e-commerce also brings several challenges. These include cyber threats, risks related to personal data protection, the need for digital skills and logistical problems in cross-border sales (OECD, 2020). Another critical aspect is regulation – global businesses have to face different legal frameworks and tax regulations in individual countries, which complicates the standardisation and scaling of solutions (Grewal et al., 2017; Konvit, Jasečková & Vartiak, 2023).

At the same time, there is an emphasis on sustainability – customers and investors increasingly expect online commerce to be environmentally responsible. This includes, for example, eco-friendly packaging, carbon-neutral delivery and ethical shopping (UNCTAD, 2021). These factors are also key in shaping long-term brand reputation and customer loyalty.

2. Methods

This article aims to analyse the significance of e-commerce in the context of global enterprises, emphasising its impact on business models, marketing strategies, customer behaviour, and firm performance. The research is based on a comparative analysis of selected case studies of multinational companies that have successfully integrated e-commerce into their operations. Given the complexity and multidimensionality of the research issue, a qualitative comparative case study analysis was chosen as the primary research strategy (Yin, 2018).

2.1 Research design

The article is based on a multi-case design, with each case study representing one global enterprise that has integrated e-commerce into its business model. This approach allows for an in-depth analysis of real digitisation processes and enables the identification of standard features, patterns, and differences between companies operating in different industries.

2.2 Case study selection

Based on theoretical criteria and the availability of secondary data, four multinational companies with a significant e-commerce presence were selected:

- **Amazon** – a technology platform and global leader in online sales,
- **Zara (Inditex)** – a fashion brand with a strong omnichannel strategy,
- **IKEA** – a global furniture retailer with a hybrid online-offline model,
- **Nike** – a sports brand with an innovative approach to digital marketing and mobile sales.

These companies were selected to represent different industries (technology, fashion, furniture, sports), ensuring the findings' contextual variability and broader generalizability.

2.3 Data collection

Data collection was carried out through secondary research, i.e. analysis of existing data sources, which included:

- annual reports and official documents of companies,
- scientific and professional articles published in the Web of Science, Scopus and Google Scholar databases,
- case studies from renowned research institutions and universities (e.g. Harvard Business School),
- reports from international organisations (e.g. OECD, UNCTAD),
- media and analytical outputs from renowned portals (e.g. Statista, McKinsey, Deloitte).

These sources were chosen for their reliability, timeliness and analytical value, with emphasis on documents published after 2018 to reflect the latest developments in the field of e-commerce.

2.4 Analytical method

Thematic analysis (Braun & Clarke, 2006) was used to process the data, which allowed for the systematic identification, analysis and interpretation of key themes within the individual case studies. The analysis process proceeded in the following steps:

1. **Data coding** – identification of relevant passages in the texts that relate to the main research dimensions (business model, marketing strategy, customer behaviour, performance),
2. **Categorisation** – grouping codes into higher thematic units according to standard features,
3. **Comparison** – comparing findings across individual cases to identify patterns, differences and potential causal connections,
4. **Interpretation** – linking empirical findings with a theoretical framework and formulating conclusions.

The analysis results are presented as synthesised findings that connect individual cases into a common analytical core and answer the main research question: What is the significance of e-commerce in global enterprises, and how does it affect their business functioning?

2.5 Research limitations

Despite the emphasis on thoroughness and systematicity, there are certain limitations of the research that need to be mentioned:

- Due to the orientation towards qualitative analysis, the aim was not to quantify the exact impact of e-commerce on firm performance but rather to understand the mechanisms and processes that lead to this impact.
- The selection of firms was targeted and not random, which may limit the generalizability of the findings to all firms.
- Secondary data depends on the transparency and availability of published information, and not all firms publish detailed data on e-commerce activities.

Despite these limitations, the methodology allowed for deep insight into the practical integration of e-commerce in the global business environment and offered valuable insights for research and management practice.

3. Results

This article analysed four case studies of multinational companies – Amazon, Zara (Inditex), IKEA and Nike – that are implementing e-commerce as a strategic part of their business. The analysis focused

on identifying the impact of e-commerce on their business models, marketing strategies, customer behaviour and overall performance. Each case provided specific insights that can be generalised to a broader range of global businesses.

3.1 Business model transformation

The analysis results show that e-commerce has fundamentally transformed traditional business models into customer-centric and digital-centric models. Amazon represents a paradigmatic example of a platform business model, where e-commerce is the structure's central pillar. The company sells its products and provides space for other sellers, thereby creating network effects and a large-scale digital economy (Laudon & Traver, 2021).

Similarly, Zara has expanded its fast fashion model to include digital elements – customers can track product availability online, create personalised collections, and order goods with home or brick-and-mortar delivery. In this way, Zara has connected the brick-and-mortar and online worlds into an omnichannel model, thereby increasing efficiency and customer satisfaction (Fernie & Sparks, 2019).

The results show that companies that could connect physical and digital infrastructure saw increased revenues, shortened delivery times, and higher customer retention. However, this shift required significant technological, logistics, and data analytics investments.

3.2 Innovations in marketing strategies

Marketing in the e-commerce environment has proven to be a key factor in the success of the analysed companies. For example, Nike uses advanced personalised marketing built on data from mobile applications, websites, and social media. Customers receive individual recommendations, discounts, and content, which increases their engagement and loyalty (Chaffey & Ellis-Chadwick, 2019).

IKEA has also innovated in content marketing, investing heavily in augmented reality (AR) and visualisation tools. Customers can use a mobile app to see how furniture will look in their interior, which increases confidence in their purchasing decisions. IKEA has also optimised its e-commerce campaigns for different regions and cultures, effectively lowering barriers to entry into new markets.

The comparison showed that effective e-commerce marketing strategies must be built on data, localisation, automation and omnichannel integration. Companies focusing exclusively on pricing or mass communication without segmentation did not achieve such significant performance improvements.

3.3 Impact on customer behaviour

E-commerce has significantly influenced customer expectations and behaviour, with customers of the analysed companies demonstrating a higher level of digital literacy, demands for quality of service and the need for a personalised experience. In the case of Amazon, it turned out that the key factors of customer satisfaction are speed of delivery, ease of purchase and transparency of product information.

The results show that customers actively search for reviews, compare prices and expect quick communication with customer support, ideally via chatbots or live chats. These elements were effectively deployed within the e-commerce platforms of Nike and Zara, which led to a reduction in the number of complaints and an increase in the conversion rate.

An interesting result was provided by IKEA, showing that customers use e-commerce mainly as an information tool before visiting the store. This hybrid model, ROPO (research online, purchase offline), emphasises optimising online channels for offline sales. E-commerce is, therefore, not only a substitute for brick-and-mortar sales but also acts as a complement to brick-and-mortar sales.

3.4 Impact on business performance and growth

All companies analysed have seen a positive impact of e-commerce on their performance, which has been reflected in increased sales, reduced costs, and expanded customer base. As a purely digital platform, Amazon has achieved a dominant position in the global market thanks to e-commerce. At the same time, its innovative solutions (e.g. predictive logistics subscription services) ensure a high rate of repeat purchases (Laudon & Traver, 2021).

In 2022, Nike announced that more than 40% of its sales come from digital sales channels, with the SNKRS mobile application becoming the primary distribution tool for special editions and collectable models. Zara saw more than 75% year-on-year growth in e-commerce sales during the pandemic, with its

online-offline combination strategy giving the company an advantage over competitors that relied solely on brick-and-mortar stores.

IKEA has seen the most significant shift in distribution efficiency – optimising e-commerce warehouses and new pickup locations has reduced logistics costs by approximately 12% over two years. In addition, e-commerce has enabled the collection of valuable data on customer preferences, which is used in the design of new products and marketing campaigns.

3.5 Summary of findings

Based on the comparative analysis, it can be concluded that:

- E-commerce is an integral part of the business models of successful global companies and plays a decisive role in internationalisation.
- Implementing e-commerce requires advanced technological solutions, the ability to process data efficiently and a high degree of adaptability in marketing communication.
- Customers expect a simple, fast and personalised shopping experience, which places high demands on UX, logistics and customer support.
- All analysed companies have seen a positive impact on performance, mainly in sales growth, increased customer loyalty and expansion into new markets.

These results confirm the hypothesis that e-commerce represents a strategic tool for competitiveness in the global business environment.

4. Discussion

The results show that e-commerce has become essential to global companies' business strategies. This fact is consistent with previous findings by several authors who claim that digital transformation is one of the key drivers of growth and innovation in the global economic environment (Chaffey, 2015; Laudon & Traver, 2021). Studies of Amazon, Zara, Nike and IKEA show that e-commerce is not just an additional sales channel but the core of a comprehensive digital strategy that goes beyond individual departments' boundaries and affects all business components. The results confirm that successful companies apply an integrated approach to e-commerce, which is linked to the business model and marketing, thus reflecting the concept of omnichannel strategy (Verhoef et al., 2015). E-commerce is not an isolated activity but an intersection between technology, logistics, customer experience and strategic management. This corresponds to the model of the digital business ecosystem, in which companies act not only as sellers but also as intermediaries, innovators and service providers (Turban et al., 2018).

An interesting finding is that e-commerce is not always just a substitution for traditional channels. In the case of IKEA, the so-called ROPO effect (Research Online, Purchase Offline) was evident, confirming the need to synchronise online and offline elements of the sales process. This finding is in line with the research of Frasquet et al. (2015), who claim that customers often use digital tools to obtain information but purchase themselves physically.

The findings suggest several practical recommendations for businesses that want to expand their e-commerce activities in a global context:

1. **Invest in technology and data analytics:** In the case of studies, successful companies use advanced tools for data collection and analysis, which allows them to understand customer needs better, optimise marketing campaigns and increase operational efficiency. Businesses that ignore this ability risk losing their competitiveness.
2. **Localisation and cultural adaptation:** Successful global e-commerce strategies require adapting the product portfolio, website design, language mutations, and delivery and payment methods to specific markets. A one-size-fits-all approach proves ineffective in a global environment (Sinkovics et al., 2013).
3. **Flexible logistics:** Fast and reliable delivery is one of the main competitive advantages of e-commerce. Companies like Amazon or Zara invest in automated warehouses, predictive supply, and local distribution centres, thereby reducing costs while increasing customer satisfaction (Fernie & Sparks, 2019).
4. **Customer experience and UX design:** An e-commerce platform must be intuitive, responsive, and optimised for different devices. In addition, customers expect a high level of personalisation and

the possibility of immediate feedback. These aspects have a direct impact on conversion rates and repeat purchases.

Despite its many advantages, implementing e-commerce is not without risks. A significant challenge is cybersecurity, especially protecting personal data and financial transactions. Cyberattacks increasingly target global businesses, which requires a robust IT infrastructure and constant threat monitoring (OECD, 2020).

Another problem is the complexity of the legal and tax environment in different countries. Globally operating companies have to face several regulations related to consumer protection, electronic signatures, invoicing and VAT. This complicates the standardisation of processes and increases the administrative burden (Grewal et al., 2017).

Last but not least, the sustainability of e-commerce is also a challenge. Although electronic sales can reduce the need for physical stores, it also generates new environmental burdens – packaging, transport, and returns. Consumer pressure for environmentally responsible solutions is growing, and companies must reflect this trend in their strategies (UNCTAD, 2021).

This article contributes to expanding knowledge about e-commerce in the context of global business strategies. Unlike many previous studies that focused only on the technical side of e-commerce, this research highlights its holistic impact on business model, marketing and performance. It also emphasises the importance of the interaction between online and offline channels and the need to integrate them into a unified strategy.

The comparative analysis of real case studies provides valuable empirical knowledge that can serve as a reference framework for future research in digital transformation, customer behaviour in e-commerce or internationalisation of business through digital channels.

Conclusion

Electronic commerce has become one of the most critical factors shaping the global business environment in recent decades. The results of this article demonstrate that e-commerce is no longer just an additional sales tool but a key element of the strategic management of global companies, influencing business models, marketing strategies, customer behaviour and overall business performance.

Based on a comparative analysis of selected multinational companies (Amazon, Zara, IKEA, Nike), it can be concluded that successful e-commerce implementation requires a comprehensive, integrative approach that includes technological innovation, consistent customer orientation, supply chain optimisation and effective use of data. These companies have demonstrated the ability to adapt their business models to the dynamic digital environment, achieving significant competitive advantages.

The key success factors in e-commerce have been shown to be:

1. the ability to connect online and offline environments (omnichannel),
2. the use of personalised marketing and content tailored to specific market segments,
3. fast and flexible logistics as a tool for maintaining customer satisfaction,
4. and the emphasis on analysing customer behaviour through digital tools.

At the same time, the article also pointed out several challenges associated with implementing e-commerce, such as problems with cybersecurity, legal regulation in different countries, logistics capacities or the environmental impacts of digital sales. These factors require systematic risk management and a long-term strategic vision.

From a scientific point of view, this work contributes to expanding knowledge about the impacts of e-commerce on global businesses. It confirms the need for further research in this area. Future research could focus on:

1. the effect of e-commerce on sustainability and the environmental footprint of businesses,
2. comparing e-commerce approaches across sectors (e.g. manufacturing vs. services),
3. and studying e-commerce in the context of developing countries and their specific conditions.

In conclusion, e-commerce is no longer just a technological trend but a systemic element of the modern global economy, shaping how companies sell and think about innovation, customer relationships and the sustainability of their business. For businesses that want to succeed in the digital age, e-commerce is an option and a necessity.

Visual and Psychographic Features of Advertising Creatives as Predictors of User Attention on the Meta Platform

***Igor* Fedorko**[1,*]

[1] University of Prešov in Prešov, Department of Marketing and International Trade, Faculty of Management and Business, Konštantínova 16, 080 01 Prešov, Slovakia

Abstract

Research background: In highly saturated digital environments like Meta platforms (Facebook and Instagram), user attention is a scarce resource. The effectiveness of video advertising increasingly depends on creative elements that can capture and retain viewer attention. Prior research has suggested that emotional tone and brand presentation may significantly influence user engagement, yet empirical validation using behavioral metrics remains limited.
Purpose of the article: This study aims to examine how selected visual and psychographic features—specifically emotional tone and brand visibility—affect user attention in video ads. Attention is operationalized through the *15s_views_rate* metric, which reflects the percentage of impressions in which users viewed at least 15 seconds of a video, commonly used as a proxy for brand awareness.
Methods: A multiple linear regression analysis was conducted on a manually coded dataset of 20 video ads from a luxury watch brand campaign on Meta platforms. Key creative variables were coded based on predefined criteria and tested as predictors of *15s_views_rate*. Variables were standardized, and diagnostic checks were performed to ensure model validity.
Findings & Value added: Although the hypotheses were not statistically confirmed, results showed a positive directional effect for emotionally framed ads and a negative effect of overt brand visibility on sustained user attention. These findings demonstrate that behavioral metrics like *15s_views_rate* can be effectively used to model user response, even with a small sample. The study contributes to the growing body of research on data-driven creative optimization and highlights practical considerations for ad design in attention-driven media environments.

Keywords: User attention, Visual features, Psychographic attributes, Advertising creatives, Social media

JEL classification: M37, D91

1. Introduction

In the context of digital advertising on platforms such as Meta, the ability to capture and sustain user attention is a critical determinant of success. The fast pace of content consumption and the highly visual nature of these platforms underscore the importance of creative elements in advertising. This chapter therefore examines how visual and psychographic features influence user attention and engagement.

1.1 Attention and Engagement on Social Media: The Role of Visual Elements in Online Advertising

In the social media environment, where users scroll through vast amounts of content within seconds, attention and engagement have become key indicators of advertising effectiveness. These two concepts are closely interconnected: while attention represents the initial cognitive step in processing an advertisement, engagement reflects a deeper emotional and behavioral involvement of the user.

As noted by Schivinski et al. (2022), engagement on social media is a multidimensional phenomenon—encompassing cognitive (attention, awareness), emotional (experience, affinity), and

* Corresponding author: igor.fedorko@unipo.sk

behavioral responses (interactions such as likes, comments, shares). Similarly, Voorveld et al. (2018) show that the type of social platform influences which of these dimensions dominates—for instance, Instagram tends to foster emotional engagement, while text-based platforms promote more cognitive responses. Engagement should therefore not be viewed as a single metric, but rather as a set of reactions whose intensity and form depend on the platform environment and the type of content.

Kadhim and Ozuem (2020) demonstrated that engagement—whether measured through interactions or attention tracking—is significantly influenced by the visual elements of an advertisement, such as color, typography, composition, and overall design. Their predictive analysis of Instagram campaigns showed that visually compelling ads generated higher levels of user engagement.

Other studies likewise suggest that the appearance of the creative is often a decisive factor in whether a user notices the advertisement at all. Müller and Christandl (2021) identified several design elements that increase an ad's ability to capture and hold attention, including contrast, clear visual hierarchy, a dominant central object, and subtle motion. Their research also highlights the risk of visual overload, which can overwhelm the user's senses and diminish the effectiveness of the communication.

From a psychological perspective, the social context of an advertisement is also crucial. Smitshuijzen et al. (2020) found that ads containing social cues—such as information that the product is liked by a friend—enhance message credibility and strengthen emotional connection with the brand. This effect may be particularly relevant in video advertising, where associations and subconscious perception can quickly influence a user's decision to pay attention.

Openness to experience has been identified as the most consistent personality predictor of artistic preferences, suggesting that similar psychographic traits may also influence which visual advertisements users are likely to notice (Chamorro-Premuzic et al., 2009). Individuals with a strong tendency toward sensation-seeking and higher psychoticism scores often prefer visually intense or "unpleasant" visuals—potentially explaining their different reactions to emotionally charged advertisements (Rawlings, 2003).

On the other hand, Masłowska, Ohme, and Segijn (2021), in an eye-tracking study, showed that visual attention is not always affected by recommendation content or device type (mobile vs. desktop). Their experiment conducted in a realistic newsfeed environment demonstrated that the primary determinant of user attention remains the visual design of the ad itself.

These findings suggest that in the context of digital advertising—particularly on visually driven platforms like Meta—the form and visual execution of the creative play a fundamental role in capturing and retaining user attention.

1.2 Psychographic Features, Emotional Tone, and Video Advertising on the Meta Platform

When creating video advertisements on the Meta platform (Facebook and Instagram), it is essential to consider not only the demographic profile of the target audience but especially psychographic attributes such as personality traits, values, preferred communication style, and users' emotional predispositions. These factors fundamentally influence attention, emotional engagement, and ultimately the memorability of the ad.

Advertising campaigns that account for the psychographic characteristics of the audience tend to achieve higher effectiveness. As early as Boote (1982–1983) pointed out, psychographic segmentation is particularly critical in multinational campaigns, as value-based preferences can vary significantly even among seemingly similar target groups. Ignoring these differences during data aggregation may lead to inaccurate or misleading conclusions. This principle remains relevant today—especially in the context of social media ad formats, where it is crucial to evoke user identification with the content through carefully selected emotional tone, music, storytelling, and visual style.

Recent advances in psychographic segmentation have introduced new possibilities for identifying these traits without relying on traditional surveys. Pitt, Bal, and Plangger (2020) demonstrated that the language consumers use when spontaneously describing their experiences can reveal personality traits such as extraversion, openness, or emotional stability. These insights—obtained, for example, from reviews or social media posts—enable advertisers to craft more targeted creatives, not only based on demographics but also on the "real" psychological disposition of the

audience. This opens new opportunities for platforms like Meta, where a personalized emotional tone in video ads can influence user response within the first few seconds of playback.

The language consumers use reflects not only their personality traits but also their degree of authenticity and emotional connection, which can serve as an important guide for crafting genuine advertising messages on social media (Pennebaker et al., 2003). The words people use in online comments or reviews can be analyzed to reveal personality traits such as extraversion or neuroticism—unlocking new opportunities for personalizing video advertisements without relying on traditional surveys (Fast & Funder, 2008; Hirsh & Peterson, 2009).

From the perspective of emotional impact, Poels and Dewitte (2019) emphasize the importance of emotional dimensions such as pleasure, arousal, and dominance. These dimensions affect how a creative is perceived—for instance, higher levels of arousal can increase viewer attention and enhance message recall. Therefore, in video content on Meta, it is not enough to simply choose a "positive" or "negative" emotion—what matters is the intensity and timing of the emotional experience within the ad.

Similarly, Teixeira, Wedel, and Pieters (2012) highlight the critical role of emotions like surprise and joy in sustaining attention in online video advertising. Their research shows that the degree of surprise effectively captures attention, while the speed at which joy builds is key to keeping viewers engaged. This implies that advertisers on Meta should deliberately design the emotional trajectory of their videos—how emotions evolve and intensify throughout the spot. Well-paced emotional structuring can increase not only the likelihood of surpassing the 15-second view threshold (often used as a proxy for brand awareness) but also the overall impact of the advertisement.

2. Conceptual Framework and Hypotheses Development

Attention is one of the key factors influencing advertising effectiveness, particularly in environments saturated with digital content, where users are constantly exposed to competing visual stimuli (Pieters & Wedel, 2004). On platforms such as Meta (Facebook and Instagram), where consumers scroll at high speed and make intuitive decisions within milliseconds, an advertisement's ability to retain attention is a critical prerequisite for building brand awareness.

One of the most widely used indicators in advertising analytics is the 15-second video view metric—that is, the percentage of impressions in which the user watched a video for at least 15 seconds. This standardized metric is available within the Meta Ads interface and is commonly used as a proxy for attention retention and potential user engagement. Oğuz et al. (2023) point out that viewing duration may be a more robust measure than raw impression counts, as it better reflects the level of user involvement and the creative's ability to stand out in a visually competitive environment.

Previous research suggests that attention in video advertising is shaped by a combination of psychographic and visual elements—including emotional tone, rhythm and pacing, music selection, color, and brand visibility (Rasheed, Sheikh, & Shah, 2005; Oğuz et al., 2023). These features have been shown to predict not only subjective engagement but also objectively measurable behaviors such as view duration and interaction rates. While some studies rely on automated extraction of low-level features, others employ manually annotated creative characteristics, which can more precisely capture the psychological and communicative context of the ad's execution.

Our study builds on these insights by testing the impact of manually coded visual and psychographic attributes of video advertisements on the 15s_views_rate metric. We use this measure as a quantitative proxy for user attention allocated to advertising content. Based on the theoretical framework and preliminary data exploration, we propose the following hypotheses:

H1: Video ads with an emotional tone will exhibit a statistically significantly higher 15s_views_rate compared to product-focused video ads.

H2: Ads in which the brand is visually present from the beginning of the video will achieve a higher 15s_views_rate compared to those where the brand appears only at the end or is entirely absent.

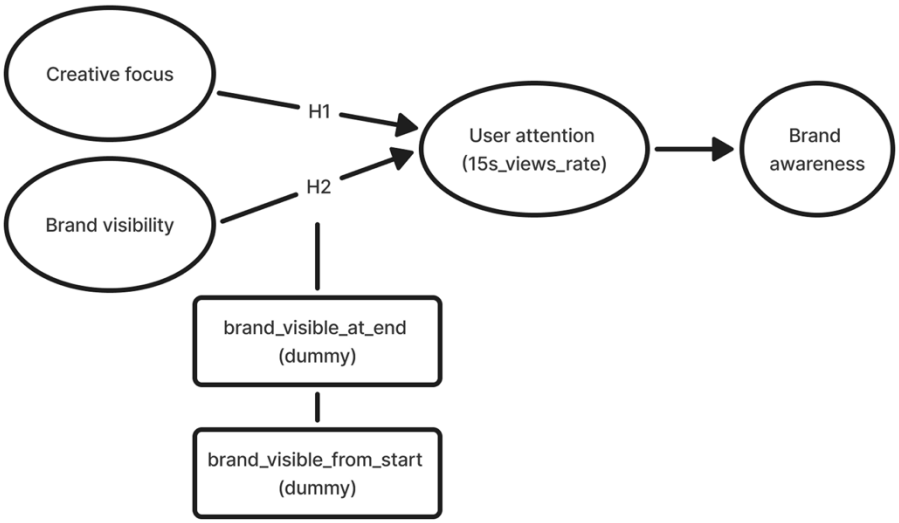

Figure 1. Conceptual model: Predictors of brand awareness via user attention (15s view rate)
Source: own processing (2025)

3. Methodology

3.1 Research Design

The study is designed as an exploratory analysis of a small sample of video advertisements, aiming to test the applicability of behavioral metrics (e.g., *15s_views_rate*) in predicting user attention based on creative features. The objective is also to assess whether a simple manual coding framework of visual and psychographic attributes can serve as a reliable foundation for quantitatively modeling user responses to video advertising in the real-world context of social media platforms.

3.2 Data Set

The analysis is based on performance data from 20 unique video advertisements created as part of brand awareness campaigns for a luxury watch brand. All videos were deployed via the Meta platform (Facebook and Instagram) and targeted a Slovak audience. The ads generated over 2.4 million impressions in total, reaching more than 1.3 million unique users. The sample includes videos of varying lengths and styles, ensuring variability within the dataset.

Additional statistics: Total number of 15-second video views: over 190,000; Total watch time beyond 15 seconds: approximately 791 hours; Average *15s_views_rate*: 7.5%; Range across videos: from 1.7% to 13.9%.

3.3 Variables and Coding

Each video was manually analyzed and coded based on predefined criteria. During the coding process, several practical dilemmas emerged, which were addressed by simplifying certain variables:

Ad focus (creative_focus): Originally, three categories were distinguished—product-focused, lifestyle-oriented, and status-driven videos. However, in practice, the distinction between lifestyle and status proved ambiguous, as both often employ similar visual elements and emotional framing. Therefore, a binary coding scheme was adopted: 0 = product-focused video (e.g., “hands-on” shots emphasizing functionality or detail), 1 = emotionally driven video (e.g., storytelling, metaphor, lifestyle scenes, or characters).

Brand visibility (brand_visibility): This variable captures when the brand is visually presented in the video: 0 = brand is absent, 1 = brand appears only at the end of the video, 2 = brand is visible from the beginning.

For the regression analysis, this three-level ordinal variable was transformed into two binary (dummy) variables: brand_end = 1 if the brand appears only at the end; brand_start = 1 if the brand is visible from the beginning. The reference category comprises videos in which the brand is entirely absent. This approach allows for more flexible hypothesis testing (H2) without assuming equidistant effects between all three levels of visibility.

3.4 Dependent Variable – *15s_views_rate*

As the primary dependent variable, we selected the 15s_views_rate metric, defined as the proportion of impressions in which a user watched the video advertisement for at least 15 seconds. This metric is calculated as follows: *15s_views_rate = (views_15s / impressions) × 100*. It represents a standard behavioral metric in Meta Ads analytics for campaigns aimed at building brand awareness.

The rationale for using this metric is as follows: Relevance to the research objective: Given that the campaign objective was to increase brand awareness, longer ad viewing duration (at least 15 seconds) is considered an indicator that the advertisement captured the user's attention sufficiently to retain their interest. The metric thus serves as a proxy for attention, which we consider a necessary intermediate step in the brand awareness formation process. Stability compared to other metrics: As highlighted by Aslan Oğuz et al. (2023), duration-based metrics are less susceptible to random fluctuations and often correlate more strongly with user engagement than impression counts or 3-second view thresholds. Availability and consistency: Unlike declarative indicators (e.g., post-test brand recall surveys), 15s_views_rate is readily available for every video, generated directly by the platform, and does not require additional research instrumentation. This makes it an ideal dependent variable for modeling the effect of creative features in large-scale datasets.

Methodological simplicity and comparability: The value is expressed as a percentage, allowing for direct interpretation and comparison across different creatives without the need to standardize by reach or frequency. For these reasons, we consider 15s_views_rate the most appropriate metric for this exploratory analysis of the relationship between visual and psychographic features of video ads and user attention.

Table 1. Operational Definitions of the Variables Used in the Model

Variable	Type	Definition
15s_views_rate	Continuous	Percentage of ad impressions that resulted in at least 15 seconds of continuous video view.
creative_focus	Binary (0/1)	Binary variable: 0 = product-focused ad (hands-on), 1 = emotionally driven ad (storytelling, lifestyle).
brand_visibility	Ordinal (0–2)	Ordinal variable: 0 = brand absent, 1 = brand visible only at the end, 2 = brand visible from the beginning.
brand_visible_at_end	Dummy (0/1)	Dummy variable: 1 if brand is only shown at the end of the video, 0 otherwise.
brand_visible_from_start	Dummy (0/1)	Dummy variable: 1 if brand is shown from the beginning of the video, 0 otherwise.

Source: Own coding and processing based on Meta Ads performance data (2024).

3.5 Analytical Procedure

The relationship between the selected independent variables and user attention was examined through a multiple linear regression analysis. The model was constructed to predict user attention, operationalized by the *15s_views_rate* metric, based on key visual and psychographic features of each ad. The regression equation was specified as follows:

$$\text{15s_views_rate}_i = \beta_0 + \beta_1 \cdot \text{creative_focus}_i + \beta_2 \cdot \text{brand_visible_at_end}_i + \beta_3 \cdot \text{brand_visible_from_start}_i + \varepsilon_i$$

The input variables were standardized and screened for the presence of extreme values. Multicollinearity among predictors was low, and the assumptions of linearity and normality of residuals were verified using diagnostic plots. Given the sample size (n = 20), the results are interpreted as preliminary and primarily serve to test the applicability of the methodology and the formulation of hypotheses for future research on a larger sample. All calculations were performed in Python 3.11 using the pandas, statsmodels, and matplotlib libraries.

4. Results

4.1 Descriptive Statistics

The average *15s_views_rate* across all video ads was 7.55% (SD = 2.90), with individual values ranging from 1.68% to 13.88%. Emotionally driven ads achieved a higher mean view rate (9.04%) compared to product-focused ads (6.95%), although this difference is not statistically significant at this stage. The sample included 12 product-focused and 8 emotionally driven ads. Regarding brand visibility, 4 ads did not display the brand at all, 5 showed the brand only at the end, and 11 featured the brand from the beginning of the video.

Table 2. Results of the Multiple Linear Regression Model Predicting 15s Video View Rate

Variable	Coefficient (β)	p-value	Interpretation
Intercept	10.16	0.000	Baseline view rate for a product-focused ad with no brand
creative_focus	+2.09	0.318	Emotional ads ↑ by 2.09% on average (not significant)
brand_visible_at_end	−5.49	0.068	Brand shown only at end ↓ by 5.49% (marginally significant)
brand_visible_from_start	−3.33	0.104	Brand shown from beginning ↓ by 3.33% (not significant)

Notes: The overall model explained 21.9% of the variance in 15s_views_rate ($R^2 = 0.219$).
Source: Author's calculations based on Meta Ads campaign performance data (2024).

4.2 Hypotheses testing

The coefficient for the variable creative_focus (coded as 0 = product-focused ad, 1 = emotionally driven ad) was positive (β = 2.09), aligning with Hypothesis H1, which predicted a higher attention retention rate for emotionally driven creatives. Although the difference between the groups was quantitatively noticeable (mean 15s_views_rate for emotional ads = 9.04%, for product-focused ads = 6.95%), this effect did not reach statistical significance (p = 0.318). Therefore, H1 cannot be statistically supported; however, the direction of the coefficient and the difference in means suggest a potential practical effect that merits further investigation with a larger sample.

The coefficients for the brand visibility variables—brand_visible_at_end (β = −5.49) and brand_visible_from_start (β = −3.33)—were negative, contradicting Hypothesis H2, which assumed a positive impact of early brand presence on attention retention. For ads where the brand appeared only at the end, the effect was nearly statistically significant (p = 0.068), suggesting that explicit brand presence—especially when introduced at the end of the video—may negatively affect an ad's ability to retain attention. The coefficient for brand visibility from the beginning (p = 0.104) also did not reach statistical significance, though the effect followed a similar negative trend. Based on these results, H2 is not supported.

These findings open the door for further discussion around concepts such as brand aversion or ad-skipping behavior, where strong identification of content as advertising may reduce user attention (see Rasheed et al., 2005; Aslan Oğuz et al., 2023). It is also possible that videos without explicit branding appeared more authentic or narrative-driven (i.e., "native-like content"), which may have contributed positively to viewer retention.

The overall model explains 21.9% of the variance in the dependent variable 15s_views_rate ($R^2 = 0.219$), which is a relatively acceptable level of explained variance for behavioral data, especially given the strong influence of contextual factors, platform algorithms, and creative quality.

Although neither of the tested hypotheses reached statistical significance at conventional levels, the directionality of the effects offers several important insights:

Emotionally framed videos may enhance attention retention, in line with assumptions of behavioral psychology and prior findings on the impact of storytelling in advertising.

Strong brand visibility, paradoxically, showed a negative relationship with attention retention, suggesting that overt branding may reduce user engagement.

The results underscore the importance of balancing brand identifiability with narrative style—especially in digital environments where users make decisions about content engagement in a matter of seconds.

These findings are preliminary and limited by the sample size (n = 20), but they demonstrate the practical applicability of behavioral metrics such as 15s_views_rate as a valuable tool for evaluating creative effectiveness. To confirm and generalize the observed effects, further research with larger and more diverse datasets is required.

5. Discussion

This pilot study focused on analyzing the relationship between selected visual and psychographic features of video advertisements and the level of user attention on Meta platforms. While the results did not provide statistically significant evidence to support the formulated hypotheses, they offer several important insights and observations that may inform both future research and the practical development of advertising creatives.

One of the most notable findings is the indicated positive effect of emotional framing on view rates, which aligns with prior research on affective media processing (e.g., Pieters & Wedel, 2004). Although this effect did not reach statistical significance, the difference between groups was relatively substantial (approximately +2%), suggesting the potential of creatives that employ storytelling, metaphor, or lifestyle elements to enhance user engagement.

In contrast, the presence of branding within the video—whether from the beginning or only at the end—showed a negative relationship with the 15s_views_rate. This finding contradicts certain marketing recommendations that emphasize early brand visibility. In the context of behaviorally oriented campaigns, this may indicate that users are more likely to skip or ignore content that is immediately identifiable as advertising—a phenomenon related to concepts such as banner blindness or ad fatigue. Interestingly, ads without visible branding had the highest average view rates, which may reflect the effectiveness of native-like or "organic" creatives that do not trigger immediate resistance.

At the level of the research framework, the study confirms that 15s_views_rate can serve as a pragmatic indicator of attention, suitable for quantitative modeling of user behavior in digital environments. Moreover, the findings suggest that manually coded formal features of video ads—such as emotional tone and brand visibility—can be successfully applied in predictive modeling, even with a relatively small sample.

However, these results must be interpreted in light of the study's limitations: the sample consisted of only 20 ads from a single brand in the luxury watch segment; variables were coded subjectively, albeit based on predefined criteria; and the model did not account for other influential factors such as target audience characteristics, creative quality, ad placement, or time of day.

5.1 Practical Implications

For advertisers, creative teams, and digital strategists, this study offers several actionable recommendations. Emotional framing and narrative elements may foster greater user interest than explicit product demonstrations—particularly in brand awareness campaigns. Branding should not be assumed to be inherently beneficial; overly early or overt brand presence may reduce attention, especially when users quickly recognize the content as an advertisement.

Analyzing creative features through behavioral metrics such as *15s_views_rate* provides an accessible and practical method for campaign optimization without the need for post-test surveys. The findings also highlight the importance of testing multiple creative variants (e.g., A/B testing), particularly when it comes to brand visibility and the tone of communication.

5.2 Limitations and Directions for Future Research

This study presents several methodological and contextual limitations that must be considered when interpreting the results. First and foremost is the limited sample size—the analysis was based on data from only 20 video advertisements, all of which were part of campaigns for a single brand in the luxury goods segment. This constraint reduces the statistical power of the tests and prevents the formulation of generalizable conclusions across industries. Moreover, the specific visual identity and target audience of a luxury watch brand may influence user behavior differently than mass-market products, services, or brands with markedly different communication strategies.

Another limitation lies in the manual coding of ad features such as emotional tone and brand visibility. Despite the use of predefined categories and efforts to ensure consistency, this process remains partly subjective. Future studies should consider verifying coding reliability through multiple independent

raters (inter-rater reliability) or employing automated tools for extracting visual characteristics from video content. The current model also did not account for broader contextual variables in which the ads were displayed—such as placement (feed vs. stories), time of exposure, video length, or qualitative aspects like editing rhythm, character presence, or language.

Despite these limitations, the results suggest that behavioral metrics like 15s_views_rate have strong potential as valuable tools for assessing creative effectiveness, particularly in brand-focused campaigns. Future research should aim to replicate the study on a larger and more diverse sample of video ads from various sectors and platforms. It is also advisable to expand the set of predictors to include additional visual, audio, and narrative features, and to enrich the models with contextual variables related to platform dynamics and audience behavior. From a methodological perspective, there is room for applying more advanced analytical techniques, including machine learning, as well as for experimentally testing the effects of specific creative adjustments through A/B testing. Combining behavioral data with physiological measures (e.g., eye-tracking or biometric feedback) could further deepen our understanding of visual attention processes in digital advertising environments.

Conclusion

This study examined the relationship between visual and psychographic features of video advertisements and user attention on Meta platforms. Using multiple linear regression, we tested the impact of emotional tone and brand visibility on the 15-second view rate (15s_views_rate), which served as a proxy metric for attention retention and, indirectly, brand awareness. Although the tested hypotheses were not statistically confirmed, the results indicated a positive directional effect for emotionally driven ads and a negative relationship between explicit branding and view rates. These findings suggest that even with a limited number of ads, behavioral metrics can be used to identify patterns that may help optimize creative performance. Moreover, the study demonstrated that 15s_views_rate is a practically applicable indicator of attention that can be effectively modeled based on observable features of the video.

Abstract

Research background: The study explores the impact of emotional factors on consumer purchasing decisions in the context of e-commerce. Recent scientific findings emphasise that emotions influence not only purchase intent but also the overall decision-making process, often preceding conscious rational evaluation.
Purpose of the article: The aim was to analyse the emotional factors influencing consumer buying behaviour in the e-commerce environment through a secondary analysis of available academic literature. Special attention was given to the role of neuromarketing methods in identifying and interpreting emotional responses.
Methods: By conducting a secondary analysis of eight scientific studies published between 2021 and 2024, the most common emotional stimuli and their influence on purchase intent were identified.
Findings & Value added: The findings show that emotions such as trust, excitement, and a sense of urgency can mediate the relationship between marketing stimuli and the consumer decision-making process. Elements such as reviews, discounts, and live-streaming interactions also play a significant role. Additionally, visual, auditory, and interactive elements in digital environments were found to enhance emotional engagement and customer loyalty. Neuroscientific methods (EEG, eye-tracking, FACS) have proven to be practical tools in examining these processes. The study underlines the importance of personalised, emotionally driven marketing strategies based on real-time consumer feedback.

Keywords: Emotional factors, Purchase behaviour, E-commerce

JEL classification: M31, L81

1. Introduction

Neuromarketing represents the intersection of neuroscience and marketing, examining the neural and psychological processes of consumers to understand their purchasing decisions better (Janiga, 2021).

Professor Ale Smidts was the first to use the term neuromarketing in 2002. He defined neuromarketing as a field concerned with analysing the brain processes that explain customer behaviour in purchasing situations (Iloka and Onyeke, 2020). In other words, the goal of neuromarketing is to examine the processes that occur in consumers' minds when they are exposed to marketing stimuli, such as advertisements, product packaging, or websites, and how these stimuli subsequently influence their purchasing behaviour. In terms of the impact of neuromarketing on customer behaviour, it is important to note that, as early as the beginning of the 21st century, Zaltman (2003) pointed out that up to 95% of our purchasing decisions occur in the subconscious.

Neuromarketing seeks to mitigate uncertainty in marketing decisions by utilising objective neuroscientific data, rather than relying on traditional surveys that rely on subjective responses from respondents. Neuromarketing uses methods such as functional magnetic resonance imaging (fMRI), electrocardiogram (ECG) measurements, as well as eye movement and other physical response measurements to track customer responses to various stimuli (Kirk, 2024). Abuín Vences, Díaz-Campo, and García Rosales, 2020). These methods enable the capture and analysis of emotional responses, attention levels, and the degree of customer engagement during interactions with marketing stimuli. For

[*] Corresponding author: richard.fedorko@unipo.sk

example, eye tracking and so-called "heat maps" can reveal which parts of a website or advertisement customers focus on most (Kirk, 2024), thereby indicating which visual elements elicit the strongest emotional response.

In e-commerce, neuromarketing can help optimise website design and improve the user experience (Powell, 2024). For example, the use of colours to evoke emotions can influence purchasing behaviour. Red is associated with urgency, blue with trust, and black with high quality (Jules, 2019). Emphasising limited product availability can also create a sense of scarcity, which encourages customers to make a purchase more quickly (Jules, 2019).

Neuromarketing helps reveal hidden emotional stimuli (Darázs, 2024) that influence customers' purchasing decisions. The theoretical frameworks of neuroscience in marketing thus confirm that consumers are not purely rational "homo economicus" (Chen, 2021), but rather, as Portuguese-American neuroscientist António Damásio aptly noted, *"we are not thinking machines that feel, but feeling machines that think"* (Graves, 2015). Emotions are therefore not secondary to decision-making, but are its essence.

Neuromarketing research has also yielded a wealth of specific insights into customer behaviour. For example, the well-known Coca-Cola and Pepsi taste test experiment demonstrated that when test subjects were unaware of which drink they were consuming, their brain activity was associated with the desire for reward. However, when they recognised the brand, a different area of the brain associated with thought processes was activated. This suggests that brands and previous experiences can evoke emotions that can directly influence product perception (Jha, 2004). In the context of e-commerce, this may mean that a strong brand that evokes positive emotions (a feeling of trust, quality) may have a competitive advantage because customers subconsciously prefer products from well-known brands, even if the rational parameters (price, specifications) are similar to those of other products.

Theoretical foundations emphasise that emotional factors are a key determinant of purchasing decisions. Neuromarketing provides a means to measure and analyse these factors using scientific methods, thereby contributing to a deeper understanding of customer behaviour in the digital environment. For e-commerce, where the battle for customer attention and trust is intense, neuromarketing offers valuable insights for creating more effective marketing strategies that are grounded in the customer's emotional experience.

2. Methods

The methodological procedure aimed to analyse the emotional factors influencing consumer purchasing behaviour in the e-commerce environment through a secondary analysis of available academic literature.

The basic selection consisted of eight scientific studies published between 2021 and 2024. The selection was made based on predefined criteria, with an emphasis on:

- thematic relevance (studies focusing on the connection between emotions, purchasing behaviour, and e-commerce),
- methodological diversity (studies applying different research approaches and techniques),
- topicality of the published findings.

The studies were searched for in the Web of Science (WoS) academic database, with the keywords used in the search including the following combinations: ("consumer behavior" OR "online shopping" OR "e-commerce" OR metaverse) AND (emotions OR "purchase decision" OR "impulse buying" OR "perceived value" OR neuromarketing OR "eye-tracking").

The following filter criteria were applied to the search:

- Years of publication: 2021–2024 – to ensure the relevance of the findings,
- Open Access: Yes – to ensure access to full texts,
- Document type: Article – only original scientific articles were included,
- Language: English,
- Web of Science categories: Business, Psychology Multidisciplinary, Multidisciplinary Sciences, Management, Neurosciences.

Based on the above criteria, 352 articles were identified. After evaluating the titles and abstracts, a final selection of 8 studies was made that best met the requirements of the research project. The analysis was conducted in two phases:

- Descriptive phase – a summary table (Table 1) was created, containing basic data on individual studies (title, authors, year, journal title).
- Analytical phase – each of the studies was examined in detail in terms of the research objective, methodology used, and main findings (Table 2). This procedure made it possible to identify common features and differences in approaches to examining emotional influences in the digital shopping environment.

3. Results

Table 2 provides a more detailed analysis of the individual research articles listed in Table 1. It lists the authors and year of publication, the main objective of the article, the research methods used, and the key results or conclusions of the study. This overview provides an understanding of the main contributions of each article.

Table 2. Analysis of the objectives, methods, and results of selected research articles

Author (year)	Objective of the study	Method used	Results and conclusions
Cuong (2024)	To create an analytical framework that includes factors such as sales promotion, hedonistic motivation to shop, and personalisation, to examine their impact on positive customer emotions in an e-commerce environment.	The theoretical basis for the research was cognitive emotion theory, which explores the link between emotions and action tendencies. Data were collected via an online questionnaire.	The results showed that customers' positive emotions were significantly influenced by factors such as sales promotion, hedonistic motivation, and personalisation, with promotion having the greatest impact. At the same time, it was demonstrated that positive emotions have a strong influence on customers' purchase intentions, which in turn significantly impacts their behaviour.
Juanim et al. (2024)	To examine the mediating role of hedonic motivations in the relationship between online advertising stimuli and the impulsive purchasing behaviour of online shoppers.	Quantitative survey using a questionnaire on a sample of 330 respondents. Conditional process analysis was used to analyse the data.	The results showed that online advertising can influence impulsive purchases by stimulating emotional and hedonic motivations. A moderating effect of gender and age was also observed, highlighting the importance of considering demographic factors when developing effective digital marketing strategies.
Pšurný et al. (2024)	The research aimed to investigate how various factors influencing online purchasing decisions affect information processing in the consumer's brain.	EEG combined with eye tracking. Using evoked potential analysis (specifically the P200 and LPP components), differences in the processing of utilitarian and hedonic products were monitored, which were presented alongside visual cues such as reviews, discounts, and quantity discounts.	The findings showed that factors such as reviews and discounts are processed faster by the brain than the products themselves. These responses often occurred even without direct visual focus, suggesting the use of peripheral vision.
Riswanto et al. (2024)	To explore consumer patterns in advertising by integrating big data analysis, eye-tracking technology, and questionnaires to analyse customer satisfaction, visual engagement, and purchase intent.	The study employed big data analysis to identify sentiment clusters from online reviews (product, model, promotion, and effect). Then, it used eye-tracking analysis to measure visual attention when participants viewed advertisements, as well as a questionnaire to determine purchase intent and preferences among the same participants.	The results showed that sentiment clusters related to products, promotions, and effects had a positive influence on customer satisfaction. Eye-tracking data revealed that ads featuring products and models received the most visual attention, while questionnaire results indicated that promotional content had a significant influence on purchase intent. The study emphasised the importance of integrating consumer sentiment analysis with visual engagement metrics in developing effective marketing campaigns.

Fici et al. (2023)	Compare the emotional and cognitive experience of shopping in conventional e-commerce vs. on a metaverse platform.	Researchers used neuroscientific methods (EEG, galvanic skin response, and volume pulse) to capture participants' responses while shopping. Each participant purchased the same product once in the metaverse (Second Life) and once through a conventional e-commerce site. They completed questionnaires after each shopping task.	The findings showed that shopping in the metaverse elicits higher cognitive activity than traditional online shopping, but also places greater demands on memory and mental processing. The metaverse failed to elicit a significantly positive emotional response, which was reflected in a poorer overall shopping experience.
Sun et al. (2023)	To explore the impact of time pressure in live-streaming e-commerce on impulsive shopping and emotions.	Stimulus-Organism-Response (S-O-R) theory and Schachter-Singer theory (SST).	Findings indicate that time pressure is associated with impulsive buying, with more attention being paid to emotional aspects than cognitive ones. Additionally, perceived value mediates the relationship between time pressure and emotional (as opposed to cognitive) impulsive buying. This relationship is strengthened by positive emotions and weakened by negative emotions.
Chen et al. (2022)	The study focused on examining the impact of online product reviews on consumer purchasing decisions.	Eye-tracking experiment: tracking eye movements while reading positive vs. negative user reviews.	Negative comments attracted more attention than positive ones, especially among women. A significant correlation was found between the way reviews were viewed and the intention to make a purchase. At the same time, it was found that consumers were unable to distinguish between fake and genuine comments reliably.
Yarosh et al. (2021)	Identify emotions that predict product selection when ordering food online.	Neuromarketing experiments (eye tracking, facial analysis, polygraph) and statistical methods such as the Kolmogorov–Smirnov test, Mann–Whitney U nonparametric tests, and Kruskal–Wallis H test	The results of the experiment showed that neither the placement of the product on the virtual shelf nor its visibility influenced the consumer's decision. The key factor in purchasing is the established stereotypical attitude towards the product. Statistically significant differences were found between men and women in their online product selection, specifically in emotions such as surprise, pleasure, disgust, and anger. No such differences were observed in sadness and fear. If a product evokes a positive mood, customers prefer it.

Source: Own processing (2025)

Selected studies from 2021 to 2024 confirm that emotions have a significant impact on consumer behaviour in the e-commerce environment. Several studies agree that emotions are not just a side effect of

shopping, but a key determinant that influences both the purchase intention itself and the decision on product selection.

Cuong (2024) identified three main factors that influence positive emotions in e-commerce: sales promotion, hedonistic motivation, and personalisation. Promotion had the most decisive influence, suggesting that consumers are sensitive to marketing stimuli. Pšurný et al. (2024) used EEG and eye tracking to find that visual stimuli such as reviews and discounts are processed by the brain faster than the product itself, even without direct visual focus. This finding supports the thesis that decision-making in an online environment can be influenced more intuitively and emotionally than analytically. From a practical point of view, this means that e-shops should thoroughly optimise visual elements on the home screen.

Using the S-O-R model, they demonstrate that emotions such as enthusiasm, trust, and a sense of urgency arise in response to a charismatic presenter and their interactions with the audience. These emotions play a mediating role between the stimulus and the purchase decision. In this context, impulse purchases are not an anomaly but a typical manifestation of consumer behaviour. Similarly, Sun et al. (2023) highlight the time pressure exerted on customers, which intensifies impulsive buying behaviour, particularly in the presence of positive emotions. This effect is weakened when negative emotions prevail.

Micheletto et al. (2023) compared the shopping experience in traditional e-commerce and in the metaverse. They found that the metaverse increases cognitive load but does not achieve a comparable level of positive emotional response. This discrepancy raises a discussion about whether innovative technologies inherently enhance the shopping experience. Yarosh et al. (2021) draw attention to the specifics of individual emotional experiences. Age, gender, and education influence emotional responses and their intensity. These findings underscore the need for more personalised marketing communications. For example, women statistically pay more attention to negative reviews (Chen et al., 2022), which can influence their decision-making more than price or product brand.

A key finding is that most emotions are not consciously experienced. Methods such as EEG, eye-tracking, and FACS reveal that consumers respond to stimuli even before they are consciously aware of them.

4. Discussion

The results of the secondary analysis confirm that emotions play a crucial role in the e-commerce environment—not only in shaping purchase intent, but also in the consumer's decision-making process itself. This fact highlights the importance of systematically considering emotional factors in marketing strategies, particularly in the design of visual and interactive stimuli within the digital environment.

Neuromarketing techniques, such as eye tracking, EEG, and brain imaging, play a crucial role in identifying website elements that capture attention and facilitate information processing. Their use contributes to more effective searching, evaluation, and selection of products in the online environment (Cenizo, 2025). In line with these findings, optimising visual design, reducing decision options, and personalising content reduce the cognitive load on consumers and streamline the entire purchasing process (Saldaña-Bocanegra et al., 2024).

The findings of the analysed studies also suggest that emotional responses to marketing stimuli often arise before they are consciously and rationally processed. This finding challenges the traditional concept of "homo economicus" and supports the use of complementary neuromarketing tools that allow researchers and marketers to capture nonverbal, subconscious customer responses. EEG and other neuroimaging tools, for example, enable the distinction between positive and negative emotional responses, which can serve as the basis for more accurate tailoring of offers to individual preferences (Ouzir et al., 2024).

Neuromarketing also provides tools for identifying visual, audio, or text stimuli that evoke positive emotions. Such stimuli contribute to higher brand recall, satisfaction with the experience, and customer loyalty (Song et al., 2025; Roy, 2025). Their appropriate application can increase emotional engagement, creating a stronger connection between the consumer and the brand.

However, the degree to which these findings can be generalised remains questionable. Given the methodological diversity of the studies analysed and the variability of the research samples, it is not possible to unequivocally declare their validity across different cultural, age, and technological environments. Moreover, emotional responses are highly individual—their intensity, direction, and consequences vary depending on personality traits, social context, and previous experiences. These differences point to a growing need for personalisation in e-commerce, particularly through the use of advanced real-time analytics (Praveen et al., 2025; Zeng & Marques, 2023).

Creating sensory-rich experiences—particularly through a combination of visual, audio, and interactive elements—can significantly strengthen emotional bonds and increase post-purchase satisfaction (Roy, 2025). However, it is important that these elements are not an end in themselves, but are integrated into a comprehensive strategy focused on consumer well-being and long-term engagement.

Encouraging impulsive buying behaviour is another area where emotional conditioning is applied. Banjongprasert (2024) highlights the crucial role of e-commerce platforms and social media in promoting impulsive purchases, which is closely tied to users' emotional motivations and attitudes. The results of this study suggest that positive emotions and trust in the online environment, especially when using live streaming, increase the likelihood of impulsive decisions.

This assumption is also supported by the findings of Deng et al. (2024), who state that short videos and live broadcasts in social selling influence purchasing behaviour through both emotional and rational processes. Real-time interaction and visual stimuli contribute significantly to impulsive purchases, particularly by activating emotional engagement.

At the same time, it should be emphasised that not all technological innovations in e-commerce automatically lead to positive experiences. The shopping environment in the metaverse, despite its innovativeness, can increase the cognitive demands on the user without guaranteeing adequately strong positive emotions. Singh et al. (2025) point to the complex relationship between value dimensions, customer engagement, and subjective perceptions of satisfaction. Their findings correspond with the results of this study, which suggest that technological complexity does not guarantee emotional intensity.

It follows that neuromarketing approaches represent a promising tool for a deeper understanding of consumer behaviour. Thanks to their ability to reveal implicit, often undeclared customer responses, they offer brands the opportunity to target their communication strategies more accurately. Emotional factors are thus not only the subject of research but also a practical tool for increasing the effectiveness of marketing communication.

Beyari et al. (2024) confirm that the integration of neuromarketing methods—particularly EEG, eye tracking, and AI tools—enables more accurate mapping of customers' emotional responses and their connection to purchasing behaviour. These findings underscore the importance of applying neuroscience tools in practice to develop more targeted, emotionally engaging, and sustainable marketing strategies.

Conclusion

An analysis of selected studies from 2021 to 2024 confirms that emotions are a key determinant of purchasing behaviour in e-commerce. Emotional responses often precede rational thinking and have the ability to influence decisions in real time. Marketing stimuli, such as discounts, reviews, time pressure, or personal contact in a live stream, can trigger positive or negative emotions that shape purchasing intent and behaviour. Neuroscience methods such as EEG, eye-tracking, and FACS provide a helpful tool for analysing these processes, opening up new possibilities for effective digital marketing communication.

The findings also confirm that sensory and interactive elements in the online environment—such as colours, sounds, and moving visuals—play a significant role in shaping emotional engagement and customer loyalty. Personalised and emotionally charged digital strategies based on real-time data appear to be an effective way to build longer-term relationships with customers.

An important implication for marketing practice is that technological innovation (e.g., the metaverse) may not automatically lead to higher customer satisfaction if it fails to consider the emotional needs of users. Neuromarketing, therefore, offers not only a diagnostic framework but also application potential in designing sustainable and emotionally effective communication strategies.

The limitations of this study are the limited number of works analysed and the fact that it was a secondary analysis. Future research could expand knowledge, for example, on the influence of cultural environment, age, or digital literacy on emotional decision-making, as well as verify selected findings.

It is also recommended to conduct experimental studies in real e-commerce environments that would combine neuroscientific methods with the monitoring of behavioural indicators (e.g., conversion rate, customer return rate). Such an approach could contribute to a better understanding of the dynamics between emotional stimulation and specific consumer decision-making behaviours.

The Marketing Power of Customer Reviews in Hospitality Industry

***Lujza* Gunišová**[1,*] **and *Peter* Štarchoň**[1]

[1] Comenius University Bratislava, Department of Marketing and Commerce, Faculty of Management, Odbojárov 10, 820 05 Bratislava, Slovakia

Abstract

Research background: Customer feedback has become a key factor in shaping consumer behavior and influencing service quality, especially in the hospitality industry. Online reviews are now perceived as a modern form of word-of-mouth communication that significantly impacts the reputation and performance of businesses. Simultaneously, mystery shopping remains a structured method for evaluating service standards and employee performance. Despite their relevance, limited research exists on how hospitality decision-makers perceive and use these tools in practice—particularly in smaller urban markets like Bratislava.
Purpose of the article: This article explores how hospitality decision-makers perceive and utilize online reviews and mystery shopping. It aims to identify current attitudes and practices related to customer feedback, and assess the potential of these tools for improving service quality, marketing strategies, and overall performance. The study also examines future business opportunities arising from the strategic use of feedback mechanisms.
Methods: The study employs qualitative methods, specifically semi-structured in-person interviews with five Bratislava-based hospitality decision-makers. Participants included owners and managers with direct influence on service and marketing. Interviews were thematically structured around four areas: perceptions of online reviews, their application in business, the role of mystery shopping, and potential business opportunities. The data were analyzed using qualitative content analysis to identify key patterns and insights.
Findings & Value added: The findings indicate that although respondents do not consistently rely on reviews in their personal decisions, they recognize their influence on customer decisions and business reputation. Most respondents actively manage reviews, particularly negative ones, and view them as valuable feedback. Mystery shopping is used informally but appreciated for its targeted evaluation. The findings reveal a gap between current practices and the strategic potential of feedback tools. The study suggests opportunities for further development, particularly in services supporting review management and customized mystery shopping solutions for the hospitality sector.

Keywords: Online reviews, Mystery shopping, Hospitality industry, Customer feedback, Review management

JEL classification: M31, L83.

1. Introduction

With customer feedback influencing both perception and performance, this research explores how decision-makers in hospitality understand and respond to reviews, offering insights into their foundational attitudes toward service quality. The aim of this article is to explore the initial attitudes and perspectives of decision-makers in relation to the provision of services within the hospitality sector. It focuses on understanding how these stakeholders perceive key aspects of service quality, customer feedback, and operational improvement.

Reviews play a key role in shaping consumer choices regarding products, services, and retailers (Thakur, 2018). Online user ratings are often associated with some form of social influence, where one consumer bases his or her purchasing behavior on the judgment of another (Gavilan, Avello & Martinez-Navarro, 2018). Online reviews have seen a significant boom in recent times as the source of crucial information for consumers, influencing approximately 20% to 50% concerning online purchases (Mathwick Mosteller, 2016).

* Corresponding author: gunisova15@uniba.sk

Reviewers serve as valuable sources of information for prospective buyers. For instance, many consumers return to specific websites to browse and read reviews while considering the decision to choose those products or services (Mathwick & Mosteller, 2016).

Online ratings are considered to be among the most trusted sources for e-commerce decisions, with consumers typically viewing them as reliable and credible. Consumers believe such ratings to be the second most reliable source of brand information, holding the second place right after recommendations from friends and family (Gavilan, Avello & Martinez-Navarro, 2018).

Online reviews generated by consumers are often viewed as more trustworthy than information provided by sellers, due to the perceived reliability of the source (Bickart & Schindler, 2001). According to research by Bickart and Schindler (2001), consumers who interact with peer-generated content display higher rates of engagement and interest levels compared to those exposed to marketer-generated information.

Online reviews are defined as follows: assessments provided by individuals with direct and hands-on experience, emphasizing the importance of sharing personal experience with other consumers. As a result, this is most likely to lead to enhanced sales and shifts in consumer attitudes (Mudambi & Schuff, 2010; Sparks & Browning, 2011).

Online consumer reviews are seen and perceived as a form of word-of-mouth communication (Godes & Mayzlin, 2004). Similar to word-of-mouth communication, studies have found that online reviews are thought to be more credible, empathetic, and relevant to customers in comparison to the information which is provided by the marketing teams (Bickart & Schindler, 2001; Godes & Mayzlin, 2004).

Unlike traditional word-of-mouth communication, online reviews are most likely to reach a global audience while technology enables sellers to easily share reviews on their websites (Chen & Xie, 2008).

The measurement of customer satisfaction is a widely known and proven practice in the hospitality sector, commonly achieved through the use of customer feedback mechanisms such as: comment cards, online surveys, and third-party evaluations by consultants or mystery shoppers (Chen & Barrows, 2015).

As the Internet becomes an integral part of our daily communication, online reviews are getting more and more relevant for evaluation of service quality for certain products or services or businesses as a whole (Selem et al., 2023).

Customers often rely on online reviews to guide their decisions when choosing a restaurant or hotel (Lee & Kim, 2020). Building enough trust in user reviews on hotel sites now surpasses travel agent recommendations. Hospitality marketers should recognize the influence of consumer power as well as their ability to change public opinion, yet many remain uncertain about how to manage user reviews and social media (Ong, 2012).

Meira et al. (2022) found that human resource practices and employee motivation significantly influence online hotel reviews. While motivation driven by external factors also known as extrinsic showed a very positive impact on overall ratings, on the other hand motivation driven by internal factors, also known as intrinsic, showed a negative effect. These findings suggest that hoteliers can enhance review rating, a key performance indicator, by leveraging human resource strategies to further improve employee motivation. However, the question still remains as to how hotels can identify if negative reviews originate from underlying issues in their human resource practice or if there are other factors in place.

Reviews strongly influence customer behavior and are widely used by hospitality businesses to guide improvements. However, there is still limited understanding of how businesses interpret this feedback and how it aligns with customer expectations, highlighting the need for further research into both perspectives.

Mystery shopping vs. Online reviews

Mystery shopping is recognized as a valid method for performance evaluation across various industries (Allison & Severt, 2011). Employee training has emerged as a critical factor influencing business outcomes (Ostin, 2023), mystery shopping serves as the valid method for objectively evaluating employee attachment to organizational standards. On top of that, it also creates a feedback loop that supports the development of targeted training programs and ensures consistent service quality (Chen & Barrows, 2015).

The main principle of mystery shopping is as follows: assigning individuals to evaluate the real-time quality of services, documenting their assessments of service delivery and determining whether employees meet or exceed the company's established standards (Chen & Barrows, 2015).

Research (Torres et al., 2013) shows and mainly highlights a strong correlation between feedback coming from consumers, particularly online reviews, and increased customer satisfaction. While some hospitality managers prioritize digital platforms e.g. TripAdvisor, others continue to still put value into

traditional feedback channels, including direct customer correspondence. The study identified two primary aspects of feedback influence: one emphasizing online reviews alongside meeting planner input, and another integrating online reviews with consumer ratings. These findings underscore the need for a holistic feedback management strategy that incorporates diverse sources to effectively enhance service quality and overall customer satisfaction.

The study by Boukhaoua, Habbache, and Zerouati (2025) shows that while rated hotels apply relationship marketing, improvements are needed in service culture and communication, with complaints management being the weakest area. Strengthening these elements can enhance guest satisfaction, loyalty, and hotel performance.

Both mystery shopping and online reviews contribute to understanding service performance - one through controlled assessment, the other through customer perception. Future research should explore how best to align these tools for optimal impact.

2. Methods

The research focused on understanding how decision-makers in the hospitality sector perceive online customer reviews, how they leverage them in marketing, and what business opportunities they associate with this form of customer feedback. The aim was to identify not only current attitudes and practices but also potential for more strategic use of reviews in improving service and customer experience.

Semi-structured individual interviews

The study was conducted through semi-structured face-to-face interviews with decision-makers from the hospitality industry in Bratislava, Slovakia. The participants included owners, managers, and operators of hospitality establishments, all of whom hold the authority to make decisions related to service quality, marketing, and customer experience in their businesses. The selection of participants was based on recommendations, with the intent to cover a diverse sample of businesses within the industry.

A total of five interviews were conducted in May 2025. All interviews were conducted in person, allowing for deeper engagement and richer data collection. The qualitative approach was chosen to explore in depth the perceptions and practices related to online reviews, rather than to quantify responses.

Table 1. Respondents

No.	Role	Facility type	Length of business operation	Target customers
1.	owner	a network of food court establishments	june 2017	urban professionals, trendy food lovers, families, and value-conscious customers who seek authentic, healthy, and visually appealing food with a story – served quickly, with quality, and in a modern, engaging way
2.	owner	multiple cafes	first cafe in 2020	people who value comfort, well-being, and a welcoming atmosphere - a community-oriented audience from the local area who appreciate quality over low-cost options
3.	owner	restaurant	april 2022	all people and visitors in the surrounding area
4.	owner	multiple restaurants	july 2017	local residents, families with children, and professionals such as senior managers, politicians, actors, and athletes who value a high-quality dining experience - whether for a relaxed family meal or a refined business lunch
5.	owner and manager	restaurant	february 2025	local customers who seek high-quality experiences without traveling to Bratislava, aiming for premium offerings with the potential to attract a broader regional audience in the future

Source: custom processing

Each interview was structured around four core thematic blocks. The first block explored how respondents perceive the significance of online reviews. The second focused on how reviews are used as part of the business's marketing strategy. The third examined the identification of potential business opportunities stemming from online feedback. The final block addressed the use of mystery shopping as a tool to improve services and its connection to online customer feedback.

The data were analyzed using a simplified qualitative content analysis. Although the coding and interpretation were conducted by a single researcher, care was taken to ensure consistency in categorizing key themes across interviews. The insights presented below reflect recurring patterns and unique perspectives collected during the interview process.

3. Results

The findings reveal that while not all respondents personally consider online reviews as a critical factor in their own consumption decisions, they consistently recognize their importance in shaping the decisions of potential customers regarding their establishments. Respondents perceive online reviews as trustworthy primarily when written by verified users who have posted a significant number of constructive reviews. Conversely, reviews from fake profiles or those several years old are generally viewed as unreliable.

Respondent 2 highlighted the importance of reviews for visibility in digital search engines: "Reviews are necessary not only for the owner but also for Google, where they determine how Google recommends you." Respondent 3 noted the practical value of reviews in business management: "Reviews-ours and those of the competition-are useful because they show what bothers people, what they notice, and help us improve our service." Respondent 5 does not consider online reviews a replacement for traditional advertising, but views them as a highly important tool for verifying the quality of a specific restaurant. They attach significant value to them, considering reviews that include photos to be the most relevant.

Respondents reported monitoring reviews on a regular basis. In some cases, the establishment's online profile was created by customers, prompting the business owner to start engaging with the platform. Most respondents actively monitor reviews and assign responsibility either to the owner or a designated staff member. Majority (3 out of 5) of respondents stated that responses to reviews are typically provided within 48 hours, with particular attention given to negative feedback. While positive reviews are appreciated, they are rarely addressed in detail unless they contain descriptive content. Reviews without explanation, whether positive or negative, were largely considered meaningless by respondents.

The style and tone of responses vary: some use a standardized corporate communication style, others respond based on the tone of the review, and a few contact customers directly to resolve specific issues. Respondent 1 reported maintaining a 100% response rate and having a compensation framework based on the nature of the feedback.

Efforts to gather reviews differ by establishment. Respondent 2 stated they use QR codes, respondent 1. noted they use contactless chips placed on tables, while others rely on verbal prompts from staff after a positive customer experience. Respondent 1 also mentioned a staff training program specifically focused on how to ask for reviews. Despite these efforts, some respondents noted that Slovak customers are often reluctant to raise issues directly with staff during their visit, preferring instead to express dissatisfaction later through an online review.

All respondents acknowledged the value of customer feedback in improving staff performance, product quality, and service standards. In several cases, staff were confronted with review content, and in extreme situations, termination of employment was considered if issues were not resolved.

While respondents appreciate public reviews, they also highly value direct, in-person feedback from regular customers. Traditional advertising still plays a role; respondent 3 stated that large physical banners are often more visible to the public than online reviews, suggesting that not all customer segments engage with digital reviews equally.

Review management practices are typically handled in-house, although respondent 2 mentioned occasional cooperation with an agency or through public relations articles. The current level of review utilization was described as insufficient, and some respondents acknowledged room for improvement.

Although offering rewards for positive reviews is common practice abroad, most respondents were hesitant to adopt such strategies, citing concerns about authenticity. Some respondents expressed interest in tools that could support review management, while others felt such tools were unnecessary given their current review volume.

Regarding mystery shopping, respondents who use it (respondent 2 and 3) tend to rely on informal methods, such as asking friends or acquaintances to visit anonymously and report their experiences. Respondent 3 explicitly stated a reluctance to pay for mystery shopping services, noting that "Google reviews are free." Nevertheless, mystery shopping was seen as useful, especially for evaluating service quality, employee behavior, upselling, first impressions, visual aspects of the venue, cleanliness, and employee presentation.

4. Discussion

The results demonstrate a widespread recognition among hospitality decision-makers of the influence online reviews exert on customer behavior. While personal reliance on reviews varies, all respondents acknowledged their significance in the context of business visibility and customer acquisition.

Credibility plays a critical role in how reviews are perceived and utilized. Reviews from active, authentic profiles that provide constructive criticism are regarded as highly valuable, while anonymous or outdated reviews are dismissed.

Respondents' practices indicate a proactive approach to review management, particularly in addressing negative feedback. The form and style of responses are tailored, and mechanisms for compensation or resolution are present in more organized businesses. Importantly, most participants emphasized that reviews without specific content offer little managerial value, reinforcing the importance of actionable feedback.

Despite using informal tools and internal resources, several respondents expressed a need for improved systems to manage and respond to reviews effectively. While some employ digital methods to collect reviews, such as QR codes and staff training, their effectiveness appears mixed.

Mystery shopping was viewed as a complementary tool to online reviews. Although often conducted informally, it was valued for its ability to provide focused, specific insights into service performance. Unlike online reviews, which are public and user-generated, mystery shopping is private and controlled, allowing businesses to target key service parameters.

Interestingly, the findings suggest that direct, face-to-face feedback is still regarded as highly valuable. Respondents also indicated that traditional advertising plays an important role, especially in reaching customer segments less engaged with online platforms.

Conclusion

This study provides insight into how hospitality decision-makers in Bratislava perceive and utilize online reviews and mystery shopping as tools for improving service and reputation. The findings confirm that while not all respondents rely on reviews in their personal decisions, they fully acknowledge their influence on customer perceptions and business visibility.

Respondents take an active role in monitoring and responding to reviews, particularly negative ones, which they see as opportunities for improvement. Mystery shopping, although less formalized, is employed selectively as a means of obtaining targeted feedback. Both forms of feedback are considered valuable, but each serves distinct purposes.

The study also highlights areas for further development, particularly in the strategic use of online reviews. While there is interest in technological support for review management, uptake remains limited. Similarly, while review-driven marketing practices are recognized abroad, Slovak respondents tend to avoid incentivizing positive reviews.

This research may serve as a foundation for further studies. It is essential to explore online reviews from the customer's perspective and assess their actual impact on purchasing decisions. In addition, in-depth research on the use of mystery shopping is warranted, as it appears to be a relevant yet underexamined tool. Specifically, future research should aim to identify which factors and evaluation parameters are most important for businesses and compare them with the criteria valued by customers during their decision-making processes.

Finally, the findings suggest several business opportunities. These include the development of services that collect, analyze, and deliver structured review insights to hospitality businesses, as well as the creation of a mystery shopping agency tailored specifically to the needs of the hospitality sector. Such initiatives could help bridge the gap between customer expectations and service delivery, enhancing competitiveness and overall guest satisfaction.

The Impact of Unexpected Changes on the Determinants of Family Business in the Slovak Republic

***Martin* Halász**[1,*]**, *Andrea* Janáková Sujová**[1]**, and *Mariana* Sedliačiková**[1]

[1] Technical University in Zvolen, Department of Economics, Business and Management, Faculty of Wood Sciences and Technology, T. G. Masaryka 24, 960 01 Zvolen, Slovakia

Abstract

Research background: Family businesses form an essential part of the Slovak economy, characterized by generational continuity and close ties between owners and employees. However, their long-term sustainability is often threatened by unexpected external shocks. The COVID-19 pandemic exposed several vulnerabilities in family businesses, particularly in areas such as finance, marketing, and human resource management, highlighting the importance of preparedness and adaptability.
Purpose of the article: The main aim of this article is to analyze the impact of unexpected changes on the key internal and external determinants of family businesses in the Slovak Republic. The research also seeks to identify which areas were most affected by the pandemic and how these enterprises responded to the challenges it presented.
Methods: The study is based on a quantitative research design using a questionnaire survey conducted with 403 family businesses across Slovakia. The obtained data were analyzed using descriptive statistics and the Analysis of Variance (ANOVA) method. The statistical tools used included Microsoft Excel and Statistica 14.
Findings & Value added: The results show that the most affected internal areas were finance, marketing, and human resources, while external pressures mainly stemmed from disrupted supply chains, shifts in customer behavior, and increased competition. The majority of businesses relied on their own resources rather than state aid. The findings underline the importance of strategic resilience, financial planning, and digital transformation in increasing the robustness of family businesses. The paper provides valuable insights for policymakers and entrepreneurs in designing more effective support mechanisms to prepare businesses for future crises.

1. Introduction

The COVID-19 pandemic, declared by the World Health Organization in March 2020, has caused unprecedented global disruptions that have had serious economic consequences. Globally, there has been a significant decline in GDP, rising unemployment, and disruption of supply chains, which has caused significant problems for the business sector (Brodeur et al., 2021). Family businesses, which make up a substantial part of the economy of many countries, including Slovakia, have been significantly affected (Sedliačiková et al., 2024). Although these businesses are known for their flexibility, resilience, and ability to quickly adapt to changing market conditions, the pandemic has exposed their weaknesses, especially when it comes to financial reserves and generational renewal (Poláková et al., 2023).

Family businesses represent a specific segment of the business sphere that is characterized by a long-term vision, close ties between family members, and generational continuity (Rovelli et al., 2021). They provide up to 60% of jobs in the European Union, underlining their importance at the macroeconomic level (Sharma, 2004). In Slovakia, family businesses are estimated to contribute 30-40% to GDP and employ more than 40% of the workforce (Halasz et al., 2023). Although family businesses have some advantages over large multinational corporations, they faced several challenges during the pandemic that affected their stability and long-term sustainability.

[*] Corresponding author: xhalasz@tuzvo.sk

During the crisis period, it has been shown that although family businesses are able to respond more quickly to changes compared to large firms, their strong links to local markets and limited financial reserves have made them vulnerable to economic shocks (Poláková et al., 2023). The pandemic has led to fundamental changes in consumer behaviour, with the decline in demand for certain products and services causing financial difficulties for many family businesses (Aparicio et al., 2021). Many companies have had to rethink their business models, intensify digitization, switch to online sales, and look for alternative forms of financing (Kocianová et al., 2022). The problems were not limited to economic factors; A large number of businesses have also experienced generational change, as the pandemic has caused health complications or deaths of key leaders in family businesses. Many businesses were not prepared for the sudden loss of leaders, which caused uncertainty in the long-term strategic direction (Sedliačiková et al., 2024).

In addition, external factors such as disrupted supply chains, shortages of skilled labour, and rising raw material costs have complicated the functioning of family businesses and reduced their competitiveness (Halasz et al., 2023). Despite these challenges, however, many family businesses were able to adapt and look for new ways to strengthen their market position. The rise of digitization, automation, and the implementation of innovative solutions has allowed some businesses not only to survive, but also to increase their efficiency and market competitiveness (Sedliačiková et al., 2024). The long-term impacts of the pandemic have shown that the resilience of family businesses and their preparedness for future crisis situations is a key factor in their survival and growth.

Family businesses play an irreplaceable role in the global and local economy. They form the basis of economic stability, promote employment and contribute to regional development. In many countries, they are a pillar of the national economy, and their ability to withstand crises is crucial for the stability of the entire economic system (Sharma, 2004). In Slovakia, family businesses have a long tradition and significantly affect the economic development of the country. They form a substantial part of the SME sector, thus contributing to market diversification and strengthening local economies (Halasz et al., 2023). Their survival and development in times of crisis is essential for the stability of the domestic economy, which is why it is important that they have access to effective support mechanisms such as tax breaks, financial incentives and expert advice (Sedliačiková et al., 2024).

This research aims to analyze the impact of unexpected changes on the determinants of family business in the Slovak Republic, identify the key challenges that family businesses faced during the pandemic, and provide recommendations to improve their resilience to future economic shocks. The results of this analysis will provide valuable insights for policymakers, entrepreneurs and academia.

2. Methods

The chosen methodological procedure of the conducted research was divided into several consecutive parts, which have a logical interconnection with each other. In the first part, in the form of analysis, synthesis, deduction, description, comparison, summarization and analogy, an analysis of secondary sources focused on the COVID-19 pandemic, its impacts on the local and global sphere as well as family business along with its specifics was carried out.

The second part of the research was devoted to the analysis of primary data obtained through conducting a questionnaire survey. The survey was conducted through the Google platform in the period from February 2024 to May 2024. In the conditions of the Slovak Republic, 60% to 80% of businesses are family businesses (Peráček et al., 2020). In our research, we worked with an average value of 70%. It follows from the above that our basic set consisted of 403,556 family businesses (Finstat, 2024) in Slovakia, operating according to the legislatively anchored definition of family business valid from 1 January 2023, which sets criteria for family businesses in the area of ownership, management and involvement of family members in business activities. Our sample consisted of 4,690 family businesses, which were selected using a random selection generator. This method also ensured that each of the family businesses had an equal chance of being selected, with RPs from all regions of the Slovak Republic being selected. In total, we managed to receive 403 completed questionnaires from family businesses.

The questionnaire survey was divided into several parts. In the first part of the questionnaire, we focused on identification questions regarding our research sample. We were interested in the position in the company, the number of employees, the legal form and the age of the company.

In the second part of the questionnaire, the determinants that had a major impact on the family business due to unexpected changes during the COVID-19 pandemic were examined. In this part, we asked respondents about the impact of the pandemic on their business, their satisfaction with the government

measures taken and the fact that they have received help from available sources. We were also interested in the comparison of internal barriers in terms of their challenge before and during the pandemic, as well as the comparison of external barriers in terms of their challenge before and during the pandemic.

The third part of the research focused on the evaluation of the data contained from the questionnaire survey. The data were primarily evaluated using descriptive statistics and the statistical method analysis of variance (ANOVA), using Microsoft Excel and Statistica 14. At the beginning, it was necessary to determine the minimum size of the research sample (n), which is a fundamental condition for generalizing the results (Labudová et al., 2021):

$$n \geq \frac{z^2 \,.\, p \,.(1-p)}{c^2} \tag{1}$$

Where "z" is the critical value of the normalized normal distribution for 95% confidence, "n" is the minimum number of respondents surveyed, "p" is the estimate of the proportion of the population and "c" is the tolerable error level. For the research in question, it is necessary to make a correction in terms of specific RP characteristics, variability within RP and accuracy and reliability of results. The following calculation was performed to carry out this correction (Labudová et al., 2021):

$$n_{correction} \geq \frac{n}{1+\frac{n-1}{pop}} \tag{2}$$

Where variable "n" expresses the sample size without considering the population and "pop" expresses the population size. The results of the comparison of individual barriers before and during the pandemic were verified through a variance analysis, which told us whether there were statistically significant differences in the intensity of perception of individual barriers before and during the pandemic. The analysis of dispersion allowed us to identify which barriers have experienced more significant changes and thus better understand the impacts of the pandemic on the business environment. The test characteristics were as follows (Pacáková et al., 2009):

$$F = \frac{MSA}{MSE} = \frac{\frac{SSA}{k-1}}{\frac{SSE}{n-k}} \tag{3}$$

Where „MSA“ represents the mean of the deviations of squares for factor A, MSE represents the mean of the deviations of squares for chance E, SSA expresses the sum of variability between individual groups, SSE expresses variability within groups, and relations k – 1 together with n – k express individual numbers of degrees of freedom.

3. Results

The return on the questionnaire survey reached 8.59%, i.e. 403 Slovak family businesses. With a population size of 576 508 enterprises with a 5% margin of error and a 95% confidence level, the minimum number of respondents required is 384. From the above, we conclude that the condition of generalization of the results to the entire population has been met.

The results regarding the identification of our research sample are presented in the form of Table 1.

Table 1. Basic identification of research sample

Questions	**Answers**				
Position in the enterprise	Owner	Manager	O or M	Employees	Other
	22.5 %	*17.9 %*	*31 %*	*28.1 %*	*0.5 %*
Enterprise size	Micro (1 – 9 employees)	Small (10 – 49 employees)	Medium (50 – 249 employees)	Large (500 or more employees)	
	49.3 %	*28.1 %*	*15.7 %*	*6.9 %*	
Enterprise age	< 5 years	6 to 15 years	16 to 25 years	26 years >	
	6.5 %	*87.1 %*	*5.6 %*	*0.8 %*	
Enterprise legal form	Self-employed	Ltd.	Joint Stock	Other	
	10.6 %	*39.9 %*	*27.2 %*	*22.3 %*	

Source: own processing (2024)

From Table 1, we can see that the majority of respondents hold the position of owner (86 enterprises), manager (69 enterprises) or combined function (119 enterprises). Micro enterprises dominate by enterprise size (189 enterprises), followed by small enterprises (108 enterprises), with medium and large enterprises accounting for a smaller share. In terms of the age of the enterprise, the largest share is made up of enterprises with a lifespan of 6 to 15 years (334 enterprises), while younger enterprises under 5 years of age and older enterprises over 26 years of age represent only a small share. In terms of legal form, family businesses are most often found as limited liability companies (153 enterprises), with only 41 enterprises being self-employed.

In the next part of the research, we addressed questions about the pandemic impacts on family businesses as well as the determinants that affected family business. The results of the questions about the pandemic's intervention in business and satisfaction with the government measures taken are shown in Figure 1 and 2.

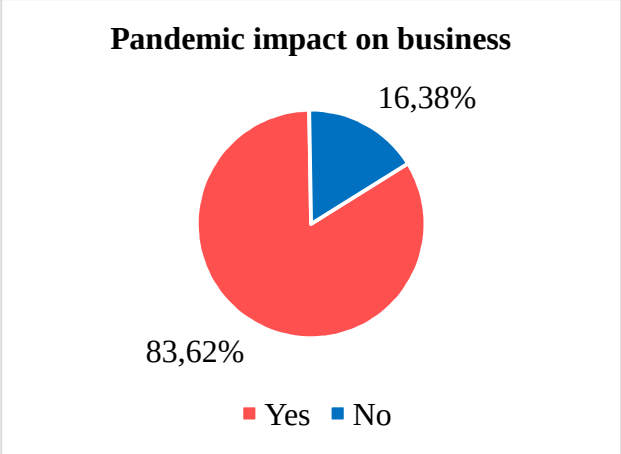

Figure 1. Pandemic impact on business
Source: own processing (2024)

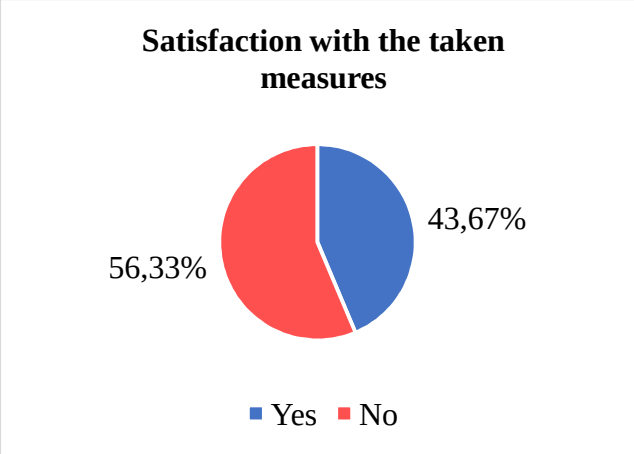

Figure 2. Satisfaction with the taken measures
Source: own processing (2024)

From Figure 1, we see that most family businesses (337 businesses) experienced a negative impact of the pandemic on their business, while only a minority (66 businesses) reported that the pandemic had no impact. This suggests that the crisis period significantly affected the operation of family businesses, probably due to the action of various determinants. Figure 2 shows the level of satisfaction of entrepreneurs with the government measures taken during the pandemic. The results indicate that most respondents (227 companies) were not satisfied with the measures, while 176 companies evaluated the measures positively. This ratio points to a prevalent dissatisfaction with support and regulations, which may be related to administrative burdens, insufficient compensations or inefficiencies of the measures put in place.

In the following graph, we have addressed the issue of drawing aid using various sources. The results are shown in Figure 3.

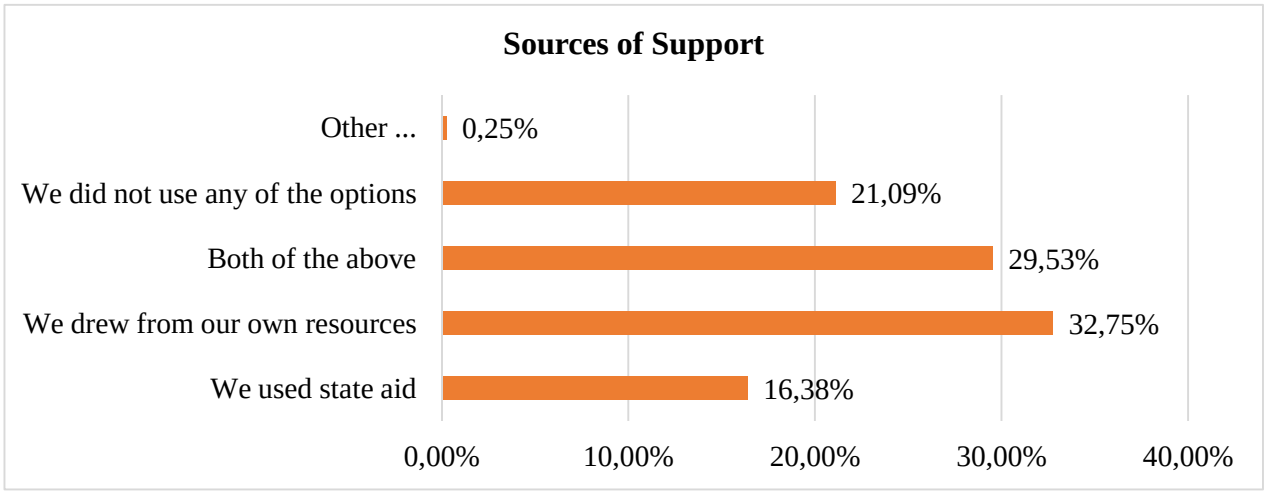

Figure 3. Sources of Support
Source: own processing (2024)

In Figure 3, we can see that most family businesses drew financial resources from their own reserves (132 enterprises), which represents 32.75% of respondents. The second most common strategy was the use of a combination of own resources and state aid, which was chosen by 119 enterprises (29.53%). By contrast, 85 enterprises (21.09%) did not make use of any of the support options and relied on normal operation without additional resources. State aid was drawn independently by 66 enterprises (16.38%). In the "other" option, respondents answered only in a few cases (1 enterprise; 0.25%), and their answer was that they did not use state aid because the company was still operating during the pandemic, and at the same time they refused state aid due to the strict controls that this aid entailed.

The following section of the results deals with the determinants that affected the family business before and during the COVID-19 pandemic. The results are presented separately for internal barriers and separately for external barriers. Figure 4 presents a comparison of the internal barriers of family business in terms of their challenge.

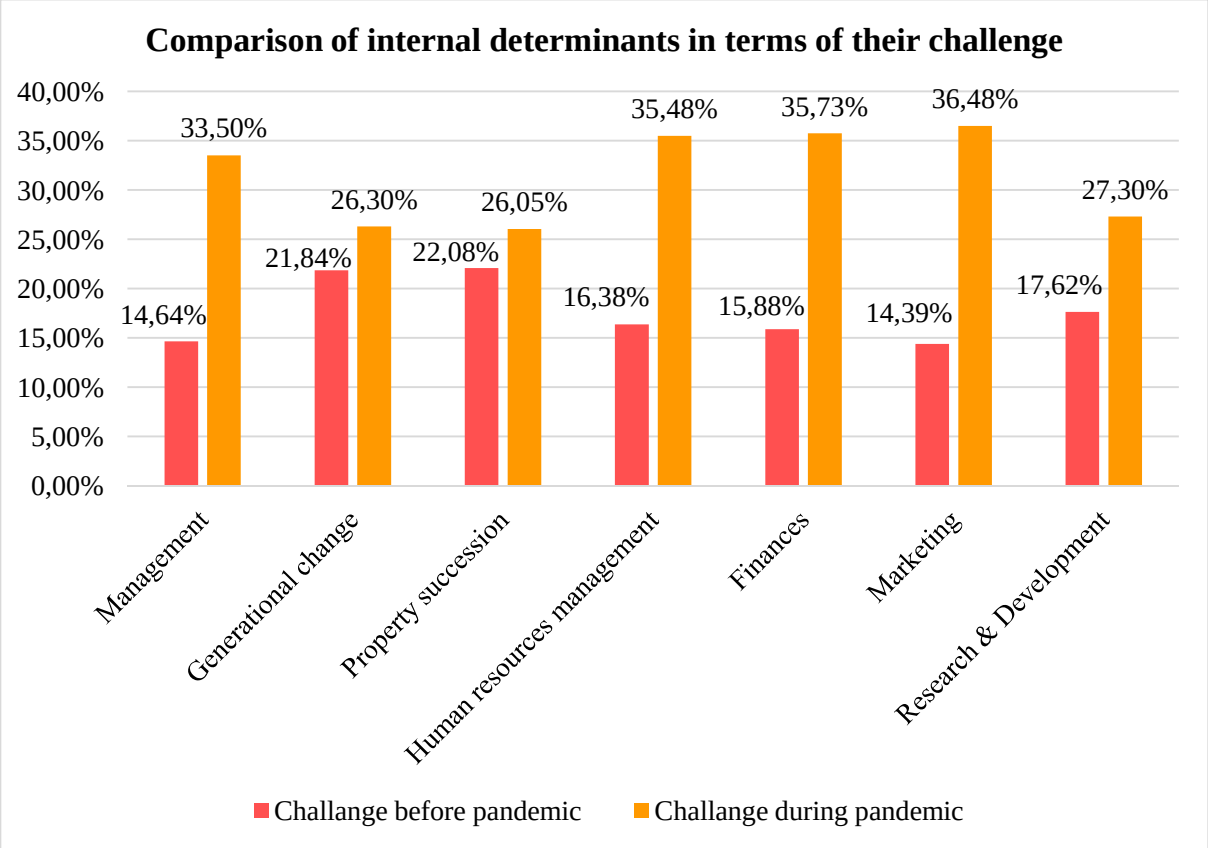

Figure 4. Internal determinants before and during pandemic
Source: own processing (2024)

From Figure 4, we can see that the pandemic has hit the determinants in marketing, finance and human resources the hardest, which have become much more difficult challenges for family businesses than before the pandemic. Marketing was perceived as a problem by 58 businesses before the pandemic, but during the pandemic this number rose to 147, suggesting that businesses had to look for new ways to reach customers and adapt to changing market conditions. Before the pandemic, 64 companies experienced financial challenges, but during the pandemic they rose to 144, pointing to increasing financial constraints, impaired access to liquidity and cash flow problems. The area of human resources has also seen a significant increase – before the pandemic, 66 companies perceived it as an important determinant, but during the pandemic their number rose to 143. This suggests that family businesses have had to deal with staff shortages, changes in working conditions and a shortage of skilled labour. The results thus show that family businesses faced financial difficulties, problems with employees and the need to adapt their marketing strategies to new market conditions during the pandemic. These factors have significantly affected their stability and ability to respond effectively to a crisis situation.

The comparison of individual internal determinants was supplemented by the use of the statistical method of variance analysis, which made it possible to verify statistically significant differences in the intensity of perception of determinants before and during the pandemic, thus providing an objective view of changes in their perception. The results are presented in the form of Figure 5.

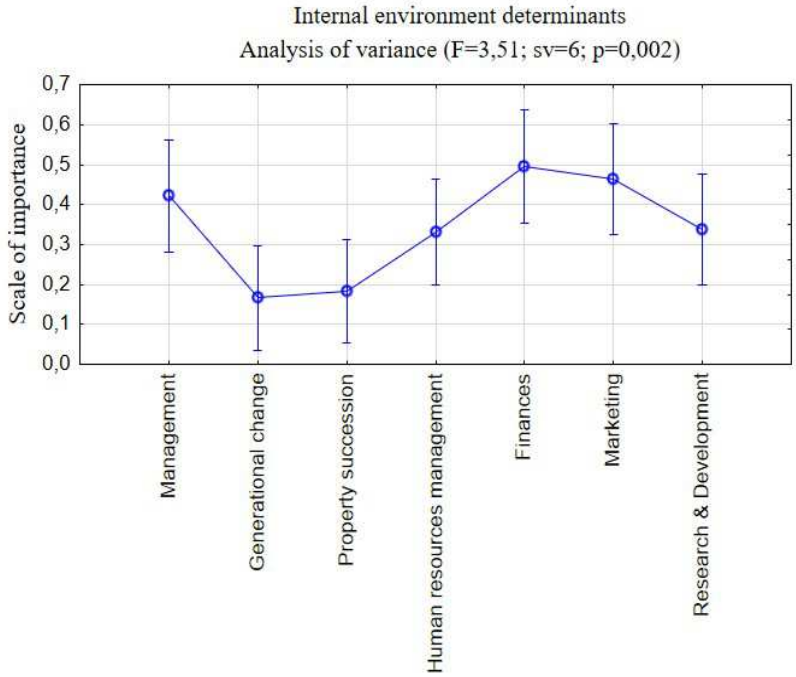

Figure 5. Internal environment determinants
Source: own processing (2024)

From Figure 5, we observe that finance, marketing and management were perceived as the most important internal determinants of family businesses during the pandemic. The analysis of variance confirmed statistically significant differences between the assessment of determinants before and during the pandemic (p = 0.002), suggesting that certain areas of business were hit harder by the crisis period. Other factors, such as generational renewal and R&D, remained present, but to a lesser extent influenced business decisions during the pandemic.

We focused on the external determinants of the microenvironment that directly affected the external environment of family businesses before and during the pandemic. The results are shown in Figure 6.

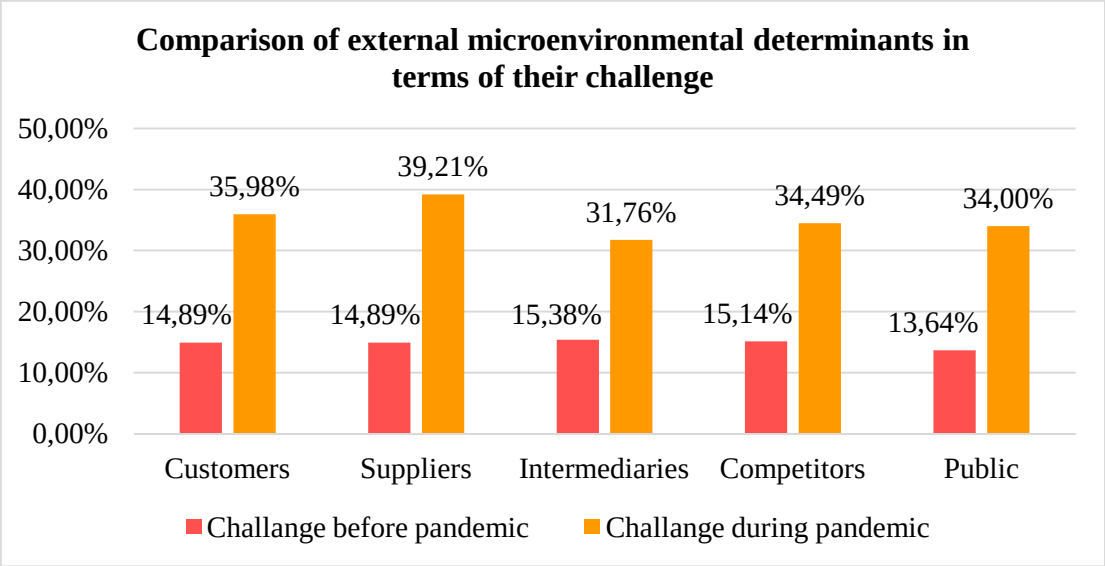

Figure 6. External microenvironmental determinants before and during pandemic
Source: own processing (2024)

From Figure 6, we can observe that during the pandemic, the determinants associated with suppliers, customers and competition deepened most significantly. Supply problems have grown from 60 to 158 businesses, indicating disruption of supply chains. The number of businesses perceiving customers as a barrier has increased from 60 to 145, which may be related to the decline in demand. Competition has become a challenge for 139 businesses compared to 61 before the pandemic, reflecting the intensified struggle for survival in the market. These results show that the pandemic has had a major impact on business relationships and market conditions for family businesses.

The comparison of individual external determinants of the microenvironment was supplemented by the use of the statistical method of variance analysis. The results are presented in the form of Figure 7.

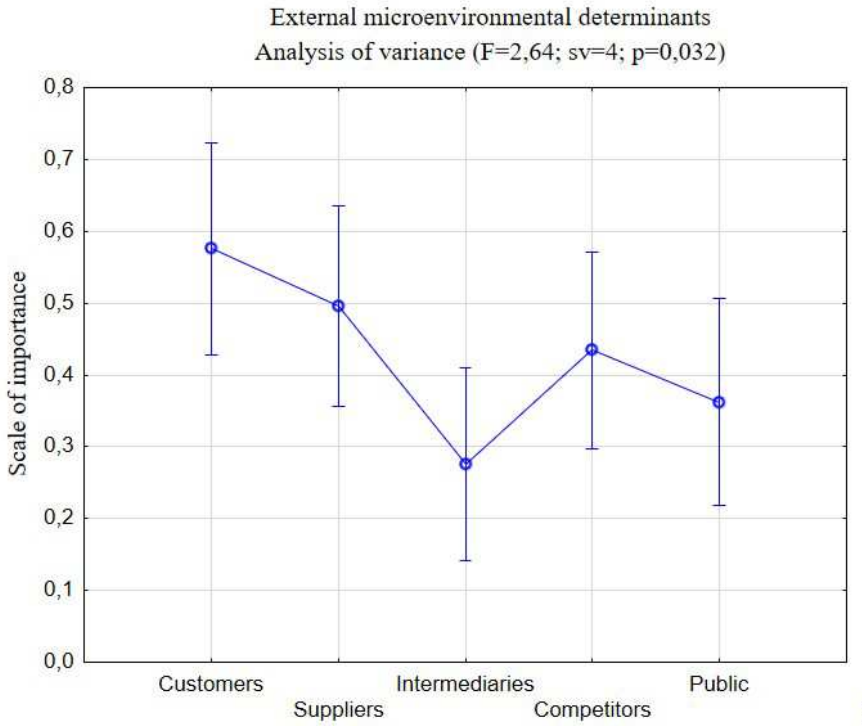

Figure 7. External microenvironmental determinants
Source: own processing (2024)

In Figure 7, we can see that the analysis of variance confirmed statistically significant differences between the external determinants of the microenvironment of family businesses during the pandemic ($p = 0.032$). The most important determinants became the customers and suppliers who achieved the highest values of importance. This suggests that family businesses have had to deal mainly with changes in demand and supply chain issues during the pandemic. On the contrary, the determinants associated with competition, and the public manifested themselves less intensely, although they still influenced the business environment. The results show that external factors have played a key role in the adaptation of family businesses to new market conditions.

In our research, we also focused on the external determinants of the macroenvironment (economic, socio-cultural, demographic, political-legal, technological-innovative, ecological). The results show that during the pandemic, economic and political-legal determinants increased most significantly, which significantly affected family businesses. Economic determinants were perceived as a challenge by 48 companies before the pandemic, with their number rising to 147 during the pandemic, indicating widespread financial and market problems. The political and legal determinants increased from 59 to 151 enterprises, which may be related to stricter regulations and uncertainty in the legislative environment. A significant increase was also recorded in technological and information determinants, where the number of companies facing this challenge increased from 78 to 143, which points to accelerated digitization and the need to adapt to new technological requirements. Socio-cultural determinants deepened from 83 to 142 enterprises, which may reflect changes in customer behaviour or deterioration of interpersonal relationships in the business environment.

Using the analysis of variance, we found that no statistically significant differences were found between the individual external determinants of the macroenvironment at the significance level of 5% ($p = 0.184$). This suggests that family businesses perceived economic, political-legal, socio-cultural, technological-informational, demographic and ecological determinants relatively equally, with none of them perceived as a dominant challenge compared to the others.

4. Discussion

The results of the questionnaire survey clearly demonstrated that the determinants of family businesses are key factors affecting their stability and ability to adapt to unexpected changes. The COVID-19 pandemic has shown that, while family businesses have considerable flexibility and resilience, their operations are vulnerable to factors that alter their ability to be adaptable and competitive. The results show that respondents have actually felt the pandemic impact on their business, which has affected their ability to function. This finding coincides with the work of authors Fairlieh and Fossen (2021), who found that COVID-19 led to a massive decline in business activity. Similarly, Meyer et al. (2020) points to the fact that businesses perceived the pandemic mainly as a demand shock, weakening consumer demand and financial stability of businesses. The survey also showed that the majority of respondents were not satisfied with the government measures taken to mitigate the effects of the pandemic situation on Slovak businesses. As reported by Gajdošíková et al. (2022), businesses in the construction sector in Slovakia faced significant financial and operational challenges, with many of them having to reduce or completely stop their activities. The claim is also supported by a study by Valášková et al. (2023), where they concluded that the pandemic has significantly affected the indebtedness of companies through an analysis of the financial performance of Slovak companies. The findings also point to the fact that most of the enterprises benefited from their own resources. The authors Belas et al. (2022) confirm this statement by conducting research that examined the impact of the pandemic on selected areas of management in small and medium-sized enterprises in the Czech Republic and Slovakia. From the point of view of the internal determinants of family businesses, it was clearly demonstrated that the determinants of marketing, finance and human resources were most significantly affected. Authors Čepel et al. (2020) agree with this statement, adding that businesses needed to clearly rethink their financial and HR strategies. Belas et al. (2022) add that crisis management was primarily focused on cash flow stabilization and cost optimization, where only a small proportion of enterprises focused their investments on innovation or digitalization. From the point of view of external microeconomic determinants, suppliers, customers and competitors have proven to be the most affected determinants on the basis of research. This claim is supported by the work of the authors Gajdošíková et al. (2022), who state that the demand for goods and services has become polarized. At the same time, Belas et al. (2022) add that businesses faced significant supply disruptions, leading to the collapse of supply chains and consumer behaviour. The most affected external determinants of the macroenvironment were economic and political-legal determinants, which significantly affected the stability of the business environment and the ability of enterprises to maintain competitiveness. As Bedianashvili (2022a, 2022b) states, the macroeconomic consequences of the pandemic manifested themselves in the form of a triple economic shock: demand, supply and financial. These factors significantly weakened economic growth and put pressure on businesses in various sectors. Belchior and Teixeira (2021) add that citizens' trust in government measures played a key role in adhering to pandemic measures. In the short term, confidence was manifested through various short-term political effects, but in the long term it depended mainly on the ability of national leaders to deal with the crisis. The pandemic situation represented a crucial test of the resilience of family businesses, and its management depended not only on their internal flexibility and strategic management, but also on the stability of the external business environment and the effectiveness of government measures, which determined their ability to recover and maintain competitiveness in the post-pandemic period.

Conclusion

Based on the research carried out, we concluded that family businesses in Slovakia play a key role in the economy, but their ability to withstand unexpected changes such as the COVID-19 pandemic was significantly influenced by several internal and external determinants. Although these companies have shown considerable flexibility and resilience, their ability to adapt to changing market conditions has been limited mainly by financial constraints and the instability of supply chains.

The results of the research suggest that family businesses perceived the pandemic primarily as a demand and financial shock, with marketing, finance and human resources management being the most significantly affected. In terms of external factors, disrupted supply chains, changes in consumer behaviour and increasing competition proved to have had the most significant impact. The findings point to the fact that family businesses have struggled to adapt to the crisis period through digitalisation, cost optimisation and the introduction of new business models. Nevertheless, only a minority of enterprises actively invested in innovation, indicating persistent barriers to business development and modernization.

An important finding is also the fact that family businesses faced limited support from the state and often had to rely on their own financial resources. This factor may have contributed to higher indebtedness and lower competitiveness of businesses in the post-pandemic period. However, with continued legislative changes and EU support, there is room for family businesses to improve their financial stability, digitalisation and long-term sustainability.

The limitation of this research is the dynamic nature of the external environment, where constantly changing economic and legislative conditions can affect the ability of family businesses to adapt and implement effective strategies to mitigate the effects of crisis situations.

Future research should focus on the long-term impact of crisis situations on the strategic management of family businesses and the identification of key mechanisms to increase their resilience to future economic shocks. Furthermore, future research could focus on agile family business management as an important concept for managing unpredictable situations.

Abstract

Research background: Over the last decade, marketing communication has undergone fundamental changes, especially due to the rise of influencer marketing as a response to declining consumer trust in traditional advertising. Influencers, through their authenticity and close connection with followers, have become key players in shaping consumer preferences – particularly in the fast fashion segment, which is strongly influenced by social media trends and post-pandemic shifts in consumer behavior.
Purpose of the article: The aim of the paper is to identify the impact of influencers on the purchasing behavior of consumers in the Slovak fast fashion market, with a focus on generational differences and key motivational factors.
Methods: The research was conducted using a quantitative method – an online questionnaire distributed through social media platforms. The survey involved 121 participants, primarily from Generation Z, and focused on the frequency of fast fashion purchases, type of influencers followed, key decision-making factors, and perceived trust in influencer content. The analysis was based on descriptive statistics.
Findings & Value added: The results show that most consumers purchase fast fashion items occasionally, and that the number of followers an influencer has is less important than their authenticity and trustworthiness. Micro-influencers emerged as the most influential category. The most decisive factors in consumer purchasing were authentic product reviews and discount codes. The findings provide insight into how brands can effectively tailor their influencer strategies, particularly by partnering with credible micro-influencers to target younger audiences in the post-pandemic landscape.

Keywords: Influencer, Influencer marketing, Consumer, Purchasing behavior, Fast fashion

JEL classification: M30, M31

1. Introduction

Marketing is undergoing significant changes to which brands must respond if they want to attract potential customers. As consumers become increasingly resistant to traditional forms of advertising, brands have had to seek more creative ways to promote their products or services. One such approach is leveraging the ability of influencers to impact their followers' decisions. Therefore, companies have started collaborating with influencers to make use of the relationships they have built with their audiences (Khamis et al., 2017). Influencer marketing can be considered a form of word-of-mouth, where influencers communicate product-related information through their social media channels to their audience (Burešová, 2022). It is a social media marketing strategy based on recommendations and product mentions from influencers.

This type of marketing is currently one of the most widespread forms of marketing communication and represents a significant component of the marketing mix for many companies. A company must choose and motivate the right online influencers to reach their social media followers and thereby promote their offerings. These individuals have a loyal follower base and are perceived as experts in their

* Corresponding author: jakub.horvath@unipo.sk

fields (Leung et al., 2022). It is one of the most effective types of marketing due to the high level of trust influencers have built with their followers. Their recommendations act as social proof for potential brand customers.

This trend, involving influencers, has elevated influencer marketing to a global level, making it a core part of corporate marketing strategies (Leung et al., 2022). An influencer is a person who has the ability to influence the opinions and purchasing decisions of both potential and existing customers. They are individuals who have established credibility in the social media space through their authenticity (Atherton, 2022). Influencers can be real people or virtual characters who have gained significant social influence through their presence on social media.

Through blogging, vlogging, and content on platforms such as Instagram, TikTok, and others, influencers share their daily lives and opinions, creating a unique personality that resonates with their followers (Lee et al., 2020). As social media has evolved, so has the definition of an influencer. Today, anyone with a certain number of followers and influence on social networks can be considered an influencer (Wilkens, 2023). Influencers can also be described as "mini-celebrities" because they form a new group of people capable of shaping public opinion in specific areas.

This trend became more pronounced with the rise of social networks. Celebrities have also been part of this category, often transferring their image to brands in marketing campaigns (Cheah et al., 2019). Many people believe that influencers and celebrities are the same, but they differ significantly in concept. Traditional celebrities are known beyond social media and thus have influence over people who do not use these platforms, whereas influencers are mostly known only to those who actively use social networks (Schouten et al., 2019). Celebrities gain fame based on their professional talent, while influencers achieve popularity by successfully presenting themselves as experts online (Khamis et al., 2017).

Their reputation depends on the type of content they produce and how they communicate with their followers. They usually target specific groups with similar interests. This means that influencers who share their views and values with their followers appear more trustworthy than traditional celebrities, with whom the audience might not resonate (Schouten et al., 2019).

Social media is one of the most popular online marketing tools, with studies indicating it is 20–30% more effective than other online ads (Černikovaitė, 2018). According to Statista (2024), there were over 5 billion internet users worldwide as of October 2024, representing approximately 63.1% of the global population, and 5.22 billion social media users. It is estimated that this number will increase to nearly 6 billion by 2027.

Consumer decision-making processes involve steps that individuals go through when making purchase decisions (Influance, 2024). The literature on online consumer behavior highlights many variables influencing decision-making, including product selection, information search, consumption, and post-purchase satisfaction. Consumer behavior encompasses searching, buying, consuming, and forming opinions about products that meet individual needs. Traditional consumers tend to be more conservative in their purchases, while digital consumers are more open to trying new things (Belingher et al., 2011). They prefer interactive and communicative marketing elements on social media over traditional advertising forms.

Influencer marketing can play a crucial role in each of these stages by providing consumers with information, recommendations, and motivation to make a purchase (Influance, 2024). Consumers prefer content from influencers in the form of videos and photos with explanations, indicating that products recommended by influencers are more attractive and effective in advertising terms.

Metrics such as likes, comments, the use of discount codes, and others are used to measure the impact of influencers on social media, consumer purchasing behavior, and the sales of promoted products (Kavaliauskienė et al., 2019). Influencers play a key role in shaping consumer preferences and demands, directly contributing to increased sales. A survey conducted by Matter (2023) found that up to 81% of consumers said influencer posts on social media had caught their attention and encouraged them to purchase a product or service.

Statistics also show that the most active users follow influencers daily on Instagram (87%), YouTube (65%), and Facebook (58%), often engaging in discussions and interactions (Černikovaitė, 2018). More than 69% of consumers consider influencers a trustworthy source of brand information. They primarily look for influencers with whom they can identify (61%), experts in their field (43%), entertaining

personalities (32%), and ambitious role models (28%). Only 11% prefer well-known celebrities (Matter, 2023).

The core functions of an influencer include communicating with followers, recommending products, advertising in stories, spreading information, and sharing opinions. The para-social relationship between influencers and their audience is a key element of their popularity, as it supports belief in their opinions. This type of relationship creates the illusion of personal communication and helps followers identify with the influencer.

Influencers create and organize content based on the available formats and technologies on social media, and their posting frequency strategy is set to strengthen brand positioning in consumers' minds. Well-planned posts by fashion influencers lead to increased followers and engagement. Therefore, companies that monitor consumer behavior, needs, and preferences gain a competitive advantage (Kotler & Armstrong, 2018).

2. Methods

The aim of this paper is to identify the impact of influencers on the purchasing behavior of consumers in the fast fashion sector on the Slovak market.

Based on this main objective, the following sub-objectives were formulated:

- To determine how often consumers purchase fast fashion products.
- To identify which type of influencers (nano, micro, macro, mega) is the most effective in influencing purchase decisions.
- To determine which influencer attributes (e.g. trustworthiness, authenticity, quality of presentation) most influence consumer purchasing behavior.
- To identify the main reasons why consumers purchase fast fashion products.

As part of this article, a quantitative survey was conducted with the aim of analyzing the impact of fashion influencers on consumer purchasing behavior in the fast fashion segment. Data collection was carried out using an online questionnaire via Google Forms, which was distributed through social media and communication platforms. This method enabled the gathering of relevant data on consumers' shopping behavior, their perception of fashion influencers, and the factors influencing their decisions when purchasing fast fashion products.

The questionnaire consisted of 20 questions, including closed-ended multiple-choice items as well as questions based on Likert scales and linear scales. The questions were designed to meet the objectives of the article and to allow for an in-depth analysis of the influence of influencers on consumer decision-making in the fast fashion sector. The questionnaire was divided into three main sections:

- Demographic data, covering age, gender, place of residence, level of education, and income;
- Respondents' relationship to fast fashion influencers, including the frequency of following influencers on social media, the number of influencers followed, and the frequency of purchases based on their recommendations;
- The influence of influencers on purchasing behavior, where factors such as trust in influencers, preferred forms of influencer marketing, perception of the quality of recommended products, and overall purchasing decisions were evaluated.

The survey participants were fast fashion consumers, with the target group consisting of individuals with a positive attitude toward fast fashion and who follow fashion influencers on social media. The sample was selected using a non-probability sampling method, specifically purposive sampling, targeting respondents who met the criteria of interest in fast fashion and influencer following. The research primarily focused on Generation Z, as this demographic is the most active on social media and the most frequent buyers of fast fashion products. Geographically, the research was conducted mainly in the eastern region of Slovakia.

The data analysis highlights the key findings of the survey and is presented in the form of descriptive statistics, primarily using tables.

A total of 121 respondents participated in the survey. For clarity, the number and percentage representation of each gender were processed into a summary table. The majority of respondents were women, totaling 78, which represents 64.5% of the total sample. Men accounted for 43 responses, or 35.5% of the total. The "other" gender option was not selected by any respondent.

The results indicate that the survey primarily reached female participants, which may be attributed to the fact that fast fashion influencer marketing is predominantly targeted at this demographic. Nevertheless, the participation of male respondents provides a more comprehensive view of influencer impact across different consumer segments. The total number of responses corresponds exactly to the number of respondents, ensuring the accuracy and reliability of the data.

The results presented in this paper are part of a broader study, with additional interesting findings discussed in the conclusion of the article. From an age perspective, the largest group of respondents belonged to Generation Z (aged 16 to 30), totaling 114 individuals, which constitutes 94.21% of the total sample. The second largest group comprised Millennials (aged 31 to 45), with 6 respondents (4.96%), and there was 1 respondent from Generation X (0.83% of the sample).

3. Results

This chapter presents the survey results through descriptive statistics, mainly in the form of tables.

Table 1. Frequency of Fast Fashion Purchases

PURCHASE FREQUENCY	NUMBER OF RESPONSES	PERCENTAGE
Very rarely	29	23,97 %
Rarely	18	14,88 %
Occasionally	42	34,71 %
Often	28	23,14 %
Very often	4	3,31 %
TOTAL	**121**	**100 %**

Source: own elaboration (2025)

The largest group of respondents purchases clothing from fast fashion stores occasionally (several times per quarter); this option was selected by 42 respondents (34.71%). On the other hand, 29 respondents (23.97%) shop very rarely (a few times a year). Another 28 respondents (23.14%) reported shopping frequently (several times a month). A further group of 18 respondents (14.88%) indicated they shop rarely (a few times per half-year). The smallest group, 4 respondents (3.31%), reported shopping very often (several times a week). These results show that most respondents purchase fast fashion occasionally, with quarterly frequency being the most common. Monthly purchases are less frequent, indicating that fast fashion remains popular, but consumers generally approach their purchases rationally rather than impulsively or excessively.

Table 2. Types of Followed Fast Fashion Influencers

TYPE OF INFLUENCERS FOLLOWED	NUMBER OF RESPONSES	PERCENTAGE
Nano-influencers	5	4,13 %
Micro-influencers	30	24,8 %
Macro-influencers	21	17,36 %
Mega-influencers	2	1,7 %
Follower count does not matter	63	52,01 %
TOTAL	**121**	**100 %**

Source: own elaboration (2025)

The results revealed that as many as 52.01% of respondents do not consider the follower count of an influencer to be important. However, micro-influencers have a significant influence on purchasing decisions, as preferred by 30 respondents (24.8%). The next influential group were macro-influencers (21 respondents, 17.36%). Nano-influencers influence 4.13% of respondents, while mega-influencers were considered the most influential by only 1.7% of respondents. These results indicate that follower count is not a key factor for most respondents. Instead, consumers prioritize authenticity and trustworthiness over popularity, with micro-influencers having the greatest influence. For brands, this suggests that more effective collaborations may be achieved with smaller but more credible content creators.

Table 3. Factors Influencing Purchase Decisions

FACTORS INFLUENCING PURCHASE	NUMBER OF RESPONSES	PERCENTAGE
Trustworthiness	42	34,71 %
Authentic review	70	57,85 %
Quality of presentation	60	49,59 %
Discount code	61	50,41 %
None of the above	2	1,6 %

Source: own elaboration (2025)

The most significant factor influencing purchases based on recommendations from fast fashion influencers is an authentic review, selected by 70 respondents (57.85%). Interestingly, 50.41% of respondents indicated they were influenced by a discount code. The third most influential factor was the quality of product presentation (60 respondents, 49.59%). Trustworthiness was cited by 42 respondents (34.71%), and only 2 respondents (1.6%) reported that none of the listed factors influenced their purchase decisions. These findings suggest that consumers place the greatest trust in authentic reviews when buying products recommended by influencers. Discount codes are also an important motivational factor, enhancing the appeal of purchases.

Table 4. Reasons for Purchasing Fast Fashion

REASONS FOR PURCHASE	NUMBER OF RESPONSES	PERCENTAGE
Availability & wide selection	93	76,86 %
Low price	72	59,50 %
Trendy design	60	49,59 %
Fast-changing collections	35	28,93 %
Influence of influencers	13	10,74 %
Other	2	1,65 %

Source: own elaboration (2025)

The most common reason for purchasing fast fashion products is their availability and wide selection, marked by 93 respondents (76.86%). The second most cited reason is the low price (72 respondents, 59.50%). In third place was the trendy design of fast fashion products (60 respondents, 49.59%). Another significant reason was the fast turnover of collections (35 respondents, 28.93%), while 13 respondents (10.74%) stated that influencer or social media influence was the primary reason. Two respondents selected "other." Overall, consumers perceive fast fashion primarily as an affordable option with a varied and trendy selection. Rapid collection turnover and up-to-date design are also important considerations.

4. Discussion

The findings of this study support current academic and practical insights into the influence of social media influencers on consumer behavior, particularly within the fast fashion segment. The results indicate that authenticity, personal experiences shared by influencers, and practical value of content—such as reviews and styling tips—play a key role in purchase decision-making. These observations align with existing research emphasizing the growing importance of trustworthiness in digital marketing (e.g., Khamis et al., 2017; Atherton, 2022).

An interesting aspect of the survey is the clear preference for micro-influencers, who proved to be more effective than macro- or mega-influencers. This trend can be interpreted as a result of a stronger para-social relationship between smaller influencers and their followers, fostering a sense of intimacy and trust. In the context of the Slovak population, particularly among Generation Z, this is crucial, as this demographic tends to be highly digitally literate and more sensitive to marketing tactics.

Another important finding is that most respondents do not shop impulsively, but purchase fast fashion items only occasionally. This suggests a shift toward more conscious consumer behavior, even within a segment often associated with rapid consumption. This shift could reflect growing environmental and social awareness among consumers.

Notably, the number of followers is not a decisive factor for most consumers, which contrasts with earlier research that emphasized reach as the primary indicator of influence. The results suggest that the quality of the relationship between influencer and audience matters more than quantitative metrics. Therefore, brands should consider not only the size of an influencer's audience, but also their communication style and level of engagement.

From a practical standpoint, the findings suggest that fast fashion brands should invest in long-term and transparent collaborations with influencers who build trust through consistent and authentic content. At the same time, they should focus on formats that promote personal connection, such as videos, Q&A sessions, and behind-the-scenes content.

Conclusion

This study confirmed that influencer marketing plays a significant role in shaping consumer behavior in the fast fashion sector, particularly among Generation Z. The findings highlight that authenticity, credibility, and practical content formats are the most influential factors in consumers' purchasing decisions. Micro-influencers, despite having smaller audiences, generate a greater impact due to their perceived trustworthiness and personal approach.

The research also revealed a trend toward more deliberate and rational shopping behavior, even in a market segment traditionally associated with fast consumption. This presents both a challenge and an opportunity for brands seeking to adapt their influencer strategies to evolving consumer expectations.

Future research should expand the sample size and geographic scope, and consider longitudinal studies to capture shifts in consumer attitudes over time. Additionally, examining the role of sustainability communication by influencers may offer valuable insights, as consumers become more environmentally conscious.

Verbal Communicative Strategies in Intercultural Business Communication: a Theoretical Perspective

***Irina* Kozárová**[1,*]

[1] University of Prešov in Prešov, Faculty of Management and Business, Department of Intercultural Communication, Konštantínova 16, 080 01 Prešov, Slovakia

Abstract

Research background: The current global instability and uncertainty underlines the importance of effective intercultural business communication. The intercultural communication effectiveness, however, is not an outcome of global interaction itself but rather a result of developing intercultural communicative competence, including strategic competence as its integral component. Verbal communicative strategies should help manage the complexities and potential misunderstandings inherent in intercultural encounters. Numerous approaches exist in the academic literature concerning the definition and taxonomy of verbal communicative strategies in various contexts. However, the conceptualization of these strategies lacks uniformity, exhibiting significant diversity across various theoretical frameworks. Therefore, a systematic overview of the existing knowledge on this topic relevant to intercultural business communication would be beneficial.
Purpose of the article: The aim of the paper is to identify existing definitions and taxonomies of verbal communicative strategies used in intercultural communication and identify key verbal communicative strategies relevant to intercultural business communication.
Methods: The paper employs an analytical method to examine the literature on intercultural communication, business communication, sociolinguistics, and pragmatics and to identify relevant verbal strategies.
Findings & Value added: The paper identifies several crucial verbal communicative strategies for managing intercultural business communication. These include question strategies, inserting interim summaries, and avoiding adjectives and adverbs referring to relative sizes. The theoretical contribution provides a foundation for future empirical research and the development of practical guidelines for management and business students and professionals operating in diverse intercultural environments.

Keywords: Intercultural business communication, Verbal communicative strategies, Theoretical perspective

JEL classification: D83

1. Introduction

In the process of globalization, societies are becoming more interconnected, integrated, and interdependent (Neugebauer & Vokoun, 2024). The rise of such complexity is, however, accompanied by the increasing intensity of global uncertainty (Urteaga, 2023). In the present, such uncertainty is often described, for example, in terms of economic uncertainty (Tang & Cao, 2025), global financial uncertainty (Caggiano & Castelnuovo, 2023), techno-geopolitical uncertainty (Luo & Van Assche, 2023), energy-related uncertainty (Dang et al., 2023), uncertainty arising from climate change (Baum, 2024) or intercultural encounter (Prechtl & Lund, 2007).

Effective intercultural communication is considered to be one of the possible ways how to address uncertainty at personal, interpersonal, and international levels in various situations and environments (Baldwin et al. 2023), including the environments of business (for the role of effective intercultural communication in the sphere of business, see, e.g., Ng & Lillevik, 2017) and management (for the role of

* Corresponding author: irina.kozarova@unipo.sk

effective intercultural communication in organizations, see, e.g., Tocar, 2024). Intercultural communication effectiveness, however, is not merely an outcome of global interaction itself; it is rather the result of cultivating intercultural communicative competence, which is not innate but must be learnt deliberately (Liu et al. 2023).

Intercultural communicative competence consists of several components comprising, inter alia, strategic competence, which refers to the knowledge of verbal and non-verbal communicative strategies to overcome communication difficulties and improve the effectiveness of communication (Yao & Du-Babcock, 2023). As using verbal code in communication is primary in organizations, and especially in business operations, verbal communicative strategies seem to be crucial to help manage the complexities and potential misunderstandings that may arise from intercultural communication. The academic literature contains a plethora of approaches to the definition and taxonomy of verbal communicative strategies in a variety of contexts. However, the conceptualization of these strategies is inconsistent, displaying considerable variation among different theoretical frameworks. Therefore, a systematic review of the current knowledge on this subject pertinent to intercultural business communication would be beneficial.

The paper aims to identify existing definitions and taxonomies of verbal communicative strategies used in intercultural communication and identify key verbal communicative strategies relevant to intercultural business communication.

2. Methods

The paper employs an analytical method to examine the literature on intercultural communication, business communication, sociolinguistics, and pragmatics accessible in databases such as *Web of Science*, *Scopus*, *SpringerLink*, *ProQuest Central*, *Google Books*, *Google Scholar*, and *Semantic Scholar* and to identify relevant aspects of verbal communicative strategies.

3. Results and Discussion

The results of the analysis indicate that definitions of verbal *communicative strategies* are dependent on the definitions of a broader concept of *communicative strategies*. In the examined academic literature, at least five distinct understandings of communicative strategies were identified.

One of the broadest understandings refers to communicative strategies as "language use strategies". In this sense, communicative strategies are defined as "techniques that learners employ when attempting to use the target language for the purpose of communication" (Oxford, 2004, p. 130). This understanding of communicative strategies is based on Cohen's (1998) concept of *language use strategies*. Nevertheless, Cohen himself did not prefer to use the term *communicative strategies*. It is also worth noting that a considerable debate is ongoing among scholars regarding whether *language use strategies* overlap with or differ from *language learning strategies* (Oxford, 2017). According to Oxford (2004), language use strategies and language learning strategies overlap, which makes her understanding of communicative strategies one of the most comprehensive. See Table 1 for Oxford's taxonomy of communicative strategies.

Table 1. Oxford's taxonomy of communicative strategies

Type of communicative strategies	**Subtype of communicative strategies**	**Communicative strategies**
Retrieval (mnemonic) strategies		Mnemonic strategy creating retrieval via - an orderly string (acronyms) - sounds - images - a combination of sounds and images - body movement - mechanical means - location
Rehearsal (practice) strategies		Grammatical rehearsal Vocabulary rehearsal Pronunciation rehearsal
Cover (masking or image-protection) strategies	*Linguistically-based cover strategies*	Using a memorized and partly understood phrase to keep the conversation going Producing simplified utterances Producing overly complex utterances

	Social-psychological cover strategies	Laughting Joking Diverting the conversation partner Smiling Nodding The appearing to be interested or fascinated by the conversation while not understanding what it being said
'Communication' (restricted-knowledge) strategies		Overgeneralising a grammar rule or vocabulary meaning from one context to another when it does not apply Avoiding or abandoning a topic that is too difficult Reducing a message Code switching Paraphrasing Using circumlocution

Source: adapted by the author from Oxford (2004)

Related to the previous one is the understanding of communicative strategies as a synonym for "communication strategies" and "problem-solving mechanisms" (Brunner, 2021). This understanding follows Tarone's (1977, p. 195) definition of communication strategies. According to him, "conscious communication strategies are used by an individual to overcome the crisis which occurs when language structures are inadequate to convey the individual's thought". This definition has evolved and has been elaborated upon, incorporating both linguistic and psychological approaches. The result of this process is a wide range of definitions and overlapping taxonomies using different terminology. An overview of such definitions and taxonomies was elaborated, e.g., by Dörneyi and Scott (1997) or Brunner (2021). See Table 2 for Dörneyi and Scott's taxonomy of communication strategies.

Table 2. Dörneyi and Scott's taxonomy of communication strategies

Type of communicative strategies	Subtype of communicative strategies	Communicative strategies
Direct strategies	*Resource deficit-related strategies*	Message abandonment Message reduction Message replacement Circumlocution Approximation Use of all-purpose words Word-coinage Restructuring Literal translation Foreignizing Code-switching Use of similar sounding words Mumbling Omission Retrieval Mime
	Own-performance problem-related strategies	Self-rephrasing Self-repairing
	Other-performance problem-related strategies	Other-repair
Interactional strategies	*Resource deficit-related strategies*	Appeals for help
	Own-performance problem-related strategies	Comprehension check Own-accuracy check
	Other-performance problem-related strategies	Asking for repetition Asking for clarification Asking for confirmation

		Guessing Expressing nonunderstanding Interpretive summary Responses
Indirect strategies	*Processing time pressure-related strategies*	Use of fillers Repetitions
	Own-performance problem-related strategies	Verbal strategy markers
	Other-performance problem-related strategies	Feigning understanding

Source: adapted by the author from Dörneyi and Scott (1997)

Another understanding of communicative strategies is close to Gumperz's (1982) understanding of "discourse strategies". Using the term *communicative strategies* in this sence, Platt (1989, pp. 13–14) defines communicative stratgies as "verbal and/or non-verbal rule-governed behaviour in interpersonal exchanges which, on the one hand, serves to convey a message, [...] and, on the other hand, serves to establish or re-establish interpersonal relationships." At the same time, he identifies six sensitivity areas and possible problems in balancing interpersonal relationships, as, according to him, the communication problems may arise due to the use of inappropriate (or 'other-system') strategies or inappropriate interpretation of strategies. Platt thus elaborated on the taxonomy of sensitivity areas and possible problems rather than the taxonomy of communicative strategies; however, this taxonomy can be extended with some appropriate strategies mentioned in his text. See Table 3 for the extended taxonomy.

Table 3. Platts's extended taxonomy of sensitivity areas, communication problems and communicative strategies

Sensitivity area	Communication problems	Communicative strategies
Engaging (starting a verbal exchange)	First presentation of ego Placement of alter ego by ego Effecting the placement of ego by alter ego	Greeting routines The decision whether or not to engage
Disengaging (ending a verbal exchange)	A deliberate withdrawal automatically puts ego higher than alter ego, cushioning effect is needed	Disengagement routine
Requesting something from someone or requesting someone to do something	Putting ego in 'vulnerable' position (e.g. alter ego may refuse request) but also involving threat to alter ego	Requesting conventions
Acceding to a request	Placement of ego and alter ego	Appropriate verbalizing or non-verbalizing of willingness or ability to execute request
Positive responding to an offer or invitation	Balancing problem – do not want to push ego up or down excessively	Appropriate accepting strategy depending on communicative and culture system
Negative responding to an offer or invitation	Balancing problem – do not want to push ego down excessively	Appropriate 'cushioning' strategy

Source: adapted and extended by the author from Platt (1989)
